Behind the first stage of multistage axial turbines with untwisted blades, a certain flow pattern occurs which practically is repeated behind each of the succeeding homogeneously constructed stages. Consequently, the blade circulations of both the stator and rotor rows are approximately constant over the entire blade length except for the first stage. With regard to blade circulation there is, therefore, no need to consider the more expensive free-vortex blading with constant circulation over the blade length as being more advantageous compared with the essentially simpler untwisted blading. Untwisted blading is understood to include all blade shapes with a constant outlet angle over the entire blade length.

N-47547*

THE EFFECT OF DEFORMATION ON THE POTENTIALS OF METALS. (Vliyanie deformatsii na potentsialy metallov). E. M. Zaretskii. 18p. diagrs., photo. (Translation from Zhurnal Prikladnoi Khimii, v. 24, no. 6, 1951, p. 614-623)

The effect of deformation on the electrical characteristics of several rolled industrial metals is investigated. The change in the electrode potentials of magnesium, magnesium alloys MA1 and MA3, aluminum, steel, copper, and zinc was studied under the action of deformation. Several tests were conducted on a model voltaic cell of magnesium alloys.

NACA RM A50I14

WIND-TUNNEL INVESTIGATION AT LOW SPEED OF A WING SWEPT BACK 63° AND TWISTED AND CAMBERED FOR UNIFORM LOAD AT A LIFT COEFFICIENT OF 0.5 AND WITH A THICKENED TIP SECTION. James A. Weiberg and Hubert C. Carel. November 21, 1950. 42p. diagrs., photo., tabs. (NACA RM A50I14)

The results of force and pressure distribution measurements showed that an increase in thickness and a minor change of twist from midsemispan to the tip of a semispan model of a wing with the leading edge swept back 63° did not result in improved longitudinal-stability characteristics of the wing. The modification reduced the nose pressure peaks with no resulting improvement of tip lift characteristics indicating that the early loss of lift of the tip is due more to spanwise flow than local stall. By adding flaps and fences to the wing the adverse effects of spanwise boundary-layer flow and separation on the longitudinal stability of the wing were delayed to higher angles of attack.

NACA RM A50J17

A COMPARISON OF THE EXPERIMENTAL AND THEORETICAL LOADING OVER TRIANGULAR WINGS AT SUPERSONIC SPEEDS. John W. Boyd and E. Ray Phelps. January 3, 1951. 42p. diagrs., photos., tabs. (NACA RM A50J17)

The results of an experimental investigation of the pressure distribution over two triangular wings at Mach numbers from 1.20 to 1.70 are presented and compared with theory. The two wings tested have identical plan form, 45° sweepback of the leading edge, and an aspect ratio of 4.0, but different airfoil sections. One model was composed of round-nose airfoil sections and the other of sharp-nose, biconvex sections, 6 percent thick in streamwise planes.

NACA RM A50K20

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - PLANE TRIANGULAR WING OF ASPECT RATIO 2 WITH NACA 0008-63 SECTION. Donald W. Smith and John C. Heitmeyer. February 1, 1951. 22p. diagrs., photo. (NACA RM A50K20)

This paper contains the results of an investigation to ascertain the lift, drag, and pitching moment of a wing-body combination having a plane triangular wing of aspect ratio 2 and NACA 0008-63 sections in streamwise planes. Results are shown for Mach numbers from 0.24 to 1.70 at a Reynolds number of 3.0 million. The variations of the characteristics with Reynolds number are also shown for several Mach numbers.

NACA RM A53I17

A STUDY OF THE EFFECTS OF BODY SHAPE ON THE VORTEX WAKES OF INCLINED BODIES AT A MACH NUMBER OF 2. Forrest E. Gowen and Edward W. Perkins. December 1953. 25p. diagrs., photos. (NACA RM A53I17)

A study of the wake of a number of bodies of revolution at moderate and large angles of attack was made at a Mach number of 1.98 by use of a visual-flow technique. It was found that the angle of attack at which the crossflow wake became unsteady was increased by reducing the nose fineness ratio, or for a given fineness ratio, by changing the nose shape to a more blunt profile.

NACA RM A53I21

WIND-TUNNEL INVESTIGATION OF A 45° SWEPTBACK WING HAVING A SYMMETRICAL ROOT AND A HIGHLY CAMBERED TIP, INCLUDING THE EFFECTS OF FENCES AND LATERAL CONTROLS. Joseph W. Cleary and Lee E. Boddy. November 1953. 52p. diagrs., photo. (NACA RM A53I21)

A wind-tunnel investigation at subsonic Mach numbers has been made of the aerodynamic characteristics of a 45° sweptback wing-body combination having varying camber along the span. The results show the effects of fences on the longitudinal characteristics and the longitudinal and lateral control characteristics of an aileron and two types of spoilers. The longitudinal characteristics are compared with those of two other wings having the same plan form, one without camber, the other with uniform camber.

NACA RM A53J14

THE EFFECTS OF CIRCULAR END PLATES ON THE LIFT, DRAG, AND PITCHING MOMENT AT SUBSONIC AND SUPERSONIC SPEEDS ON A MODIFIED TRIANGULAR WING HAVING AN ASPECT RATIO OF 2, A TAPER RATIO OF 0.33, AND A 45° SWEPT LEADING EDGE. Robert B. Petersen. March 1954. 16p. diagrs., tab. (NACA RM A53J14)

The effects of circular end plates on the longitudinal aerodynamic characteristics of a modified triangular wing of aspect ratio 2 are presented for subsonic and supersonic Mach numbers at a Reynolds number of approximately 4×10^6. The aerodynamic characteristics investigated are center-of-pressure position, lift-curve slope, maximum lift-drag ratio, minimum drag, and lift coefficient at which the maximum lift-drag ratio occurs.

NACA RM E7I05

THEORETICAL ANALYSIS OF THE PERFORMANCE OF A SUPERSONIC DUCTED ROCKET. Reece V. Hensley. February 13, 1948. 32p. diagrs. (NACA RM E7I05)

Presents theoretical analysis, considering variation of specific heats, of performance of a ducted rocket at supersonic flight velocities. Analysis is based on a gasoline-liquid oxygen rocket. Considerable increases in thrust above the thrust of the rocket alone or the thrust of a ram jet of a size comparable to the ducted rocket could be obtained with a fuel consumption intermediate between those of a rocket and a ram jet operating under similar flight conditions.

NACA RM E7I30

PRELIMINARY ESTIMATE OF PERFORMANCE OF A TURBOJET ENGINE WHEN INLET PRESSURE IS REDUCED BELOW EXHAUST PRESSURE. H. D. Wilsted and W. D. Stemples. February 18, 1948. 42p. diagrs. (NACA RM E7I30)

Investigations of a turbojet engine were conducted with reduced compressor-inlet pressures to simulate operation with inlet-duct losses with two different area jet nozzles. Thrust and air consumption decreased rapidly with decreasing inlet pressure and operating temperatures and specific fuel consumption increased sharply. Small improvements in inlet pressure recovery were shown to appreciably decrease length of take-off run. Data are applicable to use of turbojet engine as a pump for removing boundary-layer air from wing surfaces and to the problem of inlet throttling as a means of thrust control.

NACA RM E8I17a

THEORETICAL PERFORMANCE OF DIBORANE AS A ROCKET FUEL. Vearl N. Huff, Clyde S. Calvert, and Virginia C. Erdmann. January 10, 1949. 31p. diagrs., tabs. (NACA RM E8I17a)

Theoretical performance data including nozzle-exit temperature, specific impulse, and volume specific impulse based on frozen and equilibrium expansion are presented for four rocket propellant combinations at a pressure of 20.4 atmospheres. Composition of reaction products is given. Based on maximum specific impulse, the order of four oxidants reacting with diborane was: liquid fluorine, liquid fluorine oxide, liquid oxygen, and 100-percent hydrogen peroxide. Based on maximum calculated volume specific impulse, order of four oxidants with diborane was: liquid fluorine oxide, liquid fluorine, 100-percent hydrogen peroxide, and liquid oxygen.

NACA RM E50C30

EFFECT OF COMBUSTION-CHAMBER PRESSURE AND NOZZLE EXPANSION RATIO ON THEORETICAL PERFORMANCE OF SEVERAL ROCKET PROPELLANT SYSTEMS. Virginia E. Morrell. May 25, 1950. 15p. diagrs., tabs. (NACA RM E50C30)

Theoretical calculations of specific impulse to determine the separate effects of increasing the combustion-chamber pressure and the nozzle expansion ratio on the performance of the propellants, hydrogen-fluorine, hydrogen-oxygen, ammonia-fluorine and AN-F-58 fuel - white fuming nitric acid (95 percent). The results indicate that an increase in specific impulse obtainable with an increase in combustion-chamber pressure is almost entirely caused by the increased expansion ratio through the nozzle.

NACA RM E50I18

FACTORS IN SELECTING FUELS FOR GAS-TURBINE POWERED AIRCRAFT. Louis C. Gibbons. November 13, 1950. 85p. diagrs., photos., tabs. (NACA RM E50I18)

The problems associated with the selection of fuels for gas-turbine aircraft are briefly discussed. The loss of fuel by high-performance aircraft during climb, and the performance of fuels of varying volatility and composition in gas-turbine engines are considered. The potential availability of fuels at various volatility levels is also considered. Low-volatility fuels would minimize fuels losses during climb and would give good combustion efficiencies and altitude operational limits. Low-volatility fuels would be more difficult to start and would tend to deposit more carbon than volatile fuels.

NACA RM E51C01

THEORETICAL PERFORMANCE OF LITHIUM AND FLUORINE AS A ROCKET PROPELLANT. Sanford Gordon and Vearl N. Huff. May 10, 1951. 22p. diagrs., tabs. (NACA RM E51C01)

Theoretical performance for liquid lithium and liquid fluorine as a rocket propellant was calculated with assumptions both of equilibrium and frozen composition during expansion. Parameters included were specific impulse, combustion-chamber temperature, nozzle-exit temperature, composition, mean molecular weight, characteristic velocity, coefficient of thrust, and ratio of nozzle-exit area to throat area. For chamber pressure of 300 pounds per square inch absolute and expansion to 1 atmosphere, the maximum

equilibrium specific impulse calculated was 335.5 pound-seconds per pound. The effect of ionization on calculated performance was shown to be negligible by comparison of values of various parameters calculated both with and without ionized products of combustion.

NACA RM E51I06

STEADY-STATE ENGINE WINDMILLING AND ENGINE SPEED DECAY CHARACTERISTICS OF AN AXIAL-FLOW TURBOJET ENGINE. A. E. Sobolewski and J. M. Farley. December 1951. 20p. diagrs., photo. (NACA RM E51I06)

A wind-tunnel investigation has been conducted to determine the steady-state windmilling and engine speed decay characteristics of the J34-WE-32 turbojet over a range of altitudes from 5000 to 50,000 feet and simulated flight Mach numbers from 0.19 to 1.06. The effect of an engine accessory load on the speed decay characteristics was also determined. The accessory load was about 7.8 horsepower for engine speeds above 4000 rpm and decreased with decreasing engine speed. An analysis of the speed decay data was made and engine speed decay rates were determined for hypothetical accessory loads up to 40 horsepower.

NACA RM E51I24

PRELIMINARY INVESTIGATION OF A TRANSLATING COWL TECHNIQUE FOR IMPROVING TAKE-OFF PERFORMANCE OF A SHARP-LIP SUPERSONIC DIFFUSER. Edgar M. Cortright, Jr. November 1951. 11p. diagrs., photos. (NACA RM E51I24)

A preliminary investigation was conducted in quiescent air on a translating cowl technique for improving the take-off performance of a sharp-lip supersonic diffuser. The technique consists of cutting the cowling in a plane normal to its axis and then translating the forepart of the cowling in the forward direction. The leading edge of the fixed portion of the cowling is rounded. Appreciably improved inlet performance was obtained with a cowling translation corresponding to a gap of only 1/4 inlet radius.

NACA RM E51L11

THEORETICAL PERFORMANCE OF LIQUID AMMONIA, HYDRAZINE, AND MIXTURE OF LIQUID AMMONIA AND HYDRAZINE AS FUELS WITH LIQUID OXYGEN BIFLUORIDE AS OXIDANT FOR ROCKET ENGINES. I - MIXTURE OF LIQUID AMMONIA AND HYDRAZINE. Vearl N. Huff and Sanford Gordon. February 1952. 24p. diagrs., tabs. (NACA RM E51L11)

Theoretical performance for mixture of 36.3 percent liquid ammonia and 63.7 percent hydrazine with liquid oxygen bifluoride as rocket propellant was calculated on assumption of equilibrium composition during expansion for a wide range of fuel-oxidant and expansion ratios. Parameters included were specific impulse, combustion-chamber temperature, nozzle exit temperature, composition, mean molecular weight, characteristic velocity, coefficient of thrust, and ratio of nozzle-exit area to throat area. For chamber pressure of 300 pounds per square inch absolute and expansion to 1 atmosphere, maximum specific impulse was 295.8 pound-seconds per pound. Five percent by weight of water in the hydrazine lowered specific impulse from about one to three units over a wide range of weight-percent fuel.

NACA RM E52G09

THEORETICAL PERFORMANCE OF LIQUID AMMONIA, HYDRAZINE, AND MIXTURE OF LIQUID AMMONIA AND HYDRAZINE AS FUELS WITH LIQUID OXYGEN BIFLUORIDE AS OXIDANT FOR ROCKET ENGINES. II - HYDRAZINE. Vearl N. Huff and Sanford Gordon. September 1952. 20p. diagrs., tabs. (NACA RM E52G09)

Theoretical performance of hydrazine with liquid oxygen bifluoride as a rocket propellant was calculated for a wide range of fuel-oxidant and expansion ratios on the assumption of equilibrium composition during expansion. Parameters included were specific impulse, combustion-chamber temperature, nozzle exit temperature, equilibrium composition, mean molecular weight, characteristic velocity, coefficient of thrust, and ratio of nozzle-exit area to throat area. For chamber pressure of 300 pounds per square inch absolute and expansion to 1 atmosphere, maximum specific impulse was 298.7 pound-seconds per pound. The presence of 5 percent by weight of water in the hydrazine lowered specific impulse from 2 to 5 units over a wide range of fuel-oxidant and expansion ratios.

NACA RM E52H14

THEOREITCAL PERFORMANCE OF LIQUID AMMONIA, HYDRAZINE, AND MIXTURE OF LIQUID AMMONIA AND HYDRAZINE AS FUELS WITH LIQUID OXYGEN BIFLUORIDE AS OXIDANT FOR ROCKET ENGINES. III - LIQUID AMMONIA. Vearl N. Huff and Sanford Gordon. October 1952. 15p. diagrs., tabs. (NACA RM E52H14)

Theoretical values of performance parameters for liquid ammonia with liquid oxygen bifluoride were calculated on the assumption of equilibrium composition during the expansion process for a wide range of fuel-oxidant and expansion ratios. Parameters included were specific impulse, combustion-chamber temperature, nozzle-exit temperature, equilibrium composition, mean molecular weight, characteristic velocity, coefficient of thrust, and ratio of nozzle-exit area to throat area. The maximum value of specific impulse was 291.6 pound-seconds per pound for a chamber pressure of 300 pounds per square inch absolute (20.41 atm) and an exit pressure of 1 atmosphere.

NACA RM E52L11

THEORETICAL PERFORMANCE OF LIQUID HYDROGEN AND LIQUID FLUORINE AS A ROCKET PROPELLANT. Sanford Gordon and Vearl N. Huff. February 1953. 28p. diagrs., tabs. (NACA RM E52L11)

Theoretical values of performance parameters for liquid hydrogen and liquid fluorine as a rocket propellant were calculated on the assumption of equilibrium composition during the expansion process for a wide range of fuel-oxidant and expansion ratios. The parameters included were specific impulse, combustion-chamber temperature, nozzle-exit temperature, equilibrium composition, mean molecular weight, characteristic velocity, coefficient of thrust, ratio of nozzle-exit area to throat area, specific heat at constant pressure, coefficient of viscosity, and coefficient of thermal conductivity. The maximum value of specific impulse was 364.6 pound-seconds per pound for a chamber pressure of 300 pounds per square inch absolute (20.41 atm) and an exit pressure of 1 atmosphere.

NACA RM E53A26

THEORETICAL PERFORMANCE OF LIQUID AMMONIA AND LIQUID FLUORINE AS A ROCKET PROPELLANT. Sanford Gordon and Vearl N. Huff. March 1953. 25p. diagrs., tabs. (NACA RM E53A26)

Theoretical values of performance parameters for liquid ammonia and liquid fluorine as a rocket propellant were calculated on the assumption of equilibrium composition during the expansion process for a wide range of fuel-oxidant and expansion ratios. The parameters included were specific impulse, combustion chamber temperature, nozzle-exit temperature, equilibrium composition, mean molecular weight, characteristic velocity, coefficient of thrust, ratio of nozzle-exit area to throat area, specific heat at constant pressure, coefficient of viscosity, and coefficient of thermal conductivity. The maximum value of specific impulse was 311.5 pound-seconds per pound for a chamber pressure of 300 pounds per square inch absolute (20.41 atm) and an exit pressure of 1 atmosphere.

NACA RM E53E12

THEORETICAL PERFORMANCE OF LIQUID HYDRAZINE AND LIQUID FLUORINE AS A ROCKET PROPELLANT. Sanford Gordon and Vearl N. Huff. July 1953. 83p. diagrs., tabs. (NACA RM E53E12)

Theoretical values of performance parameters for liquid hydrazine and liquid fluorine as a rocket propellant were calculated on the assumption of equilibrium composition during the expansion process for four chamber pressures and a wide range of fuel-oxidant and expansion ratios. The parameters included were specific impulse, combustion-chamber temperature, nozzle-exit temperature, equilibrium composition, mean molecular weight, characteristic velocity, coefficient of thrust, ratio of nozzle-exit area to throat area, specific heat at constant pressure, coefficient of viscosity, and coefficient of thermal conductivity. A correlation is presented for the effect of chamber pressure on several of the parameters. The maximum value of specific impulse was 315.3 pound-seconds per pound for a chamber pressure of 300 pounds per square inch absolute (20.41 atm) and an exit pressure of 1 atmosphere.

NACA RM E53F08

THEORETICAL PERFORMANCE OF MIXTURES OF LIQUID AMMONIA AND HYDRAZINE AS FUEL WITH LIQUID FLUORINE AS OXIDANT FOR ROCKET ENGINES. Sanford Gordon and Vearl N. Huff. July 1953. 43p. diagrs., tabs. (NACA RM E53F08)

Theoretical values of rocket performance parameters for two mixtures of liquid ammonia and hydrazine as fuels with liquid fluorine as oxidant were calculated on the assumption of equilibrium composition during the expansion process for a wide range of fuel-oxidant and expansion ratios. The parameters included were specific impulse, combustion-chamber temperature, nozzle-exit temperature, equilibrium composition, mean molecular weight, characteristic velocity, coefficient of thrust, ratio of nozzle-exit area to throat area, specific heat at constant pressure, coefficient of viscosity, and coefficient of thermal conductivity. Exponents were calculated that permit determination of specific impulse over a range of chamber pressures. The maximum value of specific impulse at sea level for a chamber pressure of 300 pounds per square inch absolute (20.41 atm) was 313.6 pound-seconds per pound for the fuel mixture containing 36.3 percent ammonia by weight and 311.9 pound-seconds per pound for the fuel mixture containing 87 percent ammonia by weight.

NACA RM E53I15

ANALYSIS OF PART-SPEED OPERATION FOR HIGH-PRESSURE-RATIO MULTISTAGE AXIAL-FLOW COMPRESSORS. William A. Benser. December 1953. 41p. diagrs., tab. (NACA RM E53I15)

A multistage axial-flow compressor stage-stacking analysis has indicated that either discontinuities in the performance of inlet stages or stage interactions could result in multiple-valued performance curves at intermediate speeds. The dips exhibited in the surge limits of high-pressure-ratio multistage axial-flow compressors are probably a transition from operation with the inlet stage stalled to operation with the inlet stage unstalled. In addition, the performance curve obtained at a given speed depends on the manner in which speed and throttling are varied in setting that particular operating point. Thus, intermediate-speed surge limits obtained during engine operation of a compressor may be different from those obtained in component testing, and the surge limit obtained during engine acceleration may differ from that obtained during slow decelerations. Severe inlet stage-stall characteristics or stage interactions result in extremely low part-speed efficiencies. Stages with continuous performance characteristics at their stall points, when operated in a multistage compressor, are desirable from the standpoint of good part-speed efficiency and surge-limit characteristics.

NACA RM E54H09

THEORETICAL MAXIMUM PERFORMANCE OF LIQUID FLUORINE - LIQUID OXYGEN MIXTURES WITH JP-4 FUEL AS ROCKET PROPELLANTS. Sanford Gordon and Roger L. Wilkins. October 1954. 18p. diagrs., tabs. (NACA RM E54H09)

Theoretical values of rocket performance parameters were calculated for JP-4 fuel and various mixtures of liquid fluorine and liquid oxygen, assuming both equilibrium and frozen composition during expansion. Data were calculated at several equivalence ratios for each fluorine-oxygen mixture. Parameters included were specific impulse, combustion-chamber temperature, nozzle-exit temperature, equilibrium composition, mean molecular weight, characteristic velocity, coefficient of thrust, and ratio of nozzle-exit area to throat area. Maximum value of specific impulse for chamber pressure of 300 lb/sq in. abs and exit pressure of 1 atm is 299.4 lb-sec/lb for equilibrium composition and 278.9 lb-sec/lb for frozen composition.

NACA RM L50I18

NOTE ON SOME OBSERVED EFFECTS OF ROCKET-MOTOR OPERATION ON THE BASE PRESSURES OF BODIES IN FREE FLIGHT. Paul E. Purser, Joseph G. Thibodaux, and H. Herbert Jackson. November 16, 1950. 28p. diagrs., tabs. (NACA RM L50I18)

Some measurements of the effects of rocket-motor operation on base pressure were obtained incidental to other research on some bodies in free flight. These data are presented and qualitatively analyzed. The analysis indicates that jet effects on drag are of sufficient importance to deserve consideration in the design of jet-motor nozzles, especially for aircraft and missiles where the thrust and drag are of the same order of magnitude. The base-pressure changes induced by the jet should be considered in the structural design of the outer body skin on the aft portion of fuselages containing jets.

NACA RM L50I22

COMPARISON OF LARGE-SCALE FLIGHT MEASUREMENTS OF ZERO-LIFT DRAG AT MACH NUMBERS FROM 0.9 TO 1.7 OF TWO WING-BODY COMBINATIONS HAVING SIMILAR 60° TRIANGULAR WINGS WITH NACA 65A003 SECTIONS. Eugene D. Schult. October 25, 1950. 15p. diagrs., photo., tab. (NACA RM L50I22)

An investigation of zero-lift drag of a fin-stabilized wing-body combination was made at high-subsonic and supersonic speeds in the Reynolds number range of 13×10^6 to 41×10^6. The ratio of body frontal area to wing area was 0.0612. These data are presented with those of a wingless body and similar winged body described in NACA RM L50D26 in which the ratio of body frontal area to wing area was 0.0306. The bodies of both configurations were the same as the wingless body and had parabolic profiles and fineness ratios of 10. The wings were triangular in plan form with a leading-edge sweep of 60° and NACA 65A003 airfoil sections.

#NACA RM L50I26

NACA RM L51I14

FREE-FLIGHT INVESTIGATION TO DETERMINE FORCE AND HINGE-MOMENT CHARACTERISTICS AT ZERO ANGLE OF ATTACK OF A 60° SWEPTBACK HALF-DELTA TIP CONTROL ON A 60° SWEPTBACK DELTA WING AT MACH NUMBERS BETWEEN 0.68 AND 1.44. C. William Martz, James D. Church, and John W. Goslee. December 1951. 36p. diagrs., photos. (NACA RM L51I14)

Control hinge-moment coefficients, normal-force coefficients and chordwise center-of-pressure locations were obtained at zero angle of attack from free-flight tests of two rocket-powered models equipped with 60° sweptback half-delta wing-tip controls mounted on a 60° sweptback delta wing. The data were obtained for deflections up to ±10° over a Mach number range of 0.675 to 1.435 and used to calculate hinge-moment coefficients at various hinge-line locations. Comparisons are made with linearized theory and other rocket-test results.

NACA RM L51I26

EFFECTS ON CONTROL EFFECTIVENESS OF SYSTEMATICALLY VARYING THE SIZE AND LOCATION OF TRAILING-EDGE FLAPS ON A 45° SWEPTBACK WING AT A MACH NUMBER OF 1.9. Carl R. Jacobsen. December 1951. 34p. diagrs., photo., tab. (NACA RM L51I26)

Plain trailing-edge flaps were tested on a 45° sweptback semispan wing in the Langley 9- by 12-inch supersonic blowdown tunnel. The tests were made through an angle-of-attack range of ±6° at a Mach number of 1.9 and a Reynolds number of 2.1×10^6. Flaps having chords and spans which were systematically varied were tested at several spanwise locations. The results were compared with similar results obtained from a related unswept wing. The wing model had an aspect ratio of 2.5, a taper ratio of 0.625, and 6-percent-chord-thick modified hexagonal airfoil sections. Experimental effectiveness parameters are compared with effectiveness parameters calculated by linearized theory.

NACA RM L53I08

AERODYNAMIC CHARACTERISTICS OF A 68.4° DELTA WING AT MACH NUMBERS OF 1.6 AND 1.9 OVER A WIDE REYNOLDS NUMBER RANGE. John E. Hatch, Jr., and James J. Gallagher. November 1953. 44p. diagrs., photos., tabs. (NACA RM L53I08)

The effect of Reynolds number on the aerodynamic characteristics of a 68.4° delta wing is presented. At Mach number 1.62 pressure data are shown for a Reynolds number range of 2.2×10^6 to 7.4×10^6. Force data are presented at a Mach number 1.9 for a Reynolds number range of 7.4×10^6 to 18.4×10^6, and pressure data are given for a range of 2.2×10^6 to 18.4×10^6. Basic studies of the flow in the wing boundary layer and of the flow just outside of the boundary layer are also presented.

NACA RM L53I10

FLIGHT TEST RESULTS OF ROCKET-PROPELLED BUFFET-RESEARCH MODELS HAVING 45° SWEPTBACK WINGS AND 45° SWEPTBACK TAILS LOCATED IN THE WING CHORD PLANE. Homer P. Mason. October 1953. 26p. diagrs., photos., tab. (NACA RM L53I10)

Results of flight tests of two rocket-propelled buffet-research models having 45° sweptback tails located in the chord plane of 45° sweptback wings and of one similar model with no horizontal-tail surfaces are presented as incremental accelerations due to buffeting, trim angles of attack and force coefficients, wing-tip helix angles, static-directional-stability derivatives, and drag coefficients plotted against Mach number.

#NACA RM L53I22c

NACA RM L53I25

SOME EFFECTS OF LEADING-EDGE ROUGHNESS ON THE AILERON EFFECTIVENESS AND DRAG OF A THIN RECTANGULAR WING EMPLOYING A FULL-SPAN PLAIN AILERON AT MACH NUMBERS FROM 0.6 TO 1.5. Roland D. English. November 1953. 16p. diagrs., photos. (NACA RM L53I25)

An investigation has been made of some effects of leading-edge roughness on the rolling effectiveness and drag of an unswept, untapered, 6-percent-thick, circular-arc-airfoil wing. The results indicate that the addition of roughness reduces the rolling effectiveness at subsonic speeds, but has little effect in the supersonic range. Adding roughness increased the drag coefficient over the entire Mach number range from 0.6 to 1.5.

NACA RM L53I28

A FLIGHT INVESTIGATION OF THE EFFECTS OF INCLINATION OF THE PRINCIPAL AXIS OF INERTIA ON THE DYNAMIC LATERAL STABILITY OF THE REPUBLIC XF-91 AIRPLANE. Thomas W. Finch. July 1954. 19p. diagrs., photos., tab. (NACA RM L53I28)

A flight investigation has been conducted to determine the effect of variable wing incidence angle on the dynamic lateral stability of the Republic XF-91 airplane. The tests were conducted over a Mach number range of 0.3 to 0.9 at altitudes of 10,000, 20.000, 30,000, and 37,500 feet at wing incidence angles of -2°, 2°, 4°, and 5.65°.

NACA RM L53I28a

AERODYNAMIC CHARACTERISTICS OF A CANARD-BALANCED, FREE-FLOATING, ALL-MOVABLE STABILIZER AS OBTAINED FROM ROCKET-POWERED-MODEL FLIGHT TESTS AND LOW-SPEED WIND-TUNNEL TESTS. William N. Gardner. December 1953. 65p. diagrs., photos., tabs. (NACA RM L53I28a)

Low-speed wind-tunnel tests and flight tests of two rocket-powered models were conducted on a tail-alone configuration incorporating a canard-balanced free-floating all-movable delta-surface horizontal tail mounted on the tip of a swept vertical tail. The canard-type servoplane is used to change the trim deflection of the free-floating tail, and a linked trailing-edge flap is used to allow the tail to provide a static-stability contribution to a configuration on which it is employed. Data were obtained on the servoplane effectiveness as well as the floating characteristics, dynamic stability, hinge moments, lift, and trim of the all-movable tail over a Mach number range from 0.6 to 1.46 corresponding to Reynolds numbers of 4×10^6 to 10×10^6.

NACA RM L53I29

RESULTS OF A ROCKET-MODEL INVESTIGATION OF CONTROL-SURFACE BUZZ AND FLUTTER ON A 4-PERCENT-THICK UNSWEPT WING AND ON 6-, 9-, AND 12-PERCENT-THICK SWEPT WINGS AT TRANSONIC SPEEDS. Allen B. Henning. November 1953. 33p. diagrs., photos., tabs. (NACA RM L53I29)

The results of an investigation of control-surface buzz and flutter on four rocket-powered models having a 4-percent-thick unswept wing and 6-, 9-, and 12-percent-thick 35° swept wings with free floating and statically mass-balanced control surfaces are presented. All control surfaces buzzed. Buzz was related to presence of shock wave. Amplitude and frequency of the control-surface motion and wing drag were measured.

NACA RM L54I08

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE PRESSURE DISTRIBUTIONS ON A 45° SWEPTBACK VERTICAL TAIL IN SIDESLIP WITH A 45° SWEPTBACK HORIZONTAL TAIL MOUNTED AT 50-PERCENT AND 100-PERCENT VERTICAL-TAIL SPAN. Harleth G. Wiley and William C. Moseley, Jr. November 1954. 89p. diagrs., photos., tabs. (NACA RM L54I08)

This paper presents the results of an investigation in the Langley 7- by 10-foot tunnel to determine the aerodynamic loadings at high subsonic speeds on a 45° sweptback, untapered vertical tail in sideslip. The vertical tail was tested in the presence of a cylindrical body with a 45° sweptback untapered horizontal tail located either at the midspan or tip of the vertical tail. The vertical and horizontal tails had NACA 65A010 airfoil sections perpendicular to the leading edge and aspect ratios of 2.0 and 4.0, respectively. The tests were made at angles of attack of 0°, 4°, and 12° through an angle of sideslip range of -2° to 23° and a Mach number range of 0.60 to 0.95.

NACA RM L54I09

EFFECT OF A WING LEADING-EDGE FLAP AND CHORD-EXTENSION ON THE HIGH SUBSONIC CONTROL CHARACTERISTICS OF A SPOILER-SLOT-DEFLECTOR CONTROL LOCATED AT TWO SPANWISE POSITIONS. Robert F. Thompson and Robert T. Taylor. November 1954. 73p. diagrs., photo., tabs. (NACA RM L54I09)

Incremental force and moment coefficients due to control projection are presented for a wind-tunnel investigation at high subsonic speeds and angles of attack up to 24° to determine the effects of a wing leading-edge modification on the control characteristics of a spoiler-slot-deflector-type control located at two spanwise positions. A few comparative tests were made with the spoiler part of the control used as a plain, flap-type spoiler. The wing was modified by a leading-edge chord-extension over the outboard 35 percent of the semispan in combination with a full-span leading-edge flap deflected 6°. The wing-fuselage model tested had a wing of aspect ratio 4, taper ratio 0.3, 45° sweepback, and NACA 65A006 airfoil sections.

NACA RM L54I13

COMPARISON OF LOW-SPEED ROTOR AND CASCADE PERFORMANCE FOR MEDIUM-CAMBER NACA 65-(C_{l_o} A_{10})10 COMPRESSOR-BLADE SECTIONS OVER A WIDE RANGE OF ROTOR BLADE-SETTING ANGLES AT SOLIDITIES OF 1.0 AND 0.5. George C. Ashby, Jr. December 1954. 40p. diagrs., photo. (NACA RM L54I13)

A medium-camber compressor rotor having NACA 65-($C_{l_o}A_{10}$)10 blades was tested in a low-speed 28-inch test blower. The tests were made at solidities of 1.0 and 0.5 without guide vanes or stators over a wide range of blade-setting angles and quantity flow rates. The measured overall and blade-element performance was compared with the performance estimated from cascade data to extend the correlation of cascade and compressor-rotor data over a broad range of blade-setting angles.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1263

INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF A MODEL WING-PROPELLER COMBINATION AND OF THE WING AND PROPELLER SEPARATELY AT ANGLES OF ATTACK UP TO 90°. Richard E. Kuhn and John W. Draper. 1956. ii, 40p. diagrs., photos., tab. (NACA Rept. 1263. Supersedes TN 3304)

Results are presented of a wind-tunnel investigation of the effects of slipstream for two large-diameter propellers on the aerodynamic characteristics of a wing model. The investigation covered angles of attack from -10° to 90° and thrust coefficients representing free-stream velocities from zero to the normal range of cruising flight. An appreciable increase in the angle of attack for maximum lift with increasing power is indicated. A modification of the method of Smelt and Davies for estimating the effects of slipstreams on the lift-curve slope is presented. Performance calculations for an assumed vertical take-off airplane are also included. Forces and moments on the wing-propeller combination and on the wing and propellers separately are included. A large nose-up pitching moment on the propeller itself was found at high angles of attack.

NACA TN 3576

FURTHER MEASUREMENTS OF INTENSITY, SCALE, AND SPECTRA OF TURBULENCE IN A SUBSONIC JET. James C. Laurence and Truman M. Stickney. October 1956. 24p. diagrs. (NACA TN 3576)

As an extension to the data reported in Technical Note 3561, hot-wire anemometer measurements of the intensity, scale, and spectra of turbulence in a 3.5-in.-diameter free subsonic jet were made for downstream distances from 8 to 20 jet diameters. Eddy size increased with distance from the jet nozzle until a maximum was reached. The position of this maximum depended upon the distance from the jet centerline. After reaching the maximum, the eddy decreased uniformly in size with distance from the nozzle. The nondimensional mean-velocity profiles were nearly similar in a region from 12 to 20 jet diameters from the nozzle. Corresponding similarity in intensity of turbulence profiles, however, was not observed as far as 20 jet diameters downstream of the nozzle.

NACA TN 3683

MECHANISM OF GENERATION OF PRESSURE WAVES AT FLAME FRONTS. Boa-Teh Chu, Johns Hopkins University. October 1956. 20p. diagrs. (NACA TN 3683)

A study has been made of the pressure waves generated at a flame front. An analysis is included of the performance of a flame front and an equivalent heater in producing the pressure waves.

NACA TN 3684

LARGE DEFLECTION OF CURVED PLATES. H. G. Lew, J. A. Fox, and T. T. Loo, Pennsylvania State University. October 1956. 38p. diagrs., tabs. (NACA TN 3684)

Several problems on large deflections of curved plates with compound curvature are treated. Large-deflection equations of plates and cylinders are used. Initial curvature of a plate under axial compression increases its deflection considerably upon application of load. The average shear strain for a plate under shear loading is not much affected by the initial curvature, at least for the initial deflection function used. In addition, for the circular cylindrical plate with small initial curvature under axial compression, the deflections of the plate are affected more by changes in the radius R_0 than by changes in the initial curvature. It is shown that the effective width of the curved plates in longitudinal compression is reduced by the presence of an initial deflection function.

NACA TN 3741

AN INVESTIGATION OF THE LOADS ON THE VERTICAL TAIL OF A JET-BOMBER AIRPLANE RESULTING FROM FLIGHT THROUGH ROUGH AIR. Jack Funk and Richard H. Rhyne. October 1956. 36p. diagrs., tabs. (NACA TN 3741)

Vertical-tail loads were measured in turbulent air on a four-engine jet bomber. Results showed large load oscillations which were lightly damped. Comparison of experimental results with discrete-load calculations indicated that discrete-gust calculations underestimated the loads by 30 to 40 percent and gave

no indication of the low damping. Power spectral analysis, on the other hand, indicated the general frequency characteristics and gave a somewhat better estimate of the peak-load distributions. The present results strongly suggest that discrete-gust calculations for gust loads on vertical tails may seriously underestimate the gust loads for airplanes having lightly damped lateral oscillations.

NACA TN 3747

EQUATIONS AND PROCEDURES FOR NUMERICALLY CALCULATING THE AERODYNAMIC CHARACTERISTICS OF LIFTING ROTORS. Alfred Gessow. October 1956. 21p. diagr., tab. (NACA TN 3747)

Equations and procedures are presented for numerically determining the aerodynamic characteristics of lifting rotors. The equations are general and can account for stall and compressibility effects, as well as variations in hub and blade configurations, that are normally omitted from conventional analytical rotor treatments. The application of the method to solution by automatic computing machines is discussed.

NACA TN 3748

CALCULATION AND COMPILATION OF THE UNSTEADY-LIFT FUNCTIONS FOR A RIGID WING SUBJECTED TO SINUSOIDAL GUSTS AND TO SINUSOIDAL SINKING OSCILLATIONS. Joseph A. Drischler. October 1956. 59p. diagrs., tab. (NACA TN 3748)

The total lift responses to sinusoidal sinking oscillations and to sinusoidal gusts have been calculated, largely from existing information, for wings of various plan forms in subsonic and supersonic flow. For most of the cases considered, closed-form expressions are given and the final results are presented in the form of plots of the square of the modulus of the lift coefficient for wings in a sinusoidally oscillating gust field and in the form of the real and imaginary parts of the lift coefficient for wings undergoing sinusoidal sinking oscillations.

NACA TN 3749

TORSIONAL STIFFNESS OF THIN-WALLED SHELLS HAVING REINFORCING CORES AND RECTANGULAR, TRIANGULAR, OR DIAMOND CROSS SECTION. Harvey G. McComb, Jr. October 1956. 35p. diagrs. (NACA TN 3749)

A theoretical investigation is presented of the torsional stiffness of thin-walled aerodynamic surfaces filled with cores which stabilize the skins. Rectangular, slender triangular, and slender diamond cross sections are considered. Results for the torsional stiffness constants are shown graphically.

NACA TN 3750

AN ANALYSIS OF AIRSPEED, ALTITUDE, AND ACCELERATION DATA OBTAINED FROM A TWIN-ENGINE TRANSPORT AIRPLANE OPERATED OVER A FEEDER-LINE ROUTE IN THE ROCKY MOUNTAINS. Martin R. Copp and Mary W. Fetner. October 1956. 23p. diagrs., tabs. (NACA TN 3750)

Time-history data of airspeed, altitude, and acceleration obtained with the NACA VGH recorder from a twin-engine airplane operated by a regional feeder airline in the Rocky Mountains are evaluated to determine the magnitude and frequency of occurrence of gusts and gust accelerations and the operating airspeeds and altitudes. The results obtained are compared with the results previously obtained from a representative short-haul and long-haul operation.

NACA TN 3754

A SIMPLE METHOD FOR CALCULATING THE CHARACTERISTICS OF THE DUTCH ROLL MOTION OF AN AIRPLANE. Bernard B. Klawans. October 1956. 16p. diagrs., tabs. (NACA TN 3754)

A simple method for calculating the characteristics of the Dutch roll motion of an airplane is obtained by arranging the lateral equations of motion in such form and order that an iterative process is quickly convergent.

NACA TN 3758

INTERACTION OF BEARING AND TENSILE LOADS ON CREEP PROPERTIES OF JOINTS. E. G. Bodine, R. L. Carlson, and G. K. Manning. Battelle Memorial Institute. October 1956. 23p. diagrs., photo. (NACA TN 3758)

The interaction of bearing and tensile loads on the creep behavior of joints was studied. A specimen was designed for this study which possessed some of the general features of pin and rivet joint connections and an apparatus was constructed to apply both bearing and tensile loads to the joint model. Deformation measurements were made by use of a photogrid printed on the joint model.

NACA TN 3763

NEAR NOISE FIELD OF A JET-ENGINE EXHAUST. I - SOUND PRESSURES. Walton L. Howes and Harold R. Mull. October 1956. 51p. diagrs., photos. (NACA TN 3763)

Experimental data without afterburning from a 10,000-pound-thrust turbojet engine are presented in a series of contour maps of overall and 1/3-octave-band sound-pressure levels. Some data on sound-pressure levels were also obtained as a function of jet velocity, at the surface of a stiff plate, and with afterburning. On a dimensionless basis, the apparent locations of acoustical sources as a function of frequency were found to be similar to those indicated by turbulence measurements in a small cold-air jet.

NACA TN 3766

RADIATION AND RECOVERY CORRECTIONS AND TIME CONSTANTS OF SEVERAL CHROMEL-ALUMEL THERMOCOUPLE PROBES IN HIGH-TEMPERATURE, HIGH-VELOCITY GAS STREAMS. George E. Glawe, Frederick S. Simmons, and Truman M. Stickney. October 1956. 25p. diagrs., photo., tabs. (NACA TN 3766)

Radiation and recovery corrections and time constants were experimentally determined for several designs of shielded and unshielded thermocouple probes using chromel-alumel wire. Radiation and time constant data were obtained for Mach numbers from 0.3 to 0.9, static pressure from $\frac{2}{3}$ to $1\frac{1}{3}$ atmospheres, and temperatures from 1500° to 2500° R. Recovery data were obtained for Mach numbers from 0.2 to 0.9 and total pressures from $\frac{1}{7}$ to $1\frac{2}{3}$ atmospheres, at room total temperature. A review of the theory of gas temperature measurements and an analysis of the data show that simple empirical formulas may be used to correlate corrections for various gas-stream conditions.

NACA TN 3768

ON POSSIBLE SIMILARITY SOLUTIONS FOR THREE-DIMENSIONAL INCOMPRESSIBLE LAMINAR BOUNDARY LAYERS. I - SIMILARITY WITH RESPECT TO STATIONARY RECTANGULAR COORDINATES. Arthur G. Hansen and Howard Z. Herzig. October 1956. 30p. tab. (NACA TN 3768)

Solutions of mainstream flow patterns for all possible incompressible laminar-boundary-layer flows having classical similarity with respect to rectangular-coordinate systems are derived. These solutions, which apply to a wide range of flows, are summarized in table form.

NACA TN 3770

IMPINGEMENT OF DROPLETS IN 60° ELBOWS WITH POTENTIAL FLOW. Paul T. Hacker, Paul G. Saper, and Charles F. Kadow. October 1956. 54p. diagrs., tabs. (NACA TN 3770)

Theoretical trajectories were determined for droplets in air flowing through 60° elbows. The elbows were established by selecting as walls of each elbow two streamlines of a two-dimensional flow field produced by a complex potential function. These elbows are suitable for use in aircraft air-inlet ducts. Droplet impingement data are presented in terms of dimensionless parameters along with empirical equations so that the results can be applied over a wide range of conditions and elbow sizes. A comparison of the 60° elbow with previous calculations for a comparable 90° elbow indicated that the impingement characteristics of the two elbows are very similar.

NACA TN 3771

LOW-SPEED WAKE CHARACTERISTICS OF TWO-DIMENSIONAL CASCADE AND ISOLATED AIRFOIL SECTIONS. Seymour Lieblein and William H. Roudebush. October 1956. 49p. diagrs., tabs. (NACA TN 3771)

Available low-speed wake data of two-dimensional cascade and isolated airfoil sections are analyzed to determine empirical and theoretical variations with downstream distance of such wake properties as minimum velocity, form factor, momentum thickness, full thickness, total-pressure loss, and ratio of mass-averaged to area-averaged loss. The reenergizing of the wake downstream of the blade is shown to occur very rapidly, with most of the mixing loss and changes in wake characteristics taking place within $\frac{1}{4}$ to $\frac{1}{2}$ chord length behind the blade. Except for the variation of momentum thickness, the developments of the wake behind the cascade airfoil and the isolated airfoil are generally similar.

NACA TN 3776

HEAT-TRANSFER MEASUREMENTS ON TWO BODIES OF REVOLUTION AT A MACH NUMBER OF 3.12. John R. Jack and N. S. Diaconis. October 1956. 36p. diagrs., photos., tabs. (NACA TN 3776)

Heat-transfer rates were measured on a cone cylinder and a parabolic-nosed cylinder at Reynolds numbers up to 12×10^6 based on model length for heated and cooled surfaces. The experimental data were obtained with an axial temperature distribution and then corrected to the isothermal case. The laminar data agreed closely with theory at all temperature levels.

NACA TN 3777

SEAT DESIGN FOR CRASH WORTHINESS. I. Irving Pinkel and Edmund G. Rosenberg. October 1956. 42p. diagrs., photos., tab. (NACA TN 3777)

On the basis of deceleration data obtained in full-scale crashes, a description of crash deceleration pulses is presented which is suitable for seat design. Charts are presented for obtaining the maximum deceleration loads experienced by the seat and passenger in response to their crash deceleration pulses. Finally, a method is presented for determining the seat strength, spring stiffness, and deformation beyond the elastic limit required to serve in a crash deceleration pulse of given description. Measurement of passenger decelerations in full-scale laboratory and crash studies shows that the general principles presented in the report apply.

NACA TN 3787

HEAT-CAPACITY MEASUREMENTS OF TITANIUM AND OF A HYDRIDE OF TITANIUM FOR TEMPERATURES FROM 4° TO 15° K INCLUDING A DETAILED DESCRIPTION OF A SPECIAL ADIABATIC SPECIFIC-HEAT CALORIMETER. M. H. Aven, R. S. Craig, and W. E. Wallace, University of Pittsburgh. October 1956. 30p. diagrs., tabs. (NACA TN 3787)

Results of heat-capacity measurements on samples of pure titanium and of a hydride of titanium are presented and compared with calculated results. The measurements were made using a special adiabatic specific-heat calorimeter which is described in detail.

NACA TN 3792

A THEORETICAL ANALYSIS OF HEAT TRANSFER IN REGIONS OF SEPARATED FLOW. Dean R. Chapman. October 1956. 47p. diagrs., tabs. (NACA TN 3792)

An analysis is made of the rate of heat transfer to regions of separated flow in compressible streams. The physical mechanism postulated applies in principle to both laminar and turbulent flow, and to conditions where gas is injected into a separated region. Under the special condition of zero boundary-layer thickness at the separation point, the analysis yields relatively simple equations. Detailed calculations are presented for laminar separations in compressible flow with Prandtl numbers between 0.1 and 10.0.

NACA TN 3793

EXPLORATORY INVESTIGATION OF THE USE OF AREA SUCTION TO ELIMINATE AIR-FLOW SEPARATION IN DIFFUSERS HAVING LARGE EXPANSION ANGLES. Curt A. Holzhauser and Leo P. Hall. October 1956. 18p. diagrs. (NACA TN 3793)

Tests were made at a mean inlet Mach number of 0.2 with area suction applied to conical diffusers with expansion angles of 30° and 50° and exit to inlet area ratios of 2. Air-flow separation was eliminated with suction mass flows of 3 and 4 percent of the inlet mass flows for the 30° and 50° diffusers, respectively.

NACA TN 3799

AN AIR-FLOW-DIRECTION PICKUP SUITABLE FOR TELEMETERING USE ON PILOTLESS AIRCRAFT. Wallace L. Ikard. October 1956. 25p. diagrs., photos. (NACA TN 3799. Supersedes RM L53K16)

A vane-type air-flow-direction pickup is described which is suitable for telemetering angle-of-attack and angle-of-sideslip data from rocket-propelled pilotless aircraft models. Test results which are presented show that the device performs well under high accelerations and is stable throughout a Mach number range from subsonic to above a Mach number of 2.5.

NACA TN 3802

INVESTIGATION OF A RELATED SERIES OF TURBINE-BLADE PROFILES IN CASCADE. James C. Dunavant and John R. Erwin. October 1956. 100p. diagrs. (NACA TN 3802. Supersedes RM L53G15)

Series of directly related turbine blade shapes uniformly variable in camber are designed to satisfy the usual turbine-blade operating requirements of inlet air angle and turning angle. Low-speed cascade test results of five blade sections and sample high-speed cascade tests for two blade sections of these series are presented. A method of properly cambering turbine blade shapes based on low-speed test results is given.

NACA TN 3804

A FACTOR AFFECTING TRANSONIC LEADING-EDGE FLOW SEPARATION. George P. Wood and Paul B. Gooderum. October 1956. 43p. diagrs., photos. (NACA TN 3804)

A change in flow pattern that was observed as the free-stream Mach number was increased in the vicinity of 0.8 was described in NACA Technical Note 1211 by Lindsey, Daley, and Humphreys. The flow on the upper surface behind the leading edge of an airfoil at an angle of attack changed abruptly from detached flow with an extensive region of separation to attached supersonic flow terminated by a shock wave. In the present paper, the consequences of shock-wave—boundary-layer interaction are proposed as a factor that may be important in determining the conditions under which the change in flow pattern occurs. Some experimental evidence in support of the importance of this factor is presented.

NACA TN 3807

CONVERSION OF INVISCID NORMAL-FORCE COEFFICIENTS IN HELIUM TO EQUIVALENT COEFFICIENTS IN AIR FOR SIMPLE SHAPES AT HYPERSONIC SPEEDS. James N. Mueller. October 1956. 31p. diagrs. (NACA TN 3807)

A correlation factor applicable for converting inviscid aerodynamic normal-force coefficients of simple shapes in helium to equivalent coefficients in air is found by using calculations based on the shock-expansion method at Mach numbers of 12, 16, and 20.

NACA TN 3810

CHARTS FOR ESTIMATING THE HOVERING ENDURANCE OF A HELICOPTER. Robert A. Makofski. October 1956. 15p. diagrs. (NACA TN 3810)

As a means of comparing the performance capabilities of various helicopter propulsion systems, charts have been presented for estimating the hovering endurance of a helicopter in the form of a hovering-endurance parameter as a function of the ratio of total fuel load to helicopter initial weight for a range of initial thrust coefficients from 0.002 to 0.012 and for values of rotor mean lift coefficient from 0.24 to 0.72. The charts were presented for a helicopter

having rotor blades with ideal twist. However, corrections may be applied to the hovering endurance to account for other combinations of twist and taper. The effects of stall and compressibility have been neglected.

NACA TN 3811

CHARTS ADAPTED FROM VAN DRIEST'S TURBULENT FLAT-PLATE THEORY FOR DETERMINING VALUES OF TURBULENT AERODYNAMIC FRICTION AND HEAT-TRANSFER COEFFICIENTS. Dorothy B. Lee and Maxime A. Faget. October 1956. 16p. diagrs., tab. (NACA TN 3811)

A modified method of Van Driest's flat-plate theory for turbulent boundary layer has been found to simplify the calculation of local skin-friction coefficients which, in turn, have made it possible to obtain through Reynolds analogy theoretical turbulent heat-transfer coefficients in the form of Stanton number. A general formula is given and charts are presented from which the modified method can be solved for Mach numbers 1.0 to 12.0, temperature ratios 0.2 to 6.0, and Reynolds numbers 0.2×10^6 to 200×10^6.

NACA TN 3812

FLIGHT INVESTIGATION OF THE STABILITY AND CONTROL CHARACTERISTICS OF A VERTICALLY RISING AIRPLANE RESEARCH MODEL WITH SWEPT OR UNSWEPT WINGS AND ×- OR +-TAILS. Robert H. Kirby. October 1956. 30p. diagrs., photos. (NACA TN 3812)

The take-off, landing, hovering, and transition flight characteristics of a propeller-driven, fighter-type, vertically rising airplane model were obtained from time histories of the flights and from the pilots' opinions of the flight characteristics. In general, there were no major differences in the behavior of any of the configurations, all of which performed satisfactorily.

NACA TN 3816

STATIC STRENGTH OF ALUMINUM-ALLOY SPECIMENS CONTAINING FATIGUE CRACKS. Arthur J. McEvily, Jr., Walter Illg, and Herbert F. Hardrath. October 1956. 54p. diagrs., photos., tabs. (NACA TN 3816. Supersedes RM L55D15a)

Seven configurations of specimens made of 2024 and 7075 aluminum-alloys in both rolled and extruded form were subjected to repeated axial loads until fatigue cracks of various lengths were formed. The specimens were then subjected to static tests to determine the residual static strength. Small cracks resulted in disproportionately large reductions of static strength, the reduction being greater for 7075 than for 2024 aluminum alloy. A simple method of analysis which predicts the observed results was developed and described.

NACA TN 3829

EFFECT OF PRESSURE ON THE SPONTANEOUS IGNITION TEMPERATURE OF LIQUID FUELS. Cleveland O'Neal, Jr. October 1956. 21p. diagrs., tabs. (NACA TN 3829)

Spontaneous ignition temperatures were measured in air for n-heptane, isooctane, benzene, and JP-4 and JP-5 aviation fuels in the pressure range of 1 to 9 atmospheres. A solid stream (no spray) of fuel was injected into a 125-cc Erlenmeyer flask enclosed in a bomb. Fuel charges were varied so that the lowest temperature at which spontaneous ignition occurs was obtained. The spontaneous ignition temperature of all the fuels decreased with increasing pressure. Most of the decrease occurred in the range of 1 to 3 or 4 atmospheres. Time lags before ignition were measured.

NACA TN 3831

TABULATION OF MASS-FLOW PARAMETERS FOR USE IN DESIGN OF TURBOMACHINE BLADE ROWS FOR RATIOS OF SPECIFIC HEATS OF 1.3 AND 1.4. Warren J. Whitney. October 1956. 111p. diagrs., tabs. (NACA TN 3831)

Mass-flow tables are presented that enable a quick and accurate determination of the integrated average specific mass flow across a region where the end-point velocities are known, commensurate with the assumptions that the total state is constant and the static pressure varies linearly between the two velocities. The tables include specific-mass-flow parameter and ratio of static to total pressure.

NACA TN 3843

EXPERIMENTAL STEADY-STATE YAWING DERIVATIVES OF A 60° DELTA-WING MODEL AS AFFECTED BY CHANGES IN VERTICAL POSITION OF THE WING AND IN RATIO OF FUSELAGE DIAMETER TO WING SPAN. Byron M. Jaquet and Herman S. Fletcher. October 1956. 20p. diagrs., tab. (NACA TN 3843)

Results are presented of an investigation conducted in the Langley stability tunnel to determine the effects of vertical position of the wing and the effects of the ratio of the fuselage diameter to wing span on the steady-state yawing derivatives of a 60° delta-wing model. The test Mach number was 0.13 and the test Reynolds number was 1.65×10^6.

NACA TN 3858

A LOW-SPEED EXPERIMENTAL INVESTIGATION OF THE EFFECT OF A SANDPAPER TYPE OF ROUGHNESS ON BOUNDARY-LAYER TRANSITION. Albert E. von Doenhoff and Elmer A. Horton. October 1956. 43p. diagrs., photos. (NACA TN 3858)

An investigation conducted in the Langley low-turbulence pressure tunnel at low speeds showed that for sandpaper-type roughness the occurrence of transition could be correlated on the basis of a local roughness Reynolds number based on the size of the roughness and the velocity at the top of the

roughness. The extent of the roughened area does not appear to have an important effect on the critical value of the roughness Reynolds number.

Royal Aircraft Establishment (Gt. Brit.)
SOME MEASUREMENTS OF THE VOLATILITY OF SYNTHETIC LUBRICANTS. D. J. Barke and G. Kinner. June 1956. 14p. diagr., tabs. (RAE Tech. Note Chem. 1282)

Measurements of the volatility of synthetic lubricants are described using three separate methods of test, but only that using the A. S. T. M. evaporation cell is considered to have satisfactory precision. Rate of evaporation from the A. S. T. M. cell is found to be a function of sample size and to be a complex function of rate of transpiration when the latter is less than approximately 2 l./min. Above this figure, the rate of evaporation of various organic liquids is directly proportional to rate of transpiration and to the vapor pressure of the liquid examined. Use of nitrogen, instead of air, reduces the rate of loss in weight by eliminating tendency to oxidation at elevated temperatures. A qualitative explanation of behavior in the A. S. T. M. cell is offered.

Royal Aircraft Establishment (Gt. Brit.)
SOME CREEP PROPERTIES OF AN 18/8 STAINLESS STEEL AT ROOM TEMPERATURE, 250° C, 400° C, AND 550° C. L. W. Larke and R. A. Whittaker. March 1956. 14p. diagrs., tabs. (RAE Tech. Note Met. 240)

Constant load tensile creep tests have been made on resoftened 18/8 type stainless steel to B. S. S. S. 110 at room temperature (22° C), 250° C, 400° C, and 550° C. Stresses, approximating to the 0.05 percent P. S., 0.10 percent P. S., or 0.20 percent P. S., were determined on and applied to individual creep test pieces at each temperature. Two additional tests, demonstrating the effect of 0.1 percent and 1.0 percent prior straining at room temperature, are included in the series creep tested at 250° C. In all cases the creep curves indicate a rapid increase in strain followed by a relatively small creep rate. This behavior is typical of a material which strain hardens under applied stress. The effect of prior strain at room temperature is to reduce markedly the amount of strain on loading. The shapes of the creep curves preclude the more usual types of assessment of properties but, for comparative purposes, Table II, showing variation of strain with time, is included.

Royal Aircraft Establishment (Gt. Brit.)
CALCULATION OF THE SHAPE OF A THIN SLENDER WING FOR A GIVEN LOAD DISTRIBUTION AND PLANFORM. J. H. B. Smith. January 1956. 22p. diagrs. (RAE Tech. Note Aero 2410)

The problem considered in this note is that of finding the camber and twist for a swept wing of specified slender plan form which will produce the same chordwise lift distribution at each spanwise station as in two-dimensional flow past a flat plate, in conjunction with a uniform distribution of chord loading. Linearized inviscid potential flow theory is used and the results are valid only if $A^2|1 - M^2| \ll 1$. The slope of the wing is obtained in closed form as a function of two rectangular coordinates for wings with straight-swept leading and trailing edges and streamwise tips. Numerical results are given for the chordwise and spanwise variations of the slope of the wing surface measured in the chordwise (that is, the streamwise) direction, at several stations; and chordwise wing sections are drawn, for two particular plan forms. These sections are found to have continuous tangents and not more than three discontinuities of curvature. Spanwise distributions of camber and local incidence are given for the two wings.

Royal Aircraft Establishment (Gt. Brit.)
FATIGUE LOADINGS IN FLIGHT: LOADS IN THE WING OF A VARSITY. Anne Burns. May 1956. 23p. diagrs., tabs. (RAE Tech. Note Structures 192)

Data are presented on the number of load cycles of various magnitudes occurring in the wing of a Varsity in normal ground and flight conditions. The conditions include taxiing, take-off, landing, and flight in turbulence. The relative importance of the loads in the different conditions is illustrated by reference to the loads in a typical flight. A relationship is determined between wing loads and accelerations in turbulence so that the test results can, if required, be related to gust data obtained operationally by means of the counting accelerometer.

Royal Aircraft Establishment (Gt. Brit.)
EXPERIMENTAL INVESTIGATION OF THE PRESSURE DISTRIBUTION AT THE CENTRE-SECTION OF A SWEPTBACK WING AT HIGH SUBSONIC SPEEDS. T. E. B. Bateman and A. J. Lawrence. August 1955. 35p. diagrs., photos., tabs. (RAE Aero 2556)

The uncertainty of the validity of theoretical estimates and the absence of experimental data for the pressure distribution at the center section of a sweptback wing at high subsonic speeds led to the present tests. The measurements have been made on a 40° sweptback wing over the Mach number range 0.50 to 0.94, at zero incidence. Given pressures are reached further aft at the center section than on a section of the infinite-sheared wing. In particular the supersonic region, when formed, occurs much farther aft and the shock wave moves quickly to a position close behind the trailing edge. The isobars lose their sweep in the neighborhood of the center

section and this reduces the critical Mach number from 0.88 for the sheared wing to 0.81 for the center section. The maximum local Mach number at the center section tends to a steady value of about 1.15 at high subsonic speeds. Theoretical estimates of the pressure distributions on the sheared wing at zero incidence are shown to agree well with the measured values for speeds at which no shock waves form but estimates for the center section agree well only at very low speeds. At higher speeds (even at $M = 0.5$) the theory predicts too low a pressure over the forward half of the chord and too low a suction over the rear half, that is, it underestimates the "center effect."

NOTES ON THE PRACTICAL APPLICATION OF THE METHOD OF R. A. E. REPORT NO. STRUCTURES 168. D. Williams. May 1956. 49p. diagrs. (RAE Structures 209)

In report No. Structures 168, a method for deriving the influence coefficients of any type of wing, and hence of deriving the deflection and stresses was described in outline. The practical application of the method, however, raises a number of minor problems - mostly concerned with boundary values - which have all to be overcome if the method is to become popular among stressmen. Some of the more important of these problems are treated in this report.

Royal Aircraft Establishment (Gt. Brit.)
LOW SPEED STATIC AND FLUCTUATING PRESSURE DISTRIBUTIONS ON A CYLINDRICAL BODY WITH A SQUARE FLAT PLATE AIRBRAKE. T. B. Owen. January 1956. 18p. diagrs., tab. (RAE Tech. Note Aero 2396)

There is a very rapid increase both in the rms amplitude of the pressure fluctuations and in the area of the body affected, if the brake angle is increased beyond 50°. At the lower frequencies there is a large increase in amplitude between 40° and 50° which is associated with the appearance of a regular shedding of turbulent eddies. On the model used, with an average of about 27 percent of the length of the side of the brake, the shedding frequencies are in close agreement with those measured on an isolated plate at the smaller brake angles and slightly higher than on an isolated plate at the higher brake angles. The fluctuating pressures due to the brake are little affected by the distance of the brake from the tail of the body.

WIND TUNNEL TESTS ON ANTISYMMETRIC FLUTTER OF A DELTA WING WITH ROLLING BODY FREEDOM. D. R. Gaukroger and D. Nixon. 1956. 9p. diagrs. (ARC CP 259)

Wind-tunnel tests on a half-span model to determine the antisymmetric flutter characteristics of a delta wing are described. The model had a leading-edge sweepback of 45° and a tip chord 1/16th of the root chord. The effect of fuselage rolling moment of inertia on critical flutter speed and frequency was investigated. The results show that body freedom flutter is obtained under conditions of fuselage rolling moment of inertia that are representative of full scale, and that the flutter speeds are considerably higher and the frequencies lower than with the root fixed. With large values of fuselage rolling moment of inertia disturbed root flutter occurs, the speeds again being higher than with the root fixed.

ADDITIONAL DATA ON SURFACE SLOPES OF THE RAE 100-104 AEROFOIL SECTIONS. Edna M. Love and J. Williams. 1956. 10p. tabs. (ARC CP 252)

To supplement earlier data, the surface slopes of the RAE 100, 101, and 103 sections are tabulated, and for the RAE 102 and 104 sections additional values are quoted closer to the leading edge than before. An elementary but flexible method of specifying the minimum number of tangent planes needed for airfoil manufacture is also given.

MODELS FOR AERO-ELASTIC INVESTIGATIONS. H. Templeton. (Presented at International Congress on Models in Engineering, Venice, October 1-5, 1955, sponsored by Accademia Nazionale dei Lincei and Società Adriatica di Elettricità). 1956. 22p. diagrs., photos. (ARC CP 255)

An account is given of several types of aeroelastic model used for flutter investigations. The various purposes for which they are used are outlined, and the scale relationships for prediction models are derived. Different types of model construction are described and their main applications are defined. The construction types include flexible skin, segmented airfoil, stressed skin, solid, and semirigid models.

FATIGUE LOADINGS IN FLIGHT: LOADS IN THE TAILPLANE AND FIN OF A VARSITY. Anne Burns. 1956. 20p. diagrs., tabs. (ARC CP 256)

Data are presented on the number of load cycles of various sizes occurring in the tailplane and fin of a Varsity in normal ground and flight conditions. The conditions include flight in turbulence, take-off, landing, taxiing, and ground running of the engines. The relative importance of the loads in the different conditions is illustrated by reference to the loads in a typical flight.

SOME FATIGUE CHARACTERISTICS OF A TWO SPAR LIGHT ALLOY STRUCTURE (METEOR 4 TAILPLANE). K. D. Raithby and Jennifer Longson. 1956. 32p. diagrs., photos., tabs. (ARC CP 258)

Results are given for fatigue tests on 61 Meteor tail planes, treated as representative small-scale wing systems and tested under a variety of loading conditions. The object of the investigation was to study the fatigue characteristics of a typical aircraft structure, in particular the effects of mean load and alternating load on the endurance. The effects of preloading, periodic overloading, and low temperatures were also investigated. Endurance curves are given for different mean loads; the results indicate that, for a given alternating load, the endurance is roughly inversely proportional to mean load. Substantial improvements in endurance may be obtained by preloading and by periodic overloading. The endurance at low temperature is higher than at room temperature.

REPORT OF THE SECOND YEAR'S FLYING ON THE DEVELOPMENT OF FLIGHT TESTING TECHNIQUES FOR FINDING AND MEASURING NATURAL ICING CONDITIONS. G. C. Abel. 1956. 39p. diagrs., photos., tabs. (ARC CP 222)

Icing conditions extending over 100 miles have been found in strato-cumulus clouds over areas from East Anglia to the English Channel. Average liquid-water contents were 0.4-0.5 gms/cubic meter but an exceptional value of 1.4 gms/cubic meter is reported. This advance in sampling technique is being extended to try to measure liquid-water content and total-water content by timing the exposures. The RAE thermal ice detectors have not yet reached their final form but have been improved considerably. The Smiths ice detector has been calibrated to give liquid-water content and together with the rotating disk has continued to be very valuable. Meteorological Office forecasts of icing conditions have continued to be reliable.

THE STRENGTH OF TUBES UNDER UNIFORM EXTERNAL PRESSURE. P. C. Cleaver. 1956. 203p. diagrs., photos., tabs. (ARC CP 253)

This report traces the development of theoretical solutions to the problem of determining the strength of tubes subjected to uniform external pressure, and describes an extensive series of tests to check the accuracy of the Sturm solution to this problem and the effects of material properties on collapse pressure. A total of 530 tests were made covering ranges of length:diameter from 0.0098 to 0.056. The mean collapse pressure of the tests designed to check the accuracy of the Sturm solution corrected for eccentricity effects exceeded the mean theoretical collapse pressure by 2.2 percent, the standard deviation was 7.0 percent, and the distribution approximately Gaussian. It is concluded that this theory may confidently be used to predict the strength of tubes under uniform external pressure applied to the sides only.

AN UNCONVENTIONAL TYPE OF FATIGUE-TESTING MACHINE. F. Aughtie and H. L. Cox. 1955. 12p. diagrs. (ARC R & M 2833; ARC 1880)

The general principles governing the design of fatigue-testing machines are considered, and the operation of a machine in which the range of load is generated by resonant oscillation of a mass on the end of a spring is examined. The advantages attendant upon operation at the resonant speed are demonstrated, and a driving mechanism which insures stable operation at the resonant frequency is described. The construction and operation of a direct-stress fatigue-testing machine embodying the principles of resonant oscillation are described and skeleton designs for a torsional fatigue-testing machine suitable for testing specimens 3 inches in diameter and for a direct-stress-fatigue testing machine to give a range of 50 tons are appended.

A SIMPLIFIED TREATMENT OF A FIXED-ROOT SWEPT WING BUILT ON HILL'S ISOCLINIC PRINCIPLE. D. Williams. 1956. 15p. diagrs., tab. (ARC R & M 2870; ARC 13,945. Supersedes RAE Structures 101)

This note shows how the Hill Aero-isoclinic principle works out in practice for a swept wing, fixed at the root and having straight flexural and inertia axes. The conditions assumed are readily represented in a wind-tunnel model and experiments by Lambourne show good agreement with theory. The further aft the flexural axis from the quarter-chord position, the smaller is the sacrifice of wing torsional stiffness entailed in making a swept wing isoclinic, and previous work has on that account taken a far-aft position as a reasonable basic assumption. It is shown that by sacrifice to torsional stiffness the gap between the two axes may be reduced and one aspect of the constructional problem is simplified.

V-G RECORDS FROM VAMPIRE AIRCRAFT. (MARCH 1951-OCTOBER 1951). E. Marjorie Owen and J. R. Heath-Smith. 1956. 17p. diagrs., photos., tabs. (ARC R & M 2963; ARC 15,143. Supersedes RAE Tech. Note Structures 88)

Four hundred sixty-one V-g records covering 923 flying hours were taken from Vampire aircraft operating in England and Germany during the period March to October 1951. V-g boundaries expected to be exceeded once in 30, 100, and 300 hours are estimated, special consideration being given to aircraft engaged on ground-attack duties. The results confirm the general belief that more severe accelerations and higher speeds may be expected when aircraft are on ground-attack duties than when they are on other duties.

AN EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF DEFORMATION ON THE AERODYNAMIC CHARACTERISTICS OF A SWEPT-BACK WING. Joseph Black. 1956. 34p. diagrs., photos., tabs. (ARC R & M 2938. Supersedes: ARC 16,172; Perf. 1145; S & C 2806)

A wind-tunnel investigation of the effects of structural deformation on the pressure distributions round a tapered wing has been carried out over a range of deformations at a RN of 0.6×10^6. A technique for constructing a model and deforming it into any desired deformation has been successfully developed and described. The cycle can be repeated any number of times with the same model, to cover a range of deformations. From the modes investigated the appropriate deformations required to produce an almost elliptic span loading at a selected moderate overall lift, or to delay tip stalling at high incidence, were established.

EFFECTS OF REYNOLDS NUMBER ON THE FLOW OF AIR THROUGH A CASCADE OF COMPRESSOR BLADES. H. G. Rhoden. 1956. 34p. diagrs., photos. (ARC R & M 2919; ARC 15,259)

The experimental work consisted of the separate testing of three cascades of axial-flow compressor blades of camber angles 20°, 30°, and 40°, respectively. Measurements were made of the distribution of static pressure over the central cross section of the middle blade of each cascade, together with traverses of static pressure, total head, and angle of flow at inlet and outlet to each cascade in the plane of the central cross section. The tests covered a range of actual Reynolds number from 3×10^4 to 5×10^5, based on the inlet air velocity and the blade chord, and also a range of inlet air angle α_1, from 35° to 60°.

THE BUCKLING SHEAR STRESS OF SIMPLY-SUPPORTED, INFINITELY-LONG PLATES WITH TRANSVERSE STIFFENERS. P. W. Kleeman. 1956. 18p. diagrs., tab. (ARC R & M 2971; ARC 15,828. Supersedes RAE Structures 140)

This report is an extension of previous theoretical investigations of the elastic buckling in shear of flat plates reinforced by transverse stiffeners. The plates are treated as infinitely long and simply supported along the long sides. Stiffeners are spaced at regular intervals, dividing the plate into a number of panels of uniform size. The effect of bending and torsional stiffnesses of the stiffeners upon the buckling shear stress is calculated for the complete range of stiffnesses, for panels with ratios of width to stiffener spacing of 1, 2, and 5. The results are presented in tabular and graphical form.

A WIND-TUNNEL TECHNIQUE FOR FLUTTER INVESTIGATIONS ON SWEPT WINGS WITH BODY FREEDOMS. P. F. Jordan and F. Smith. 1955. 11p. diagrs., photos. (ARC R & M 2893; ARC 13,729. Supersedes RAE Structures 73)

The practice of ignoring the body freedoms of aircraft in making wing-flutter investigations is no longer justified for modern designs with swept wings and especially for tailless aircraft. A technique is described which has been developed for wind-tunnel tests on wing-flutter models with the body freedoms. A half-span wing model is used, attached to a rigid body; longitudinal stability is insured, and the body-mass parameters are reduced to small values, by an appropriate arrangement of supporting springs. The ease of parameter variations makes the wind-tunnel rig suitable for systematic investigation.

THE SUBSONIC FLOW PAST SWEPT WINGS AT ZERO LIFT WITHOUT AND WITH BODY.
D. Küchemann and J. Weber. 1956. 65p. diagrs., tabs. (ARC R & M 2908)

A review is given of the effects associated with the subsonic inviscid flow past swept wings at zero lift with the aim of providing the information needed for an understanding of the flow phenomena. Methods of obtaining the full benefit of sweep are described. Detailed solutions for incompressible flow are given for three basic cases: (a) the sheared wing of infinite span, (b) the center section of a swept wing of infinite span, and (c) the flow in the curved intersection line between wing and body. These solutions are used to find approximate solutions for any given wing of finite aspect ratio. The Prandtl-Glauert procedure is extended and applied to derive approximations for the compressible flow in the subcritical region. The special cases treated in detail are: the flow in the tip regions of wings; tapered wings; wing-fuselage interference for symmetrical arrangements; and modifications to the wing or to the body shape, for instance to restore sheared-wing conditions.

PRESSURE AND BOUNDARY-LAYER MEASUREMENTS ON A TWO-DIMENSIONAL WING AT LOW SPEED. G. G. Brebner and J. A. Bagley. 1956. 47p. diagrs., tabs. (ARC R & M 2886; ARC 15,083. Supersedes RAE Aero 2455)

Results are given of pressure measurements and boundary-layer traverses on a two-dimensional wing with 10 percent RAE 101 section at RN of 1.6×10^6 and 3.2×10^6. The results, which have been integrated to give lift, drag, and aerodynamic-center characteristics, are used to check some calculation methods for the growth of the turbulent boundary layer and for the effect of a known boundary layer on the pressure distribution. The calculation of the boundary layer still needs a little refinement before it is accurate enough to predict viscosity effects on pressure distribution, lift, drag, and aerodynamic center; but these effects can be calculated if the actual boundary-layer characteristics are known.

SOME FLUTTER TESTS ON SWEPT-BACK WINGS USING GROUND-LAUNCHED ROCKETS. W. G. Molyneux and F. Ruddlesden. 1956. 16p. diagrs., tabs. (ARC R & M 2949; ARC 16,551. Supersedes RAE Structures 155)

This report gives the results of tests on flutter models of untapered wings with 20°, 40°, and 60° sweepback. Tests have been made up to a M = 1.4. A comparison is made between the measured flutter speeds and the speeds estimated using a flutter speed formula. Modifications to the formula are proposed which include a compressibility correction. A comparison is made between measured flutter speeds and those calculated using two-dimensional incompressible flow theory. This shows that the calculated speeds are lower than the measured speeds except in the transonic region, where they are in some cases slightly higher. The calculated flutter frequencies are on the average some 20 percent higher than the measured values.

Aeronautical Research Council (Gt. Brit.)
WIND-TUNNEL OBSERVATIONS OF BOUNDARY-LAYER TRANSITION ON A WING AT VARIOUS ANGLES OF SWEEPBACK. A. Anscombe and L. N. Illingworth. 1956. 9p. diagrs., photos., tabs. (ARC R & M 2968; ARC 15,019. Supersedes RAE Tech. Note Aero 2170)

Visual observations have been made of boundary-layer transition on a wind-tunnel model of constant chord at zero to 50°. At each angle above 25° a critical speed could be found within the speed range of the tunnel (400 ft/sec) at which striations appeared within the laminar boundary layer, while the transition line itself lay at 50 percent to 60 percent chord. As the speed was further increased transition started to move forward, finally occurring close to the leading edge. The wind speed at which the striations appeared and the forward movement of transitions started, decreased with increasing angle of sweepback.

University of Oklahoma Research Institute. FLAME STABILIZATION IN GASES FLOWING CYCLONICALLY: FLOW CHARACTERISTICS, TEMPERATURE, GAS ANALYSES. Lyle F. Albright and Lloyd G. Alexander. (Final rept. for period September 1954 to September 1955). viii, 104p. diagrs., photos., tabs. (Oklahoma U. Research Inst.)

Flow measurements were made in this investigation of a stable flame in an emergent cyclonic free jet. Flames were stabilized in 2-inch I. D. ducts over a wide range of flow conditions. Flow characteristics, temperatures, and gas analyses were determined for several typical flames in a duct. The flow characteristics of cyclonic air in a duct were established. Stability limits were measured for a cyclonic flame in a diverging section. The rates of energy release were calculated for several cyclonic flames, and they were found to be high as compared to other types of flames.

THE EFFECTS OF TIP-MOUNTED JET NACELLES ON THE TRANSONIC CHARACTERISTICS OF LOW-ASPECT-RATIO WINGS. Charles F. Coe. December 1952. 81p. diagrs., photos., tabs. (NACA RM A52J21)

An investigation has been conducted to determine the effects of tip-mounted jet-engine nacelles on the aerodynamic characteristics of low-aspect-ratio rectangular wings of varying aspect ratio, camber, and thickness. Nacelles were mounted in three positions in a vertical plane at the tip. Data are also presented for a tapered wing with and without a nacelle mounted symmetrically at the tip. The test Mach number was varied from 0.60 to 1.12 which corresponded to a test Reynolds number range of 1.6 million to 2.1 million for the rectangular wings and 2.3 million to 3.1 million for the tapered wing.

NACA RM A53J26

THE USE OF A LEADING-EDGE AREA-SUCTION FLAP TO DELAY SEPARATION OF AIR FLOW FROM THE LEADING EDGE OF A 35° SWEPTBACK WING. Curt A. Holzhauser and Robert K. Martin. December 1953. 42p. diagrs., photos., tabs. (NACA RM A53J26)

The aerodynamic characteristics and suction requirements for a 35° swept-wing model having a 40° leading edge area-suction flap were compared with those obtained on the same model having leading edge area suction (NACA RM A53E06). The measurements also included pressure distributions over the wing. The free-stream velocity range of the test was from 112 to 166 feet per second. It was found that comparable delays in air-flow separation from the forward portion of the wing were obtained by the two methods of boundary-layer control. However, the power required for the 40° leading edge area-suction flap was about one-tenth of that required for leading edge area suction at the same angle of attack.

NACA RM A54A25

THE USE OF AREA SUCTION TO INCREASE THE EFFECTIVENESS OF A TRAILING-EDGE FLAP ON A TRIANGULAR WING OF ASPECT RATIO 2. Mark W. Kelly and William H. Tolhurst, Jr. April 1954. 44p. diagrs., photos. (NACA RM A54A25)

An investigation was conducted to determine the effectiveness of area suction applied to the leading edge of a partial-span trailing-edge flap on a triangular wing of aspect ratio 2. The investigation covered a Reynolds number range from 9.8 to 18.2 x 10^6. The results indicated that high lift at relatively low attitudes can be obtained from this configuration with low suction flow requirements. Measurements of lift, drag, pitching moment, pressure distribution on the wing and flap, and suction requirements are presented.

NACA RM A54J22

THE PRESSURE-RECOVERY AND PROPELLER-FORCE CHARACTERISTICS OF A PROPELLER-SPINNER-COWLING COMBINATION EMPLOYING NACA 4-(5)(05)-037 SIX- AND EIGHT-BLADE DUAL-ROTATION PROPELLERS WITH AN NACA 1-SERIES D-TYPE COWL. Robert I. Sammonds and Robert M. Reynolds. January 1955. 98p. diagrs., photos., tabs. (NACA RM A54J22)

The pressure recovery and propeller force characteristics of six- and eight-blade dual-rotation propeller-spinner-cowling combinations are presented for various propeller blade angles, inlet velocity ratios, and advance ratios at Mach numbers up to 0.84. All tests were made at a Reynolds number of 1.3 million, based on the maximum cowl diameter.

NACA RM A55I09

FULL-SCALE WIND-TUNNEL TESTS OF A 35° SWEPTBACK WING AIRPLANE WITH HIGH-VELOCITY BLOWING OVER THE TRAILING-EDGE FLAPS. Mark W. Kelly and William H. Tolhurst, Jr. November 1955. 49p. diagrs., photos., tab. (NACA RM A55I09)

A wind-tunnel investigation was conducted to determine the effects of blowing high-velocity air over the trailing-edge flaps of an airplane having a 35° swept-back wing. It was found that blowing over the flaps produced large increases in flap effectiveness for deflections from 45° to 85°. Measurements of lift, drag, pitching moment, and blowing-air requirements are presented for Reynolds numbers from 5.8 to 10.1 x 10^6.

EXPERIMENTAL PRESSURE DISTRIBUTIONS OVER TWO WING-BODY COMBINATIONS AT MACH NUMBER 1.9. Barry Moskowitz and Stephen H. Maslen. February 5, 1951. 31p. diagrs., photos. (NACA RM E50J09)

Pressure distributions on two wing-body combinations were obtained at Mach number of 1.9 to investigate wing-body interference. A rectangular wing, a triangular wing, and a cylindrical body having an ogive nose were investigated alone and in combination. Pressure distributions over the wing-body combination compared favorably with theoretical calculations based primarily on a generalization of the method of Nielsen and Matteson, except at the root section of wings where boundary layer of body modified the flow.

NACA RM E51J08

PRELIMINARY INVESTIGATION OF USE OF CONICAL FLOW SEPARATION FOR EFFICIENT SUPERSONIC DIFFUSION. W. E. Moeckel and P. J. Evans, Jr. December 1951. 15p. photos., diagrs. (NACA RM E51J08)

Use of flow separation on a rod projecting upstream of a blunt body to decelerate the supersonic stream ahead of an annular nose inlet was investigated at Mach numbers of 1.76, 1.93, and 2.10. Maximum pressure recoveries were obtained with rod tip projections about 1.5 times the radius of the spherical nose and were higher than those obtained with single-shock solid cones. Subcritical operation was similar to that observed with solid-cone inlets, but the effect of angle of attack on maximum pressure recovery was more severe.

NACA RM E51J22

EXPERIMENTAL INVESTIGATION OF EFFECT OF JET EXIT CONFIGURATION ON THRUST AND DRAG. Edmund E. Callaghan and Willard D. Coles. December 1951. 18p. diagrs., photos. (NACA RM E51J22)

Performance losses occurring when airplanes equipped with afterburner and cooling-air ejector installations were flown with the afterburner inoperative were investigated. These losses were found to have two sources: either excessive ejector pumping or overexpansion of the propulsive jet. The effect of a partial shroud on performance appeared negligible at pressure ratios as high as 4.0.

NACA RM E52I11

PHOTOGRAPHIC STUDIES OF PREIGNITION ENVIRONMENT AND FLAME INITIATION IN TURBOJET-ENGINE COMBUSTORS. David M. Straight and J. Dean Gernon. February 1953. 40p. photos., diagrs. (NACA RM E52I11)

Preignition environment and flame initiation in turbojet combustors were studied in transparent combustors by photographic techniques. The concept of reverse air flow in a combustor primary zone was substantiated. Fuel atomization was improved by air turbulence in the combustor and by change in fuel-nozzle design. The initial flame spreading from the ignition source followed the preignition air-flow patterns. Better understanding of the effect of spark-electrode position and other design variables on starting performance may be obtained from this type of photographic study.

NACA RM E52J21

EFFECT OF FUEL VOLATILITY CHARACTERISTICS ON IGNITION-ENERGY REQUIREMENTS IN A TURBOJET COMBUSTOR. Hampton H. Foster and David M. Straight. January 1953. 32p. diagrs., tab. (NACA RM E52J21)

The effect of fuel-volatility characteristics on the ignition-energy requirements in a turbojet combustor was investigated. Data were obtained at simulated static sea-level engine starting conditions for a wide range of combustor-inlet air and fuel temperatures and also for a range of altitude inlet-air pressures and two air flows. In order to determine the relative ignition characteristics of the fuels at various combustor-inlet pressures and two air flows, a relation between the minimum ignition-energy requirements and an empirical function of combustor inlet-air pressure and velocity ($V/\sqrt{P}$) was developed. The data obtained at both sea-level and altitude conditions showed that the A. S. T. M. 15-percent evaporated temperatures of the fuels were generally indicative of their ignition characteristics; whereas, the Reid vapor pressures of the fuels were not.

NACA RM L8G29

FLIGHT INVESTIGATION TO DETERMINE THE AERODYNAMIC CHARACTERISTICS OF ROCKET-POWERED MODELS REPRESENTATIVE OF A FIGHTER-TYPE AIRPLANE CONFIGURATION INCORPORATING AN INVERSE-TAPER WING AND A VEE TAIL. Sidney R. Alexander. November 2, 1948. 29p. diagrs., photos., tab. (NACA RM L8G29)

Two rocket-powered models representative of a fighter-type airplane configuration having an inverse-taper wing and a vee tail were investigated in flight at Mach numbers up to 1.01 and 1.07 by the Langley Pilotless Aircraft Research Division at its testing station at Wallops Island, Va. These models incorporated a tail length of 1.56 mean aerodynamic chords and were flown with controls undeflected and wing and stabilizers set at 0° incidence. Values of lateral acceleration, normal acceleration, velocity, and drag were obtained by use of a telemeter and a Doppler velocimeter radar unit.

NACA RM L9J26

COMPARATIVE TESTS OF THE ROLLING EFFECTIVENESS OF CONSTANT-CHORD, FULL-DELTA, AND HALF-DELTA AILERONS ON DELTA WINGS AT TRANSONIC AND SUPERSONIC SPEEDS. Carl A. Sandahl and H. Kurt Strass. December 12, 1949. 26p. diagrs., photos., tab. (NACA RM L9J26)

Comparative tests of the rolling power of plain constant-chord, full-delta, and half-delta ailerons on

delta wings having 45° and 60° leading-edge sweepback have been made utilizing rocket-propelled test vehicles in free flight. The results are compared with theory.

NACA RM L51J22a

WIND-TUNNEL INVESTIGATION AT TRANSONIC SPEEDS OF A LEADING-EDGE SLAT ON A MODIFIED-DOUBLE-WEDGE WING. Richard G. MacLeod. December 1951. 12p. diagrs. (NACA RM L51J22a)

Contains results at a Reynolds number of about 1×10^6 and at Mach numbers from 0.6 to 1.10 of a preliminary investigation on a leading-edge slat on a modified-double-wedge wing. Results indicated that the gain obtained in maximum lift at low Mach numbers by deflecting the slat was not maintained through the Mach number range. Below the stall a drag increase and a diving moment resulted through the Mach number range when the slat was deflected.

NACA RM L51J29

JET EFFECTS ON PRESSURES AND DRAGS OF BODIES. Warren Gillespie, Jr. November 1951. 12p. diagrs. (NACA RM L51J29)

Experimental results of recent investigations by the Lewis and Langley laboratories of the jet effect on body end pressures and drag at zero lift indicate that a decrease in base drag can be obtained by a small amount of jet flow to the base. A large base annulus may contribute as much or greater base drag during power-on conditions than the whole base area during power-off flight. The jet effect on body side pressures at supersonic Mach numbers decreases rapidly with increasing Mach number and distance forward of the base. More extensive measurements are required to clarify the jet effect on total drag.

NACA RM L52D02

EXPERIMENTAL INVESTIGATION OF BOUNDARY-LAYER SUCTION THROUGH SLOTS TO OBTAIN EXTENSIVE LAMINAR BOUNDARY LAYERS ON A 15-PERCENT-THICK AIRFOIL SECTION AT HIGH REYNOLDS NUMBERS. Laurence K. Loftin, Jr., and Elmer A. Horton. June 1952. 38p. diagrs., photos., tabs. (NACA RM L52D02)

The results presented indicate that essentially full-chord laminar flow with large net drag savings can be obtained through the use of multiple suction slots for Reynolds numbers as high as 16.0×10^6 to 17.0×10^6. These results, however, could be obtained only after a very high degree of surface excellence had been achieved on the model.

NACA RM L52J01

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE INTERFERENCE BETWEEN A 45° SWEPTBACK WING AND A SYSTEMATIC SERIES OF FOUR BODIES. Donald L. Loving and Dewey E. Wornom. November 1952. 42p. diagrs., photos., tabs. (NACA RM L52J01)

The interference between a 45° sweptback wing and a systematic series of four bodies is presented for subsonic and transonic speeds. Measurements were made at nonlifting and lifting conditions for the various wing-body configurations and the bodies alone at Mach numbers from 0.60 to 1.13. Analysis showed that the principal effects of the various body shapes on the wing-body interference occurred in the transonic range, with the drag characteristics being most significantly affected. The changes to the original body shape decreased the zero-lift drag rise of the wing with interference and increased the lift-drag ratio at transonic speeds. The modifications had significant effects on the drag characteristics of the bodies alone at transonic speeds and the pitching-moment characteristics throughout the speed range tested.

NACA RM L52J07

A STUDY OF THE USE OF FREON-12 AS A WIND-TUNNEL TESTING MEDIUM AT LOW SUPERSONIC MACH NUMBERS. Milton A. Schwartzberg. November 1952. 24p. diagrs., photo. (NACA RM L52J07)

Pressure distributions measured on a 45° sweptback wing in Freon-12 at a low supersonic Mach number are compared with similar measurements made in air. Small differences between the data obtained in the two gases are resolved by application of conversion factors derived from the concept of geometrical similarity of the flow pattern in the two gases.

NACA RM L52J22

A SMALL-SCALE INVESTIGATION OF THE EFFECT OF SPANWISE AND CHORDWISE POSITIONING OF AN OGIVE-CYLINDER UNDERWING NACELLE ON THE HIGH-SPEED AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK TAPERED-IN-THICKNESS WING OF ASPECT RATIO 6. H. Norman Silvers and Thomas J. King, Jr. December 1952. 57p. diagrs., tab. (NACA RM L52J22)

An investigation of a nacelle in several spanwise and chordwise locations was made at Mach numbers from 0.7 to 1.08 on a semispan wing with 45° sweepback, an aspect ratio of 6, and a taper ratio of 0.6 with an NACA 65A-series section tapering from root in thickness ratio from 9 percent to 3 percent. The nacelle, a solid body of revolution of fineness ratio 9.34, was composed of a cylinder with ogival nose and tail.

NACA RM L52J28

CONTROL CHARACTERISTICS OF TRAILING-EDGE SPOILERS ON UNTAPERED BLUNT TRAILING-EDGE WINGS OF ASPECT RATIO 2.7 WITH 0° AND 45° SWEEPBACK AT MACH NUMBERS OF 1.41 AND 1.96. Carl R. Jacobsen. December 1952. 35p. diagrs., photo. (NACA RM L52J28)

An investigation has been made in the Langley 9- by 12-inch supersonic blowdown tunnel to determine the control characteristics of full-span trailing-edge spoilers on several blunt trailing-edge wings of aspect ratio 2.7 at Mach numbers of 1.41 and 1.96. The tests were made at spoiler projections up to 6 percent of the wing chord and at angles of attack up to 25°. The Reynolds numbers for the tests ranged from 1.3×10^6 to 2.3×10^6. Full-span spoilers were tested at the 70-percent-chord line and at the trailing edge of both the unswept and 45° sweptback wings. A trailing-edge spoiler, which pivoted about the 85-percent-chord line of the wing, was also tested on an unswept wing with the trailing-edge thickness equal to one-third of the maximum thickness.

NACA RM L52J29

LOW-SPEED WIND-TUNNEL INVESTIGATION OF A THIN 60° DELTA WING WITH DOUBLE SLOTTED, SINGLE SLOTTED, PLAIN, AND SPLIT FLAPS. John M. Riebe and Richard G. MacLeod. January 1953. 57p. diagrs., photo., tabs. (NACA RM L52J29)

Results are presented of a wind-tunnel investigation at low speeds of a thin delta wing equipped with double slotted, single slotted, plain, and split flaps. Results of the double-slotted-flap configuration indicated an increase in the lift-drag ratio from a lift coefficient of 0.8 up to the stall. The double-slotted-flap configuration tested resulted in an increment of lift coefficient of about 0.96 at zero angle of attack and an increase in maximum lift coefficient of 0.36.

NACA RM L53J05

INVESTIGATION AT TRANSONIC SPEEDS OF THE LATERAL-CONTROL AND HINGE-MOMENT CHARACTERISTICS OF A FLAP-TYPE SPOILER AILERON ON A 60° DELTA WING. Harleth G. Wiley and Robert T. Taylor. January 1954. 22p. diagrs. (NACA RM L53J05)

This paper presents results of an investigation of the lateral-control and hinge-moment characteristics of a 0.67 semispan flap-type spoiler aileron on a semispan thin 60° delta wing at transonic speeds by the reflection-plane technique. The spoiler-aileron had a constant chord of 10.29 percent mean aerodynamic chord and was hinged at the 81.9-percent-wing-root-chord station. Tests were made with the spoiler aileron slot open, partially closed, and closed. Incremental rolling-moment, incremental yawing-moment, and hinge-moment coefficients were obtained through a Mach number range of 0.62 to 1.08. Results indicated reasonably linear variations of rolling-moment and hinge-moment coefficients with spoiler projection except at spoiler projections of less than -2 percent mean aerodynamic chord and angles of attack greater than 12° with results generally independent of slot geometry.

NACA RM L53J05a

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE EFFECT OF SPOILER PROFILE ON THE LATERAL CONTROL CHARACTERISTICS OF A WING-FUSELAGE COMBINATION WITH QUARTER-CHORD LINE SWEPT BACK 32.6° AND NACA 65A006 AIRFOIL SECTION. Harold S. Johnson. November 1953. 15p. diagrs. (NACA RM L53J05a)

This paper contains the results of a wind-tunnel investigation made through a Mach number range of 0.39 to 0.89 to determine the effect of spoiler profile on the lateral control characteristics of a wing-fuselage model. Included are rolling- and yawing-moment data through an angle-of-attack range from 0° to about 8° for each of four 49.7-percent-semispan inboard spoilers located on the 70-percent-chord line of the aspect-ratio-4, taper-ratio-0.6 wing which had a quarter-chord sweepback of 32.6° and an NACA 65A006 airfoil section. The spoiler profiles investigated were a right-angle spoiler, forward- and rearward-hinged flap-type spoilers, and a spoiler obtained by joining the forward- and rearward-hinged flap-type spoilers at the line of maximum projection. Also included are lift, drag, and pitching-moment data for the wing-fuselage combination without spoilers.

NACA RM L53J09b

APPLICATION OF TRANSONIC AREA RULE TO A SHARP-LIPPED DUCTED NACELLE. Richard E. Walters. January 1954. 11p. diagrs., tab. (NACA RM L53J09b)

The transonic area rule concept has been applied to normal-shock, sharp-lipped inlet configurations by replacing them with bodies of equivalent area distributions. The drag results from the equivalent bodies confirm the application of the rule in these cases.

NACA RM L53J12a

LONGITUDINAL STABILITY AND TRIM OF TWO ROCKET-PROPELLED AIRPLANE MODELS HAVING 45° SWEPTBACK WINGS AND TAILS WITH THE HORIZONTAL TAIL MOUNTED IN TWO POSITIONS. James H. Parks and Alan B. Kehlet. December 1953. 26p. diagrs., photos. (NACA RM L53J12a)

The longitudinal stability and trim characteristics of two rocket-propelled airplane models with swept wings and fixed horizontal tails of the same geometry but located at different positions were investigated in free flight at Mach numbers from about 0.6 to 1.4. Static- and dynamic-longitudinal stability parameters, values of trim lift coefficient and angle of attack, and vibration characteristics of the horizontal tails are presented. The results are presented with some observations but without analysis.

NACA RM L53J15

THE INFLUENCE OF THE CONTROL-SURFACE-SERVO NATURAL FREQUENCY UPON THE TRANSIENT CHARACTERISTICS OF A FLIGHT-PATH-ANGLE CONTROL SYSTEM INCORPORATING A SUPERSONIC MISSILE. Anthony L. Passera and Thomas F. Bridgland, Jr. December 1953. 22p. diagrs., photo., tabs. (NACA RM L53J15)

A theoretical investigation has been made to determine the effect of the natural frequency of a second-order control-surface servo upon the transient characteristics of a supersonic canard missile configuration in a flight-path-angle control system for several flight conditions and static margins. These effects are presented as plots of response time, attitude accuracy, peak rate and total volume of oil flow through the servo, and maximum normal acceleration of the airframe against control-surface-servo natural frequency in response to a unit step command input.

NACA RM L53J21

WIND-TUNNEL INVESTIGATION AT TRANSONIC SPEEDS OF A SPOILER-SLOT-DEFLECTOR COMBINATION ON AN UNSWEPT NACA 65A006 WING. Raymond D. Vogler. December 1953. 27p. diagrs., 3 tabs. (NACA RM L53J21)

Results are presented of a wind-tunnel investigation at transonic speeds and angles of attack up to 24° to determine the lateral control characteristics of a spoiler, a spoiler-gap-lip combination, and a spoiler-slot-deflector combination. The spoiler-slot-deflector combination showed good rolling effectiveness throughout the angle-of-attack and Mach number range investigated.

NACA RM L53J22

EFFECTS OF EXTERNAL STORE MOUNTING ON THE BUFFET, TRIM, AND DRAG CHARACTERISTICS OF ROCKET-POWERED FUSELAGE AND STORE COMBINATIONS BETWEEN MACH NUMBERS OF 0.7 AND 1.4. Homer P. Mason. December 1953. 27p. diagrs., photos., tab. (NACA RM L53J22)

An investigation has been made of the effects of store mounting on the buffet, trim, and drag characteristics of fuselage-mounted external stores between Mach numbers of 0.7 and 1.4 using the rocket propelled model technique. Four models have been tested which consisted of wingless parabolic fuselages with finless models of a 10,000-pound large-diameter bomb located at the same longitudinal stations with various store mounting arrangements. The mounting arrangements tested were a semisubmerged store, a store mounted tangent to the fuselage, a store mounted on a 10-percent-thick pylon, and a store mounted on a 4-percent-thick pylon. In conjunction with these tests, a model has been flown by the helium-gun technique to obtain the drag of the isolated store. Data from these tests show that strong interference effects about fuselage-mounted external stores may produce severe buffeting and large drag increments.

NACA RM L53J26

LOW-SPEED INVESTIGATION OF THE EFFECTS OF LOCATION OF A DELTA AND A STRAIGHT TAIL ON THE LONGITUDINAL STABILITY AND CONTROL OF A THIN DELTA WING WITH EXTENDED DOUBLE SLOTTED FLAPS. John M. Riebe and Jean C. Graven, Jr. January 1954. 49p. diagrs., tabs. (NACA RM L53J26)

Results are presented of a wind-tunnel investigation at low speeds of the effect of horizontal-tail location and plan form on the longitudinal stability and control characteristics of a thin delta wing with extended double slotted flaps including the effects of a retractable canard horizontal surface. An investigation was also made of a Fowler type flap. Satisfactory locations of horizontal tail with flaps deflected were indicated to be lower and farther to the rear than for the flap-retracted condition. With regard to stability and control, a delta-plan-form tail was generally found to be superior to a moderately swept tail. Use of the canard with the extended double slotted flap and a delta tail generally resulted in a longitudinally stable high-lift configuration with a trim lift coefficient of 0.82 at an angle of attack of 0° and a maximum trim lift coefficient of 2.30.

NACA RM L54C05

EFFECT ON THE LOW-SPEED AERODYNAMIC CHARACTERISTICS OF A 49° SWEPTBACK WING HAVING AN ASPECT RATIO OF 3.78 OF BLOWING AIR OVER THE TRAILING-EDGE FLAP AND AILERON. Edward F. Whittle, Jr., and Stanley Lipson. April 1954. 51p. diagrs., photo., tab. (NACA RM L54C05)

An investigation was made in the Langley full-scale tunnel to determine the effect on aerodynamic characteristics of a semispan 49.1° sweptback wing of blowing a high-energy stream of air over a trailing-edge flap and an aileron with and without a slat and fences. The wing had an aspect ratio of 3.78, a taper ratio of 0.59, and NACA 65A006 airfoil sections parallel to the plane of symmetry. Rolling moments produced by a flap-type aileron were measured and flap pressures were obtained at one spanwise station. The data were obtained at Reynolds numbers of 2.9×10^6, 4.4×10^6, and 6.1×10^6 corresponding to Mach numbers of 0.05, 0.07, and 0.10, respectively.

NACA RM L54G09

GROUND TESTS OF THE ELEVATOR POWER CONTROL SYSTEM AND FEEL DEVICE IN A BOEING B-47A AIRPLANE. B. Porter Brown. October 1954. 34p. diagrs. (NACA RM L54G09)

Ground tests were made on the elevator power control system and feel device of a Boeing B-47A airplane. Frequency-response measurements were made by oscillating the control stick sinusoidally while recording the stick force, stick angle, and elevator angle. Tests were also made involving a simulator which affords the pilot a visual indication of the airplane response to control motions. All tests were made at various equivalent airspeeds which were simulated by applying the appropriate air pressure to the feel device Q-spring.

NACA RM L54J22

A LIMITED ANALYSIS OF BUFFETING EXPERIENCE IN FLIGHT BY A NORTH AMERICAN F-86A-1 AIRPLANE WITH AND WITHOUT LARGE EXTERNAL FUEL TANKS. Jim Rogers Thompson, Thomas C. O'Bryan, and Max C. Kurbjun. September 1955. 40p. diagrs., photo. (NACA RM L54J22)

A limited analysis of buffeting experienced by a North American F-86A-1 airplane with and without large external fuel tanks installed (extending to severe buffeting at maximum Mach numbers of 0.88 with tanks and 1.0 without tanks) has been performed in order to explore the buffeting characteristics of such configurations. The analysis consists of two parts: The effect of the tanks on the general buffeting characteristics throughout the investigated range, and detail study by frequency analysis methods of one run in the low-lift high Mach number buffeting region.

NACA RM L54J28a

WIND-TUNNEL INVESTIGATION AT TRANSONIC SPEEDS OF THE LIFT AND HINGE-MOMENT CHARACTERISTICS OF A FLAP WITH ATTACHED BALANCING TAB ON A 45° SWEPTBACK WING. Raymond D. Vogler. December 1954. 63p. diagrs. (NACA RM L54J28a)

Lift and hinge moments of a low-aspect-ratio sweptback wing with a flap and a balancing tab attached to the inboard trailing edge of the flap were obtained for a Mach range from 0.75 to 1.20. Data were obtained for a range of tab deflection between 10° unbalancing and 30° balancing, flap deflections between ±20°, and angles of attack from -2° to 16°. For flap balance, a tab-flap deflection ratio of approximately 1 subsonically and 1.5 supersonically was indicated. The lift effectiveness of the balanced flap was 67 to 80 percent of that of the unbalanced flap.

NACA RM L55D29a

A CORRELATION OF TWO-DIMENSIONAL DATA ON LIFT COEFFICIENT AVAILABLE WITH BLOWING-, SUCTION-, SLOTTED-, AND PLAIN-FLAP HIGH-LIFT DEVICES. John M. Riebe. October 1955. 32p. diagrs. (NACA RM L55D29a)

This paper contains results of a correlation of the available two-dimensional data on flap-type high-lift devices including plain, single slotted, and double slotted flaps and suction and blowing flaps which utilized boundary-layer control by suction and by jet flow, respectively. The flap-chord ratios ranged from 20 to 40 percent wing chord. The correlation indicated that the largest lift increments were obtained for the blowing flaps. Flap-chord ratio had a large effect on the momentum coefficient required to obtain a given lift coefficient with minimum momentum coefficient required in the flap-chord ratio range greater than 0.30 and less than 0.40.

NACA RM L55E11a

RECENT STABILITY AND AERODYNAMIC PROBLEMS AND THEIR IMPLICATIONS AS TO LOAD ESTIMATION. Charles H. Zimmerman. June 1955. 12p. diagrs. (NACA RM L55E11a)

Modern fighter airplanes tend to suffer from stability deficiencies which can give rise to inadvertent high structural loads. These deficiencies are briefly described and discussed.

NACA RM L55F02

AERODYNAMIC CHARACTERISTICS AND PRESSURE DISTRIBUTIONS OF A 6-PERCENT-THICK 49° SWEPTBACK WING WITH BLOWING OVER HALF-SPAN AND FULL-SPAN FLAPS. Edward F. Whittle, Jr., and H. Clyde McLemore. September 1955. 71p. diagrs., photo., tabs. (NACA RM L55F02)

An investigation was made in the Langley full-scale tunnel to determine the effect on aerodynamic characteristics and chordwise and spanwise loadings of a semispan 49.1° sweptback wing of blowing a high-energy stream of air over half-span and full-span trailing-edge flaps with and without a slat and a fence installed. The wing had an aspect ratio of 3.22, a taper ratio of 0.64, and NACA 65A006 airfoil sections parallel to the plane of symmetry. The data were obtained in a Reynolds number range from 3.0×10^6 to 7.5×10^6 corresponding to a Mach number range from 0.05 to 0.12. The momentum-coefficient range investigated was from 0.08 to 0.38.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1257

ON THE KERNEL FUNCTION OF THE INTEGRAL EQUATION RELATING LIFT AND DOWNWASH DISTRIBUTIONS OF OSCILLATING WINGS IN SUPERSONIC FLOW. Charles E. Watkins and Julian H. Berman. 1956. ii, 18p. diagrs. (NACA Rept. 1257. Supersedes TN 3438)

A suitable form of doublet potential that serves as a basis for deriving the kernel function for supersonic flow, corresponding to the kernel function for subsonic flow presented in NACA Report 1234, is derived by using a cutoff or unit function. A treatment similar to that made for the subsonic kernel is made for the kernel function for supersonic flow. The singularities are isolated and discussed, and the kernel function is shown to lead to correct results for two-dimensional flow, and to reduce properly to the sonic case.

NACA RM E56G17

METHODS FOR MEASURING TEMPERATURES OF THIN-WALLED GAS-TURBINE BLADES. Francis S. Stepka and Robert O. Hickel. November 1956. 25p. diagrs., photos., tab. (NACA RM E56G17)

The accuracy and durability of two means for measuring the metal temperature of gas-turbine blades were investigated experimentally in a turbojet engine. Cemented thermocouples that could be placed in walls as thin as 0.010 inch and commercial temperature-indicating paints were evaluated at turbine-inlet temperatures up to about 1650° F and for centrifugal forces equivalent to about 42,000 times gravity. The cemented thermocouples operated satisfactorily. The temperature-indicating paints were neither as accurate nor as durable as the cemented thermocouples.

NACA TM 1402

AEROELASTIC PROBLEMS OF AIRPLANE DESIGN. (Aeroelastische Probleme des Flugzeugbaus). H. G. Küssner. November 1956. 51p. tabs. (NACA TM 1402. Translation from Zeitschrift für Flugwissenschaften, v.3, no.1, January 1955, p.1-18)

A review, based on a bibliographical selection of some 65 papers and on the author's experience, is given of some recent progress in the field of wing flutter and related matters. The review touches on phases of unsteady aerodynamics and flutter theory, model and flight testing, and on design requirements.

NACA TN 3753

AERODYNAMIC CHARACTERISTICS AND FLYING QUALITIES OF A TAILLESS TRIANGULAR-WING AIRPLANE CONFIGURATION AS OBTAINED FROM FLIGHTS OF ROCKET-PROPELLED MODELS AT TRANSONIC AND LOW SUPERSONIC SPEEDS. Grady L. Mitcham, Joseph E. Stevens, and Harry P. Norris. November 1956. 57p. diagrs., photos., tabs. (NACA TN 3753. Supersedes RM L9L07)

A flight investigation of rocket-powered models of a tailless triangular-wing airplane configuration was made through the transonic and low supersonic speed range at the Langley Pilotless Aircraft Research Station at Wallops Island, Va. An analysis of the aerodynamic coefficients, stability derivatives, and flying qualities based on the results obtained from the successful flight tests of three models is presented.

NACA TN 3775

CRASH INJURY. Gerard J. Pesman and A. Martin Eiband. November 1956. 36p. diagrs., photos. (NACA TN 3775)

Data from full-scale experimental airplane crashes were studied to determine how impact injuries occur and how the chance of such injuries may be reduced. The following hazards were considered: (1) being crushed, (2) being struck by missiles, (3) striking objects by tearing loose or flailing about, and (4) being injured by the crash decelerations. Transport, cargo, fighter, and light airplane crashes were studied.

NACA TN 3778

ANALYSIS OF ELASTIC THERMAL STRESSES IN THIN PLATE WITH SPANWISE AND CHORDWISE VARIATIONS OF TEMPERATURE AND THICKNESS. Alexander Mendelson and Marvin Hirschberg. November 1956. 41p. diagrs. (NACA TN 3778)

An approximate method for calculating thermal stresses in a thin plate with variable thickness and temperature distributions in both the spanwise and chordwise directions is presented. Several examples are worked out and plotted.

NACA TN 3809

A METHOD FOR CALCULATION OF FREE-SPACE SOUND PRESSURES NEAR A PROPELLER IN FLIGHT INCLUDING CONSIDERATIONS OF THE CHORDWISE BLADE LOADING. Charles E. Watkins and Barbara J. Durling. November 1956. 68p. diagrs., tabs. (NACA TN 3809)

This report presents tabulated values of certain definite integrals that are involved in the calculation of near-field propeller noise when the chordwise forces are assumed to be either uniform or of a Dirac delta type. The tabulations are over a wide range of operating conditions and are useful for estimating propeller noise when either the concept of an effective radius or radial distributions of forces are considered. Use of the tabulations is illustrated by several examples of calculated results for some specific propellers.

NACA TN 3813

COMPARISON OF THEORETICAL STRESSES AND DEFLECTIONS OF MULTICELL WINGS WITH EXPERIMENTAL RESULTS OBTAINED FROM PLASTIC MODELS. George W. Zender. November 1956. 32p. diagrs., photos. (NACA TN 3813)

The experimental deflections and stresses of six plastic multicell-wing models of unswept, delta, and swept plan form are presented and compared with previously published theoretical results obtained by the electrical analog method. The comparisons indicate that the theory is reliable except for the evaluation of stresses in the vicinity of the leading edge of delta wings and the leading and trailing edges of swept wings. The stresses in these regions are questionable, apparently because of simplifications employed in idealizing the actual structure for theoretical purposes and because of local effects of concentrated loads.

NACA TN 3815

ON SLENDER-BODY THEORY AND THE AREA RULE AT TRANSONIC SPEEDS. Keith C. Harder and E. B. Klunker. November 1956. 14p. (NACA TN 3815. Supersedes RM L54A29a)

The basic ideas of the slender-body approximation have been applied to the nonlinear transonic-flow equation for the velocity potential in order to obtain some of the essential features of slender-body theory at transonic speeds. The results of the investigation are presented from a unified point of view which demonstrates the similarity of slender-body solutions in the various Mach number ranges. The transonic area rule and some conditions concerning its validity follow from the analysis.

NACA TN 3818

WIND-TUNNEL INVESTIGATION TO DETERMINE THE HORIZONTAL- AND VERTICAL-TAIL CONTRIBUTIONS TO THE STATIC LATERAL STABILITY CHARACTERISTICS OF A COMPLETE-MODEL SWEPT-WING CONFIGURATION AT HIGH SUBSONIC SPEEDS. James W. Wiggins, Richard E. Kuhn, and Paul G. Fournier. November 1956. 34p. diagrs., photo. (NACA TN 3818. Supersedes RM L53E19)

Results are presented of an investigation made in the Langley high-speed 7- by 10-foot tunnel to determine the horizontal- and vertical-tail contributions to the static lateral stability of a complete-model configuration. The general research model was tested through a Mach number range from 0.40 to 0.95 and an angle-of-attack range from -3° to 25° at angles of sideslip of $\pm 4^{\circ}$.

NACA TN 3820

SOME OBSERVATIONS ON MAXIMUM PRESSURE RISE ACROSS SHOCKS WITHOUT BOUNDARY-LAYER SEPARATION ON AIRFOILS AT TRANSONIC SPEEDS. Walter F. Lindsey and Patrick J. Johnston. November 1956. 27p. diagrs., photos. (NACA TN 3820)

An investigation of the flow along flat plates having rounded leading edges has provided additional information on shock-induced separation. The results are compared with data from two-dimensional airfoil investigations and indicate that laminar boundary layers can sustain theoretical pressure rises for normal shocks without separating. The permissible pressure rise increases with increase in angle of attack and proximity of shock to the leading edge of the flat plate or the airfoil.

NACA TN 3830

GROWTH OF DISTURBANCES IN A FLAME-GENERATED SHEAR REGION. Perry L. Blackshear, Jr. November 1956. iv, 148p. diagrs., photos., tabs. (NACA TN 3830)

This paper contains a stability analysis of the flow field that arises when a flame is anchored in a duct and an experimental examination of the growth of disturbances imposed on an anchored V-flame in a duct. The stability analysis shows that the flow is stable to all symmetric disturbances, and unstable to antisymmetric disturbances having wavelengths greater than the critical wavelength. This critical value is 2-1/2 times the local flame width for flames filling a small fraction of the duct and becomes infinite when the flame fills the duct. Roughly similar results obtain for the V-flame. The rate of heat release in a flame in a duct can be increased by introducing disturbances that the flame zone can amplify.

NACA TN 3832

ON POSSIBLE SIMILARITY SOLUTIONS FOR THREE-DIMENSIONAL INCOMPRESSIBLE LAMINAR BOUNDARY LAYERS. II - SIMILARITY WITH RESPECT TO STATIONARY POLAR COORDINATES. Howard Z. Herzig and Arthur G. Hansen. November 1956. 16p. tab. (NACA TN 3832)

Solutions of mainstream flow patterns for three-dimensional, laminar, incompressible thin-boundary-layer flows (over flat or slightly curved surfaces) having similarity with respect to stationary polar coordinates in the plane of the surface are derived. The solutions are summarized in a table.

NACA TN 3833

STABILITY LIMITS AND BURNING VELOCITIES OF LAMINAR HYDROGEN-AIR FLAMES AT REDUCED PRESSURE. Burton Fine. November 1956. 29p. diagrs., tab. (NACA TN 3833)

Laminar burning velocity was measured at pressures of 1 atm and below and critical boundary velocity gradient for flashback below 1 atm over a range of compositions for hydrogen-air burner flames. Both quantities were correlated with pressure, the pressure dependence being independent of composition between equivalence ratios of about 1 and 2. A more general correlation involving quenching distance conformed to a simple quenching model. From this correlation and thermal equations for flame propagation, a reaction order was calculated. The general laminar stability loop was discussed in terms of quenching regions, normal laminar regions, and regions of laminar-turbulent transition.

NACA TN 3837

INVESTIGATION OF HEAT TRANSFER FROM A STATIONARY AND ROTATING ELLIPSOIDAL FOREBODY OF FINENESS RATIO 3. James P. Lewis and Robert S. Ruggeri. November 1956. 46p. diagrs., photo., tabs. (NACA TN 3837)

Experimental convective heat transfer was obtained for a 20-inch-diameter forebody for airspeeds up to 240 knots, rotational speeds up to 1200 rpm, angles of attack of 0°, 3°, and 6°, and both uniform surface temperature and uniform input heat density. The results agree well with theoretical predictions. Effects of rotation were insignificant, and effects of angle of attack only minor. Transition from laminar to turbulent heat transfer varied over a Reynolds number range of 0.8×10^6 to 5×10^6. Limited transient heating data indicated that the change of surface temperature with time followed an exponential relation.

NACA TN 3838

PERFORMANCE CHARACTERISTICS OF RING-CASCADE-TYPE THRUST REVERSERS. Jack G. McArdle. November 1956. 53p. diagrs., photos., tab. (NACA TN 3838)

Model thrust reversers consisting of a cascade of turning rings plus a mechanical deflector positioned aft of a 4-inch exhaust nozzle with a 7° external fairing were tested in quiescent air at exhaust-nozzle pressure ratios up to 2.5. Reverse-thrust ratios up to 68 percent were obtained. The effects of several geometric design variables on performance and reversed-flow fields were measured. The modulation characteristics of a typical shrouded ring-cascade reverser were found to be satisfactory.

NACA TN 3840

ANALYSIS OF PARTICLE MOTIONS FOR A CLASS OF THREE-DIMENSIONAL INCOMPRESSIBLE LAMINAR BOUNDARY LAYERS. Arthur G. Hansen and Howard Z. Herzig. November 1956. 22p. diagrs., tabs. (NACA TN 3840)

An analysis is presented for the positions of particles at various time intervals in a three-dimensional incompressible laminar boundary layer on a flat surface for main flows consisting of streamline translates having constant axial velocity. Boundary-layer particles initially arrayed on a line normal to the surface trace out twisted surfaces as they progress downstream. For viscous-flow problems where it is important to know the length of time a particle remains near a bounding surface, tables are presented to facilitate rapid computation of the residence times of boundary-layer particles for a given flow configuration.

NACA TN 3848

A STUDY OF SEVERAL FACTORS AFFECTING THE STABILITY CONTRIBUTED BY A HORIZONTAL TAIL AT VARIOUS VERTICAL POSITIONS ON A SWEPTBACK-WING AIRPLANE MODEL. Gerald V. Foster and Roland F. Griner. November 1956. 28p. diagrs., tab. (NACA TN 3848. Supersedes RM L9H19)

Results are presented of a study made in the Langley 19-foot pressure tunnel at a Reynolds number of 6.8×10^6 to determine the effects of fuselage afterbody shape, split flaps, and a reduction in the span of 0.575-span leading-edge flaps on the stability contributed by a horizontal tail at various heights to a 42° sweptback wing-fuselage combination. Results are also presented of air-flow surveys in the vicinity of the tail with the wing flaps deflected.

NACA TN 3853

COMPRESSIVE STRESS-STRAIN PROPERTIES OF 2024-T3 ALUMINUM-ALLOY SHEET AT ELEVATED TEMPERATURES. Eldon E. Mathauser. November 1956. 66p. diagrs., photo., tab. (NACA TN 3853)

Compressive stress-strain test results for 2024-T3 aluminum-alloy sheet are presented for temperatures up to 700° F and exposure times from 0.1 to 100 hours. All specimens were loaded parallel to the rolling direction of the sheet and tested at a strain rate of 0.002 per minute. Significant design data obtained from the stress-strain curves (yield stress, Young's modulus, secant and tangent moduli, and two stresses useful for determining the maximum compressive strength of plates) are presented in graphical and tabular form. A rate-process relationship is used to determine exposure time which produces a maximum yield stress for a given temperature, and a time-temperature parameter is used to present the yield stresses as a single master curve.

NACA TN 3854

COMPRESSIVE STRESS-STRAIN PROPERTIES OF 7075-T6 ALUMINUM-ALLOY SHEET AT ELEVATED TEMPERATURES. Eldon E. Mathauser. November 1956. 54p. diagrs., photo., tab. (NACA TN 3854)

Compressive stress-strain test results for 7075-T6 aluminum-alloy sheet are presented for temperatures up to 700° F and exposure times from 0.1 to 100 hours. All specimens were loaded parallel to the rolling direction of the sheet and tested at a nominal strain rate of 0.002 per minute. Significant design data obtained from the stress-strain curves (yield stress, Young's modulus, secant and tangent moduli, and two stresses useful for determining the maximum compressive strength of plates) are presented in graphical and tabular form. A time-temperature parameter derived from rate-process theory is used to present the compressive yield stresses as a single master curve.

NACA TN 3857

EXPERIMENTAL INVESTIGATION AT LOW SPEED OF THE EFFECTS OF WING POSITION ON THE STATIC STABILITY OF MODELS HAVING FUSELAGES OF VARIOUS CROSS SECTION AND UNSWEPT AND 45° SWEPTBACK SURFACES. William Letko. November 1956. 77p. diagrs., photo., tabs. (NACA TN 3857)

An experimental investigation was made to determine the effects of wing position on the low-speed static longitudinal and static lateral stability derivatives of airplane models having fuselages of square and rectangular cross sections and unswept and 45° sweptback surfaces. The results indicate that in general the effects of wing position on the static longitudinal and static lateral stability characteristics of the models with the square and rectangular fuselages are similar to those obtained with models having fuselages with circular cross sections.

NACA TN 3868

PARTICULAR SOLUTIONS FOR FLOWS AT MACH NUMBER 1. Max. A. Heaslet and Franklyn B. Fuller. November 1956. 32p. diagrs. (NACA TN 3868)

Two families of exact solutions, representing either pure subsonic or supersonic flow, are found for the small-disturbance potential equation at unit stream Mach number. Solutions are given for both two-dimensional and rotationally symmetric cases. The plane supersonic solution is closely related to Prandtl-Meyer expansion. In either case it is possible to join the supersonic solution to the subsonic; the transition is made through the mechanism of a shock wave.

NACA TN 3870

MEASUREMENT OF THE LONGITUDINAL MOMENT OF INERTIA OF A FLEXIBLE AIRPLANE. Henry A. Cole, Jr., and Frances L. Bennion. November 1956. 30p. diagrs., photos., tabs. (NACA TN 3870. Supersedes RM A55J21)

A method for measuring the longitudinal moment of inertia of a flexible airplane by ground oscillation tests is presented. The effects of flexibility on the fundamental frequency for various combinations of springs and knife edges are shown, and a method which minimizes flexibility effects is developed. A description and results of tests which were conducted by this method are presented.

NACA TN 3882

A RELATION BETWEEN BURNING VELOCITY AND QUENCHING DISTANCE. A. E. Potter, Jr., and A. L. Berlad. November 1956. 19p. diagrs., tabs. (NACA TN 3882)

The product of burning velocity and quenching distance is proportional to a term which has the character of a thermal diffusivity and a term which increases with the activation energy of the flame reaction. The quotient of burning velocity and quenching distance is proportional to the average flame reaction rate and to terms which are mildly dependent on the flame reaction activation energy and the transport properties.

ILL-CONDITIONED FLUTTER EQUATIONS AND THEIR IMPROVEMENT FOR SIMULATOR USE. E. G. Broadbent. June 1956. 23p. diagrs., tab. (RAE Tech.Note Structures 195)

If simple arbitrary modes are used as coordinates in a wing flutter calculation, the equations are ill-conditioned and cannot be solved satisfactorily on a simulator. This ill-conditioning can be avoided by transforming the flutter matrix so as to reduce the inertia couplings between like modes to zero. This transformation is described with numerical examples, and some observations are made on the general problem of choice of coordinates in a flutter calculation.

THE SAMPLING ERRORS OF TURBULENCE MEASUREMENTS. N. I. Bullen. May 1956. 18p. diagrs., tabs. (RAE Structures 208)

Estimates of atmospheric turbulence from counting accelerometer records show a large scatter. The simple assumption of a random distribution of gusts is inconsistent with this scatter. A formula which takes account of the variations in gust density is given and the calculated sampling errors for 10 ft/sec gusts are found to be about four times those calculated on the basis of a random distribution.

THERMAL DEGRADATION OF VARIOUS POLYMERS OVER THE RANGE 300°-600° C. D. Sheehan. May 1956. 19p. diagrs., tabs. (RAE Tech. Note Chem. 1280)

Residues of high-carbon content have been obtained by heating certain polymers in air and in nitrogen. Oxidation of these residues occurred at 500° C in air, but phenolic resins showed relatively low weight losses at 600° C in nitrogen. Other materials studied included chlorinated linear polymers, melamine-formaldehyde resins, polybenzyl and its naphthalene analog, and polyphenylenes prepared by Wurtz syntheses from di- and trichlorobenzenes. Full descriptions of these syntheses are given.

THE USE OF AN ARALDIT COATED IRON CASTING AS A LINER FOR A SUPERSONIC WIND TUNNEL. C. S. Brown and K. G. Winter. May 1956. 9p. diagrs. (RAE Tech. Note Aero 2443)

The use of cast iron and araldite appears to overcome the disadvantages of wooden liners. The surface finishing is no more difficult than with wood and the overall manufacturing time is comparable. The use of a pair of male templets to define the profile is recommended. Considerable care should be taken in the manufacture of the templets, and use should be made of a curvature gage during manufacture.

FATIGUE LOADINGS IN FLIGHT LOADS IN THE FUSELAGE AND NOSE UNDERCARRIAGE OF A VARSITY. E. W. Wells. May 1956. 19p. diagrs., tabs. (RAE Tech. Note Structures 193)

Flight tests have been made on a Varsity to obtain data on the fatigue loads in the fuselage and the nose undercarriage. The data are tabulated in terms of the number of load ranges of a given magnitude occurring during various ground and flight conditions. An estimate is made of the loads in a typical operational training flight to show the relative importance of the various conditions. A relationship is established between the fuselage loads and the accelerations at the aircraft c. g. when flying in turbulence; this enables the results from the flight tests to be linked to operational data obtained on gusts.

TESTS ON A SINGLE-STAGE TURBINE COMPARING THE PERFORMANCE OF TWISTED WITH UNTWISTED ROTOR BLADES. I. H. Johnston and L. R. Knight. 1956. 11p. diagrs. (ARC R & M 2927; ARC 15,999. Supersedes NGTE Memo. M. 174)

An experimental single-stage turbine designed for the testing of a variety of blade forms with cold air is described together with the instrumentation provided for test measurements. Performance results obtained on this unit from two rotor blade designs are presented and it is shown that for the incidence range covered by the tests an untwisted constant-section blade of about 10 percent reaction possesses characteristics of pressure loss and deflection nearly identical to those of a conventional rotor blade twisted along its length to conform to the requirements of radial equilibrium, the mean diameter sections of the two blade designs being identical.

THE INFLUENCE OF ROPE STRETCH ON TENSION VARIATIONS IN ARRESTING GEARS. N. I. Bullen. 1956. 38p. diagrs., tabs. (ARC R & M 2964; ARC 14,401. Supersedes RAE Tech. Note NA 229)

It is usual, when considering the performance of an arresting gear as a whole, to assume an inextensible rope which automatically excludes the possibility of developing oscillations in the predicted tension. A method of calculation is given which removes this limitation of inextensibility and produces results which can be related to the tension oscillations occurring in practice. The calculations are made for a constant-pressure type arresting gear and the tension oscillations are shown to be interrelated with the action of the constant-pressure valve and the general hydraulic system. The results are compared with actual values obtained from such a gear.

Aeronautical Research Council (Gt. Brit.)
THEORY OF AEROFOIL SPOILERS. L. C. Woods. 1956. 21p. diagrs., tabs. (ARC R & M 2969. Supersedes ARC 15,870, FM 1895, S & C 2774)

A mathematical theory of airfoil spoilers in two-dimensional subsonic flow is presented. Equations are given for load distribution, lift, drag, moments, and hinge moments produced by spoiler-flap combinations. The theory is developed for a spoiler in a general position but the trailing-edge spoiler receives special attention. For this important case the theory gives good agreement with experiment, but in the more general case, because of uncertainty about the pressure distribution on the airfoil to the rear of the spoiler, the agreement is not as good.

MEASUREMENT OF LIFT, PITCHING MOMENT AND HINGE MOMENT ON A TWO-DIMENSIONAL RAE 102 AEROFOIL. A. S. Batson. 1955. 30p. diagrs., tabs. (ARC CP 191)

The charts of R. & M. 2730 for estimating two-dimensional control derivatives were based mainly on data for airfoils of 15 percent thickness. Supplementary tests have been carried out on a two-dimensional 10-percent-thick RAE 102 airfoil with 20 percent and 40 percent plain round-nosed control surfaces. Lift, pitching moment, and hinge moment were determined from balance measurements and from integrated pressure distributions on one section. In most cases, consistent coefficients were obtained by the two methods. Particular care was taken in observing or fixing with wires the positions of boundary-layer transition on both surfaces of the airfoil. The experimental derivatives varied smoothly with position of transition and were in fair agreement with the general charts of R. & M. 2730.

NACA RM A51K14

EXPERIMENTAL INVESTIGATION OF THE EFFECT OF FOREBODY BLUNTNESS ON THE PRESSURE RECOVERY AND DRAG OF A TWIN-SCOOP INLET-BODY COMBINATION AT MACH NUMBERS OF 1.4 AND 1.7. John F. Stroud. February 1952. 20p. diagrs., photos. (NACA RM A51K14)

The pressure recovery, mass flow, and drag of a twin-scoop inlet-body combination were measured at Mach numbers of 1.4 and 1.7 at zero angle of attack. Tests were made of the combination with an ogival forebody and with three different forebody shapes obtained by shortening the body and increasing the nose bluntness. Pressure surveys were made just ahead of the inlets and drag values were obtained for three forebodies without inlets. Increasing the forebody bluntness caused losses in pressure recovery and maximum mass-flow ratio, and large increases in total external drag of the inlet-body combination.

NACA RM A53E06

THE USE OF AREA SUCTION FOR THE PURPOSE OF IMPROVING TRAILING-EDGE FLAP EFFECTIVENESS ON A 35° SWEPTBACK WING. Woodrow L. Cook, Curt A. Holzhauser, and Mark W. Kelly. July 1953. 77p. diagrs., photos., tabs. (NACA RM A53E06)

An investigation was conducted to determine the effectiveness of area suction applied to the leading edge of a trailing-edge flap on a 35° sweptback wing. The results indicated that with area suction the linear variation of flap increment with flap angle was retained up to at least 55° of deflection. A flap increment of lift of 0.78 was obtained with 55° deflection of the partial-span flap and a flow coefficient of 0.0005. An increment of lift of 0.87 was obtained with 70° deflection of a partial-span flap and a flow coefficient of 0.0009.

NACA RM A53K24

BUFFETING FORCES ON TWO-DIMENSIONAL AIRFOILS AS AFFECTED BY THICKNESS AND THICKNESS DISTRIBUTION. Charles F. Coe and Jack A. Mellenthin. February 1954. 26p. diagrs., photo. (NACA RM A53K24)

Seven symmetrical airfoils were tested over a Mach number range from about 0.4 to 0.9 in the two-dimensional channel in the Ames 16-foot high-speed

wind tunnel to determine the effects of thickness and of the thickness distribution on the fluctuations of normal-force and pitching-moment coefficients. The corresponding Reynolds number range was from about 4.6 million to 8 million. Thickness was varied from 12 percent to 2 percent on 65A-series airfoils, while for 8-percent-thick airfoils the thickness distribution was varied to give positions of maximum thickness from about 0.16 chord to about 0.63 chord. A 4-percent-thick circular-arc airfoil was also tested. No one of the seven airfoils tested had the lowest normal-force fluctuations over the entire range of Mach numbers and normal-force coefficients investigated.

NACA RM A54K16a

AN INVESTIGATION OF STING-SUPPORT INTERFERENCE ON BASE PRESSURE AND FOREBODY CHORD FORCE AT MACH NUMBERS FROM 0.60 TO 1.30. Phillips J. Tunnell. January 1955. 19p. diagrs. (NACA RM A54K16a)

Various configurations of rear sting supports were tested on one wing-body model with a turbulent boundary layer over the aft portion of the fuselage to determine the interference effects on the base pressure and foredrag characteristics. The tests were made at a Reynolds number of 5.4×10^6 based on fuselage length and over a Mach number range of 0.60 to 1.30.

NACA RM E50D26

EFFECT OF MACH NUMBER ON OVER-ALL PERFORMANCE OF SINGLE-STAGE AXIAL-FLOW COMPRESSOR DESIGNED FOR HIGH PRESSURE RATIO. Charles H. Voit, Donald C. Guentert, and James F. Dugan. July 10, 1950. 19p. diagrs., tab. (NACA RM E50D26)

A complete stage of an axial-flow compressor designed to produce a high pressure ratio was investigated at speeds from 110 to 130 percent of design speed (836 ft/sec). The data obtained and the results of a previous investigation of the same compressor at speeds from 50 to 100 percent of design speed were used to determine the effect of Mach number on overall performance. The peak total-pressure ratio increased from 1.095 to 1.515 and the peak adiabatic efficiency decreased from 0.93 to 0.89 as the relative inlet Mach number increased from 0.34 to 0.77. At a relative inlet Mach number of 0.91, a total-pressure ratio of 1.635 was obtained at an adiabatic efficiency of 0.74.

#NACA RM E51J23, by Wallner and Welna

NACA RM E51K05

INFLUENCE OF FUSELAGE AND CANARD-TYPE CONTROL SURFACE ON THE FLOW FIELD ADJACENT TO A REARWARD FUSELAGE STATION AT A MACH NUMBER OF 2.0 - DATA PRESENTATION. Evan A. Fradenburgh, Leonard J. Obery, and John F. Mello. January 1952. 25p. diagrs., photos. (NACA RM E51K05)

A survey of local total pressures and flow-deflection angles was made at a rearward station for a body and canard-type control-surface combination at a Mach number of 2.0, at angles of attack from 0° to 6° and control-deflection angles from 0° to $9\text{-}1/2^\circ$. The effects of the trailing vortices on the flow field adjacent to the body are presented.

NACA RM E52K07

COMPARISON OF PRESSURE-LOSS CHARACTERISTICS OF SEVERAL TAIL-CONE AIR-INDUCTION SYSTEMS FOR AIR-COOLED GAS-TURBINE ROTORS. Gordon T. Smith and Arthur N. Curren. January 1953. 52p. diagrs., tab. (NACA RM E52K07)

Three configurations for introducing cooling air through a turbojet engine tail cone to a cooled turbine rotor were investigated by use of scale-model systems, and the pressure-loss characteristics of one model system were compared to a similar full-scale system. The effects of the pressure losses in the cooling-air-induction system on the sea-level and altitude performance of a turbojet engine were evaluated, and the design compromises between an aerodynamically refined and a mechanically simple air-induction system were discussed.

NACA RM E52K20

IGNITION DELAYS OF SOME NONAROMATIC FUELS WITH LOW-FREEZING RED FUMING NITRIC ACID IN TEMPERATURE RANGE -40° TO -105° F. Riley O. Miller. January 1953. 17p. diagrs., tabs. (NACA RM E52K20)

Ignition-delay experiments were conducted in a modified open-cup apparatus with a low-freezing red fuming nitric acid. Data indicate that allylamine, mixed alkyl thiophosphites and ethylenimine can be diluted with as much as 70 percent triethylamine and ignite with average delays of approximately 41 milliseconds or less at -76° F. Ethylenimine diluted with 50 percent n-heptane ignited with average delays of 60 and 104 milliseconds, respectively, at -40 and -105° F. Blends of 50-percent allylamine in triethylamine and 50 percent ethylenimine in triethylamine gave average delays of 50 and 33 milliseconds, respectively, at -105° F (acid supercooled).

NACA RM E52K25

IGNITION DELAYS OF ALKYL THIOPHOSPHITES WITH WHITE AND RED FUMING NITRIC ACIDS WITHIN TEMPERATURE RANGE 80° TO -105° F. Riley O. Miller and Dezso J. Ladanyi. February 1953. 24p. diagrs., photo., tabs. (NACA RM E52K25)

Ignition delays of alkyl thiophosphites were obtained in a modified open-cup apparatus and a small-scale rocket engine apparatus. At -40° F, mixed alkyl thiophosphites gave short delays with white fuming nitric acid containing 2 percent water and red fuming nitric acids of widely varying compositions. At -40° F and higher, triethyl trithiophosphite blended with as much as 40 percent n-heptane gave satisfactory ignition delays. With suitable acid, mixed alkyl thiophosphites have satisfactory self-igniting properties at temperatures as low as -76° F.

NACA RM E53I02

EVALUATION OF ETHYL ETHER AS AN IGNITION AID FOR TURBOJET ENGINE FUELS. Edmund R. Jonash and Hampton H. Foster. October 1953. 11p. diagrs., tab. (NACA RM E53I02)

An investigation was conducted to determine the effectiveness of ethyl ether as an ignition aid for low volatility turbojet engine fuels. The minimum spark energies required to ignite a single J33 combustor over a range of altitude inlet-air pressures and flow rates were obtained with a low-volatility reference fuel and with reference fuel blends containing (1) 10 percent ethyl ether, and (2) 10 percent normal pentane. Results indicated that the addition of ethyl ether improved the ignition characteristics of the low-volatility (1 lb RVP) fuel significantly; however, similar improvements in ignition were obtained with the addition of normal pentane in the same concentration. The improvement in ignition characteristics was, therefore, attributed solely to the increase in the front-end volatility characteristics of the reference fuel. The observed trend substantiates the results of previous investigations of the effect of fuel volatility on ignition characteristics.

NACA RM E54K17

PERFORMANCE OF AS-FORGED, HEAT-TREATED, AND OVERAGED S-816 BLADES IN A TURBOJET ENGINE. J. W. Weeton, F. J. Clauss, and J. R. Johnston. March 1955. 51p. diagrs., photos., tabs. (NACA RM E54K17)

From an investigation of several heat treatments on the operating life of S-816 turbine blades, an as-forged group of blades and a group aged without prior solution treatment performed twice as well as a group given the standard AMS heat treatment for S-816 and performed better than all other heat-treated groups. This superior performance was associated with a high hardness and a dense and uniform precipitation of carbides throughout the microstructure. Double aging the blades subsequent to solution treating and solution treating at high temperatures reduced the engine life of the blades. A low-temperature overaging of 16 hours at 1550° F was very damaging to blade performance, while a high-temperature overaging of 16 hours at 1950° F was not damaging.

NACA RM E54K23

AN EXPERIMENTAL EVALUATION OF SEVERAL DESIGN VARIATIONS OF HOLLOW TURBINE BLADES FOR EXPENDABLE ENGINE APPLICATION. W. C. Morgan and R. H. Kemp. February 1955. 33p. diagr., photos., tabs. (NACA RM E54K23)

An investigation was made to evaluate several design variations of hollow turbine blades intended for missile engine use. In one general type, the airfoils were formed from sheet metal; in a second type, the blades were cast. The blades were operated in a J47 engine at 7950 rpm turbine speed and 1260° F tailpipe temperature until a failure occurred or a service life of 30 hours had been attained. It was determined that a practical missile turbine blade can be made by either method of fabrication. In addition, useful data were obtained on root fastenings for application to light-weight rotors.

NACA RM E55L12a

USE OF MEAN-SECTION BOUNDARY-LAYER PARAMETERS IN PREDICTING THREE-DIMENSIONAL TURBINE STATOR LOSSES. Warner L. Stewart, Warren J. Whitney, and Robert Y. Wong. March 1956. 21p. diagrs. (NACA RM E55L12a)

A method is developed for using stator mean-section boundary-layer parameters in predicting three-dimensional stator losses. This method is applied to a highly loaded stator for critical velocity ratios ranging from approximately 0.5 to 1.2. These theoretical results are compared with the results obtained from two complete annular surveys of the stator. On the basis of these limited data, the method appears satisfactory for predicting three-dimensional stator losses, even though the effects of secondary flows are not considered.

NACA RM L7I26

FLIGHT-TEST EVALUATION OF THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF 0.5-SCALE MODELS OF THE LARK PILOTLESS-AIRCRAFT CONFIGURATION. David G. Stone. February 6, 1948. 60p. diagrs., photos., tabs. (NACA RM L7I26)

Longitudinal stability and control characteristics of 0.5-scale models of the Lark pilotless aircraft were investigated in flight for the standard configuration with horizontal wing flaps deflected 0°, 15°, 60°, and for a configuration with tail surfaces in line with the wings with wing flaps undeflected. Results are presented concerning static and dynamic longitudinal stability and control effectiveness characteristics.

NACA RM L50F21

THE ROLLING EFFECTIVENESS OF WING-TIP AILERONS AS DETERMINED BY ROCKET-POWERED TEST VEHICLES AND LINEAR SUPERSONIC THEORY. Carl A. Sandahl, H. Kurt Strass, and Robert O. Piland. Appendix: DETERMINATION OF THE THEORETICAL ROLLING EFFECTIVENESS OF WING-TIP AILERONS. Robert O. Piland. August 29, 1950. 32p. diagrs., photo., tab. (NACA RM L50F21)

The rolling effectiveness and drag of half-delta wing-tip ailerons on rectangular and tapered wings swept back 0° and 45° have been determined by means of rocket-powered test vehicles. The results are compared with those for plain partial-span ailerons and linear supersonic theory.

NACA RM L50G31

FLIGHT INVESTIGATION AT MACH NUMBERS FROM 0.8 TO 1.4 TO DETERMINE THE ZERO-LIFT DRAG OF WINGS WITH "M" AND "W" PLAN FORMS. Ellis Katz, Edward T. Marley, and William B. Pepper. September 18, 1950. 23p. diagrs., photos., tab. (NACA RM L50G31)

The zero-lift drag of wings having "M" and "W" plan forms has been measured in rocket model flight tests at Mach numbers from 0.8 to 1.4. The results are compared with the drag of wings having conventional rectangular and sweptback plan forms. Measurements of bending and torsional deflections for the test wings were made and are presented for comparison with sweptback wings.

NACA RM L50H04

FLIGHT MEASUREMENTS OF THE PRESSURE DISTRIBUTION ON THE WING OF THE X-1 AIRPLANE (10-PERCENT-THICK WING) OVER A CHORDWISE STATION NEAR THE MIDSPAN, IN LEVEL FLIGHT AT MACH NUMBERS FROM 0.79 TO 1.00 AND IN A PULL-UP AT A MACH NUMBER OF 0.96.
H. Arthur Carner and Ronald J. Knapp.
September 12, 1950. 25p. diagrs., photo., tab.
(NACA RM L50H04)

Presents results of flight measurements of the chordwise pressure distribution over a section at 64.4 percent semispan on the left wing of the X-1 airplane with 10-percent-thick wing. The data cover a Mach number range from 0.79 to 1.00 for a section normal-force coefficient of 0.32 and a section normal-force-coefficient range from 0.34 to 1.00 at a Mach number of 0.96.

NACA RM L50H25

TABULATED PRESSURE COEFFICIENTS AND AERODYNAMIC CHARACTERISTICS MEASURED ON THE WING OF THE BELL X-1 AIRPLANE IN LEVEL FLIGHT AT MACH NUMBERS FROM 0.79 TO 1.00 AND IN A PULL-UP AT A MACH NUMBER OF 0.96.
H. Arthur Carner and Mary M. Payne.
September 18, 1950. 43p. diagrs., photo., tabs.
(NACA RM L50H25)

Presents tabulated pressure coefficients and aerodynamic characteristics measured on the left wing of the Bell X-1 airplane in a level run at Mach numbers from 0.79 to 1.00 and in a pull-up to an airplane normal-force coefficient of 0.91 at a Mach number of approximately 0.96.

NACA RM L50H25a

A SMALL-SCALE INVESTIGATION OF "M" AND "W" WINGS AT TRANSONIC SPEEDS. George S. Campbell and William D. Morrison, Jr. October 2, 1950. 30p. diagrs., photo., tab.
(NACA RM L50H25a)

An aerodynamic investigation has been conducted in the Langley high-speed 7- by 10-foot tunnel in order to compare the characteristics of wings of "M" and "W" plan forms with those of a wing having conventional sweepback. Three semispan wings were investigated at Mach numbers from 0.60 to 1.08 at Reynolds numbers of the order of 600,000. The wings were of aspect ratio 6 and taper ratio 0.6 and had NACA 65A009 airfoil sections; the quarter-chord lines were swept 45°. In addition to the lift, drag, pitching-moment, and bending-moment data, changes in local wing incidence measured under simulated air loads are presented. Theoretical span loadings were calculated at a Mach number of 0.70.

NACA RM L51E10a

AERODYNAMIC CHARACTERISTICS OF WINGS DESIGNED FOR STRUCTURAL IMPROVEMENTS.
Joseph Weil and Edward C. Polhamus. May 28, 1951.
12p. diagrs. (NACA RM L51E10a)

A brief review of the effects of wing thickness and thickness distribution of the high-speed aerodynamic and structural characteristics of a representative swept-wing configuration is presented. The aerodynamic information available on several composite plan-form wings is also summarized.

NACA RM L51F25

TABULATED PRESSURE COEFFICIENTS AND AERODYNAMIC CHARACTERISTICS MEASURED ON THE WING OF THE BELL X-1 AIRPLANE IN AN UNACCELERATED LOW-SPEED STALL, IN PUSH-OVERS AT MACH NUMBERS OF 0.83 AND 0.99, AND IN A PULL-UP AT A MACH NUMBER OF 1.16.
Ronald J. Knapp. September 1951. 53p. diagrs., photo., tabs. (NACA RM L51F25)

Presents tabulated pressure coefficients and aerodynamic characteristics measured on the wing of the Bell X-1 research airplane in an unaccelerated low-speed stall, in push-overs at Mach numbers of 0.83 and 0.99, and in a pull-up at a Mach number of 1.16.

NACA RM L51K16

FREE-FLIGHT MEASUREMENTS OF SOME EFFECTS OF AILERON SPAN, CHORD, AND DEFLECTION AND OF WING FLEXIBILITY ON THE ROLLING EFFECTIVENESS OF AILERONS ON SWEPTBACK WINGS AT MACH NUMBERS BETWEEN 0.8 AND 1.6. Eugene D. Schult, H. Kurt Strass, and E. M. Fields. January 1952.
52p. diagrs., photos., tabs. (NACA RM L51K16)

As part of the NACA transonic research program some free-flight measurements were made over a Mach number range of 0.8 to 1.6 to determine some effects of aileron span, chord, and deflection on the rolling effectiveness of constant-percent-chord ailerons on wings with quarter-chord lines swept back 35° and 45°, aspect ratios of 4, taper ratios of 0.6, and NACA 65A006 airfoil sections. All data were corrected for aeroelastic effects of wing twist.

NACA RM L52E14a

TRANSONIC AERODYNAMIC CHARACTERISTICS OF THREE W-PLAN-FORM WINGS HAVING ASPECT RATIO 8, TAPER RATIO 0.45, AND NACA 63A-SERIES AIRFOIL SECTIONS. William D. Morrison, Jr. July 1952. 30p. diagrs., photo.
(NACA RM L52E14a)

The transonic aerodynamic characteristics of three W-plan-form wings having NACA 63A-series airfoil sections, aspect ratio 8, and taper ratio 0.45 have been determined by a reflection-plane technique over a Mach number range from 0.70 to 1.09 at Reynolds numbers of the order of 500,000. A 35° wing and one 45° wing had thickness ratios tapered from 0.10 at the root to 0.06 at the tip. The other 45° wing had a constant thickness ratio of 0.12. Comparisons were made to determine the effects on the aerodynamic characteristics of plan-form modifications, thickness, and sweep variation.

NACA RM L52F11

PRESSURE DISTRIBUTION AT LOW SPEED ON A MODEL INCORPORATING A W WING WITH ASPECT RATIO 6, 45° SWEEP, TAPER RATIO 0.6, AND AN NACA 65A009 AIRFOIL SECTION. Edward C. Polhamus and Albert G. Few, Jr. August 1952. 46p. diagrs., photo. (NACA RM L52F11)

An investigation of low-speed pressure distributions was conducted on a wing-fuselage configuration having a wing of W plan form with aspect ratio 6, 45° sweep, taper ratio 0.6, and an NACA 65A009 airfoil section placed parallel to the plane of symmetry. Wake surveys at several angles of attack for various spanwise positions and stall patterns obtained from tuft studies on the wing for several angles of attack are also presented.

NACA RM L52J21

STATIC AEROELASTIC PHENOMENA OF M-, W-, AND Λ-WINGS. Franklin W. Diederich and Kenneth A. Foss. February 1953. ii, 111p. diagrs., tabs. (NACA RM L52J21)

Some static aeroelastic calculations have been made for nine M-, W-, and Λ-wings, and some qualitative conclusions are drawn concerning the plan forms most suitable from an aeroelastic point of view.

NACA RM L52K04

TRANSONIC CHARACTERISTICS OF A 45° SWEPTBACK WING-FUSELAGE COMBINATION. EFFECT OF LONGITUDINAL WING POSITION AND DIVISION OF WING AND FUSELAGE FORCES AND MOMENTS. Joseph M. Hallissy and Donald R. Bowman. February 1953. 39p. diagrs., photo. (NACA RM L52K04)

Lift, drag, and pitching-moment data were obtained in the Langley 16-foot transonic tunnel on a 45° sweptback wing-fuselage combination with the wing mounted at the maximum fuselage diameter and 1.2 chords aft of the maximum diameter. In the forward wing position data were obtained on the wing in the presence of the fuselage as well as on the complete configuration. The Reynolds number was 5.5×10^6; the angle-of-attack range varied from -2° to 26° at the lowest Mach number (0.6) to -2° to 8° at the highest Mach number (1.03).

NACA RM L52K04a

ROCKET-MODEL INVESTIGATION OF LONGITUDINAL STABILITY AND DRAG CHARACTERISTICS OF AN AIRPLANE CONFIGURATION HAVING A 60° DELTA WING AND A HIGH UNSWEPT HORIZONTAL TAIL. Robert F. Peck and Jesse L. Mitchell. January 1953. 28p. diagrs., photo. (NACA RM L52K04a)

A rocket-propelled model was flown to investigate the longitudinal stability and drag characteristics of an airplane configuration having a 60° delta wing with an NACA 65A003 airfoil section and a high unswept horizontal tail. Data are presented for a Mach number range between 0.90 and 1.37. Comparisons were made with data from similar configurations.

NACA RM L52K06a

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF WING INCIDENCE ANGLE ON THE CHARACTERISTICS OF TWO WING-BODY COMBINATIONS. Francis G. Morgan, Jr. January 1953. 28p. diagrs., photo. (NACA RM L52K06a)

Two wing-body combinations, one with a 45° sweptback wing and one with an unswept wing, were tested at angles of incidence of 4° and 3°, respectively. The first wing has 45° sweepback of the 0.25-chord line, an aspect ratio of 4, a taper ratio of 0.6, and NACA 65A006 airfoil sections parallel to the model plane of symmetry. The other wing has zero sweep of the 0.25-chord line, an aspect ratio 4, and a taper ratio of zero. The streamwise sections of the wing are symmetrical, and consist of circular arcs with the maximum thickness of 0.04 chord located at the 0.40-chord stations. Lift, drag, pitching moment, and base pressures were measured. The effect of wing incidence on aerodynamic characteristics is discussed.

NACA RM L52K12a

TRANSONIC WIND-TUNNEL INVESTIGATION OF AN UNSWEPT WING IN COMBINATION WITH A SYSTEMATIC SERIES OF FOUR BODIES. Bruce B. Estabrooks. January 1953. 25p. diagrs., photos. (NACA RM L52K12a)

An investigation was conducted in the Langley 8-foot transonic tunnel of the interference effects between an unswept wing and a systematic series of bodies at Mach numbers from 0.60 to 1.13. The wing had 0° sweepback of the 0.25-chord line, an aspect ratio of 4, a taper ratio of 0, and 4-percent-thick, symmetrical airfoil sections parallel to the plane of symmetry. The airfoil sections consisted of circular arcs with the maximum thickness at the 0.40-chord station. The wing-body interference effects on the aerodynamic characteristics were most pronounced in the transonic speed range, and the drag was most significantly affected. At low lift coefficients, the drag rise associated with the increase in Mach number to 1.00 was reduced by 20 to 30 percent by replacing the curved afterbody of the basic model with a cylindrical afterbody.

NACA RM L52K13

SMALL-SCALE TRANSONIC INVESTIGATION OF A 45° SWEPTBACK WING OF ASPECT RATIO 4 WITH COMBINATIONS OF NOSE-FLAP DEFLECTIONS AND WING TWIST. William J. Alford, Jr., and Kenneth P. Spreemann. January 1953. 23p. diagrs., photo. (NACA RM L52K13)

A small-scale transonic investigation of a semispan wing swept back 45° and of aspect ratio 4 with combinations of nose-flap deflections and wing twist was made in the Langley high-speed 7- by 10-foot tunnel over a Mach number range from 0.60 to 1.11. Results are presented of the wing-alone configurations of the basic wing and modifications that consisted of a 6° nose-flap deflection in combination with 0°, 3.3°, and 6.5° washout. Lift, drag, and pitching-moment data were obtained for these configurations.

NACA RM L52K14

INITIAL FLUTTER TESTS IN THE LANGLEY TRANSONIC BLOWDOWN TUNNEL AND COMPARISON WITH FREE-FLIGHT FLUTTER RESULTS. William J. Bursnall. January 1953. 19p. diagrs., photos., tabs. (NACA RM L52K14)

An experimental wing-flutter investigation was conducted in the Langley transonic blowdown tunnel, which is equipped with a slotted test section, in order to determine the correlation between transonic wind-tunnel and free-fall flight flutter results. Excellent agreement between wind-tunnel and flight flutter tests shows the feasibility of conducting flutter tests in transonic wind tunnels with slotted test sections.

NACA RM L52K14b

FLIGHT INVESTIGATION OF A SUPERSONIC CANARD MISSILE EQUIPPED WITH AN AUXILIARY DAMPING-IN-PITCH CONTROL SYSTEM. Martin T. Moul. February 1953. 31p. diagrs., photos., tabs. (NACA RM L52K14b)

A canard missile equipped with a rate-gyro—servo control system acting through wing-tip controls to provide auxiliary damping in pitch was flight-tested at Mach numbers of 0.70 to 1.85. The rate system was effective in damping longitudinal transient responses, produced by a continuous square-wave deflection of canard fins, at all Mach numbers.

NACA RM L52K18

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE CHARACTERISTICS OF A TWISTED AND CAMBERED 45° SWEPTBACK WING-FUSELAGE CONFIGURATION. Daniel E. Harrison. December 1952. 20p. diagrs. (NACA RM L52K18)

An investigation was made in the Langley 8-foot transonic tunnel to determine effects of twist and camber on the aerodynamic characteristics of a 45° sweptback wing-fuselage configuration at transonic speeds. The wing was twisted and cambered to obtain uniform load distribution at $M = 1.2$ and $C_L = 0.4$. The wing had 45° sweepback, aspect ratio 4, taper ratio 0.6, and NACA 65A-series airfoil sections with 6-percent-thickness distribution parallel to the plane of symmetry. Lift, drag, and pitching-moment results are presented at Mach numbers from 0.80 to 1.10 and Reynolds numbers based on the mean aerodynamic chord from 1.91×10^6 to 1.99×10^6.

NACA RM L52L01

FLIGHT MEASUREMENTS OF PRESSURES ON BASE AND REAR PART OF FUSELAGE OF THE BELL X-1 RESEARCH AIRPLANE AT TRANSONIC SPEEDS, INCLUDING POWER EFFECTS. Ronald J. Knapp and Wallace E. Johnson. January 1953. 31p. diagrs., photos. (NACA RM L52L01)

Flight measurements of the pressure distribution over the base and rear portion of fuselage of the Bell X-1 rocket-propelled airplane at transonic speeds, including power effects, are presented.

NACA RM L53D20

FLIGHT-DETERMINED PRESSURE DISTRIBUTIONS OVER THE WING OF THE BELL X-1 RESEARCH AIRPLANE (10-PERCENT-THICK WING) AT SUBSONIC AND TRANSONIC SPEEDS. Ronald J. Knapp and Gareth H. Jordan. June 1953. 43p. diagrs., photo., tab. (NACA RM L53D20)

Aerodynamic section characteristics for various span locations, as determined by pressure-distribution measurements in flight to high lift at Mach numbers between 0.30 and 1.19, are presented for the 10-percent-thick wing of the Bell X-1 research airplane.

NACA RM L53F22

TRANSONIC AERODYNAMIC CHARACTERISTICS IN PITCH OF A W-WING HAVING 60° 48' PANEL SWEEP, ASPECT RATIO 3.5, AND TAPER RATIO 0.25. William D. Morrison, Jr. August 1953. 18p. diagrs., photo. (NACA RM L53F22)

The transonic aerodynamic characteristics in pitch of a W-wing having 60° 48' panel sweep, aspect ratio 3.5, and taper ratio 0.25 have been determined by a reflection-plane technique over a Mach number range from 0.70 to 1.10 at Reynolds numbers of the order of 850,000. Limited comparisons are made with swept-wing data to determine the effect on the various aerodynamic parameters of the plan-form modification.

NACA RM L53F30

HORIZONTAL-TAIL LOAD MEASUREMENTS AT TRANSONIC SPEEDS OF THE BELL X-1 RESEARCH AIRPLANE. John T. Rogers. September 1953. 23p. diagrs., photo., tab. (NACA RM L53F30)

Flight measurements of aerodynamic tail loads have been made on the Bell X-1 research airplane from which the balancing tail loads, the static-longitudinal-stability parameter $(dC_m/dC_L)_{WF}$, wing-fuselage aerodynamic center, and zero-lift wing-fuselage combination pitching-moment coefficient have been determined from a Mach number of 0.7 to a Mach number greater than 1.0. A comparison was made of measured tail loads and loads calculated using available wind-tunnel data.

NACA RM L53G14

WING LOADS ON THE BELL X-1 RESEARCH AIRPLANE (10-PERCENT-THICK WING) AS DETERMINED BY PRESSURE-DISTRIBUTION MEASUREMENTS IN FLIGHT AT SUBSONIC AND TRANSONIC SPEEDS. Ronald J. Knapp and Gareth H. Jordan. November 1953. 35p. diagrs., photo., tab. (NACA RM L53G14)

The wing loads (including some wing-to-fuselage load carry over) and some aerodynamic characteristics as determined by pressure-distribution measurements in flight to high lift at Mach numbers from 0.50 to 1.19 for the 10-percent-thick wing of the Bell X-1 research airplane are presented.

NACA RM L53I15

FUSELAGE PRESSURES MEASURED ON THE BELL X-1 RESEARCH AIRPLANE IN TRANSONIC FLIGHT. Ronald J. Knapp, Gareth H. Jordan, and Wallace E. Johnson. November 1953. 21p. diagrs., photo. (NACA RM L53I15)

Fuselage pressure distributions and integrated normal load on the fuselage of the Bell X-1 research airplane (10-percent-thick wing) in flight during pull-ups to near maximum lift at Mach numbers of about 0.78, 0.85, 0.88, and 1.02 are presented.

NACA RM L53J02a

AERODYNAMIC CHARACTERISTICS IN PITCH OF THREE STRUCTURALLY SIMILAR FLEXIBLE WINGS WITH 45° SWEEP: A SWEPTBACK WING, A WING WITH M PLAN FORM, AND A WING WITH W PLAN FORM. John W. McKee, Delwin R. Croom, and Rodger L. Naeseth. December 1953. 43p. diagrs., photos. (NACA RM L53J02a)

An investigation has been made in the Langley 300-MPH 7- by 10-foot tunnel to determine the aerodynamic characteristics in pitch of three structurally similar flexible wings with 45° of sweep of the quarter-chord line: a sweptback wing, a wing with M plan form, and a wing with W plan form. In addition, a rigid sweptback wing was tested. The wings were of aspect ratio 6 and taper ratio 0.6, and had NACA 65A009 airfoil sections parallel to the free airstream direction. The semispan wings were tested through a dynamic pressure range of approximately 4.7 to 46 pounds per square foot. The variation of Reynolds number was from approximately 0.4×10^6 to 1.25×10^6. In addition to lift, drag, pitching-moment, and bending-moment data, wing deflection and twist angles under air load were measured and flow surveys were made behind the wings. The effects of change of plan form from straight sweep to a change of sweep at midsemispan and the large degree of flexibility provided in the models combined to produce some pronounced effects on wing deflection and aerodynamic characteristics. The data are examined on the basis of constant dynamic pressure and on the basis of constant wing loading. The results of theoretical calculations are compared with the experimental results.

NACA RM L53K03a

THE TWISTING EFFECT AT TRANSONIC SPEEDS OF SPOILER AILERONS ON A 45° SWEPTBACK, ASPECT-RATIO-4, TAPERED WING. Alexander D. Hammond and Jean C. Graven, Jr. January 1954. 21p. diagrs., photo. (NACA RM L53K03a)

Results and discussion of the twisting moment and other aerodynamic characteristics resulting from projection of various-span inboard spoiler ailerons on a 45° sweptback, aspect-ratio-4, taper-ratio-0.6 wing from a Mach number of 0.61 to 1.09 are presented. Incremental lift, drag, pitching-moment, and twisting-moment coefficients, and rolling-moment and yawing-moment coefficients are presented for various inboard spoiler spans at angles of attack from -5° to 10°.

NACA RM L53K09

MEASURED AND ESTIMATED LATERAL STATIC AND ROTARY DERIVATIVES OF A 1/12-SCALE MODEL OF A HIGH-SPEED FIGHTER AIRPLANE WITH UNSWEPT WINGS. James L. Williams. January 1954. 24p. diagrs., photos., tab. (NACA RM L53K09)

Lateral static and rotary derivatives experimentally determined at low speed in the Langley stability tunnel for a model of a high-speed fighter airplane with unswept wings are presented in this paper. A comparison of the measured and estimated derivatives at three angles of attack is also presented, along with data on the effect of fuselage afterbody shape on the static lateral stability derivatives.

NACA RM L53K10

EFFECT ON TRANSONIC AND SUPERSONIC DRAG OF A FUSELAGE PROTUBERANCE DESIGNED TO IMPROVE THE AREA DISTRIBUTION OF AN ESSENTIALLY UNSWEPT WING-FUSELAGE COMBINATION. Carl A. Sandahl. January 1954. 10p. diagrs., photos., tab. (NACA RM L53K10)

An investigation was made to determine the effect on transonic and supersonic drag of a fuselage protuberance designed to improve the overall longitudinal distribution of cross-sectional area of an essentially unswept wing-fuselage configuration. The protuberance had no effect on drag at Mach numbers up to 1; at higher Mach numbers the protuberance increased the drag.

NACA RM L53K20

FLIGHT INVESTIGATION OF THE ROLLING EFFECTIVENESS OF FINGERED SEMAPHORE SPOILERS ON A TAPERED 45° SWEPTBACK WING BETWEEN MACH NUMBERS 0.6 AND 1.3. James D. Church. January 1954. 27p. diagrs., photos. (NACA RM L53K20)

By using rocket models in free flight, some effects of spoiler projection and chordwise position on rolling effectiveness and drag were determined for a fingered semaphore spoiler and a solid spoiler configuration between Mach numbers 0.6 and 1.3. The test wing was swept back 45° along the quarter-chord line, had an aspect ratio of 3.56, a taper ratio of 0.30, NACA 64A007 airfoil sections, and a solid or fingered spoiler located along a line of constant wing thickness. Wing damping in roll and some effects of roll helix angle on spoiler rolling-moment coefficient were found. Comparisons are made with theory and other rocket-model results.

NACA RM L54C19

LATERAL CONTROL CHARACTERISTICS OF TWO STRUCTURALLY SIMILAR FLEXIBLE WINGS WITH 45° SWEEP: A SWEPTBACK WING AND A WING WITH M PLAN FORM. Rodger L. Naeseth, Delwin R. Croom, and John W. McKee. April 1954. 44p. diagrs., photo., tabs. (NACA RM L54C19)

A low-speed wind-tunnel investigation was made to determine the static lateral control characteristics of flap-type and spoiler-type ailerons on a rigid

sweptback wing, a flexible sweptback wing, and a flexible M-wing. A few tests were also made with a half-delta tip control on the flexible sweptback wing. The wings were of aspect ratio 6.0, taper ratio of 0.6, and had NACA 65A009 airfoil sections parallel to the free-stream direction. The quarter-chord lines of the wings were swept 45°. At low angles of attack, both types of control lost effectiveness with increase in dynamic pressure on the flexible wings. Spoilers, however, tended to maintain a greater percent of rigid-wing control effectiveness; an inboard control location was better than a location near the tip, and controls on the M-wing maintained effectiveness better than those on the swept wing.

NACA RM L54F29

ASPECTS OF INTERNAL-FLOW-SYSTEM DESIGN FOR HELICOPTER PROPULSIVE UNITS. John R. Henry. September 1954. 24p. diagrs. (NACA RM L54F29)

Pertinent items relating to the design of internal-flow systems for reciprocating engine, turbine engine, and pressure-jet installations in helicopters are discussed. The importance of the following items is emphasized: controllable exit and ram recovery for reciprocating-engine cooling; performance penalties possible in turbine-engine installations attributed to distortions in the flow distribution at the face of the axial compressor; the effects of high subsonic flow velocities on the performance of duct elements; and the effects of centrifugal forces on the flow in a ducted helicopter rotor. Data on the maximum flow capacities of bends are included.

NACA RM L54H11

EXPERIMENTAL INVESTIGATION AT HIGH SUBSONIC SPEEDS TO DETERMINE THE ROLLING-STABILITY DERIVATIVES OF THREE WING-FUSELAGE CONFIGURATIONS. William C. Sleeman, Jr. October 1954. 43p. diagrs. (NACA RM L54H11)

Rolling-stability derivatives are presented for three wing-fuselage configurations over a Mach number range from 0.50 to 0.92 and for angles of attack up to 13°. Two of the wings were of aspect ratio 3 and had quarter-chord sweep angles of 12.53° and 30°. An aspect-ratio-4 wing was tested which had 45° sweepback. The range of Reynolds number encountered in tests of these wings was approximately from 2.0×10^6 to 4.0×10^6.

NACA RM L54K10

THE EFFECT OF BASE BLEED ON THE BASE PRESSURE, LIFT, DRAG, AND PITCHING MOMENT OF A 10-PERCENT-THICK BLUNT-BASE AIRFOIL AT A MACH NUMBER OF 2.72. Jim J. Jones. January 1955. 17p. diagrs., photo. (NACA RM L54K10)

An experimental investigation was made at a Mach number of 2.72 to measure the effect of base bleed on the base pressure, lift, drag, and pitching moment of a 10-percent-thick blunt-base airfoil model. On this model the base bleed was effected by bleeding air through small holes in the lower surface near the trailing edge into the base region. The zero-lift drag was reduced about 6 percent for the maximum value of the ratio of bleed-hole area to base area tested. Above a lift coefficient of about 0.075, an optimum value of this area ratio was found but the decrease in total drag at this optimum point over zero area (no base bleed) was very small.

NACA RM L54K15

AERODYNAMIC LOADING CHARACTERISTICS IN SIDESLIP OF A 45° SWEPTBACK WING WITH AND WITHOUT A FENCE AT HIGH SUBSONIC SPEEDS. Richard E. Kuhn and Andrew L. Byrnes, Jr. January 1955. 40p. diagrs., photo., tab. (NACA RM L54K15)

The effects of sideslip on the aerodynamic loading characteristics of a 45° sweptback wing of aspect ratio 4 in combination with a fuselage, as obtained for pressure-distribution measurements, are presented for the clean wing and for the wing with fences. The tests covered a Mach number range from 0.70 to 0.95, angles of attack up to 24°, and angles of sideslip of 0°, 4°, 8°, and 12°. The results indicate that the variations of root bending moment and the coefficient of rolling moment due to sideslip are, in general, due to variations in normal-force coefficients on the leading and trailing wings rather than to lateral center-of-pressure travel. With the fences installed, the rolling moment due to sideslip remained negative throughout the angle-of-attack range.

NACA RM L54K18

INVESTIGATION OF TWO SHORT ANNULAR DIFFUSER CONFIGURATIONS UTILIZING SUCTION AND INJECTION AS A MEANS OF BOUNDARY-LAYER CONTROL. Stafford W. Wilbur and James T. Higginbotham. January 1955. 43p. diagrs. (NACA RM L54K18)

As part of an extensive subsonic diffuser research program, results are presented of an investigation to determine the performance and the influence of boundary-layer controls (injection and suction) on the performance of a short annular diffuser which corresponded to an equivalent conical expansion angle of 100°. Data are also presented on the above diffuser with a fairing added to the downstream face of the inner body, which produced an equivalent cone angle of 32°. The auxiliary air was varied from approximately 0 to 6 percent of the main stream flow. Pressure surveys were made at the inlet and at two diffuser tailpipe stations which were located at 1/2 and 1 diameter downstream from the 100° diffuser inner body. Both suction and injection proved to be effective controls capable of producing flat velocity distributions.

NACA RM L54K22

THE HYDRODYNAMIC FORCE CHARACTERISTICS OF STREAMLINE BODIES OF REVOLUTION HAVING FINENESS RATIOS OF 6, 9, AND 12 WITH AND WITHOUT CHINE STRIPS. Bernard Weinflash and Rudolph E. Fontana. March 1955. 157p. diagrs., photos., tabs. (NACA RM L54K22)

Hydrodynamic force characteristics are given for three streamline bodies of revolution having fineness ratios of 6, 9, and 12, with and without chine strips and, to a limited extent, with tail cones removed to simulate a fuselage with jet exhaust. The data include hydrodynamic resistance, pitching moment, wetted length, and height of the model above the water surface for a range of trim, load, and speed.

NACA RM L54K23

EFFECTS OF SPANWISE LOCATION OF SWEEP DISCONTINUITY ON THE LOW-SPEED LONGITUDINAL STABILITY CHARACTERISTICS OF A COMPLETE MODEL WITH WINGS OF M AND W PLAN FORM. Paul G. Fournier. January 1955. 44p. diagrs., photo., tab. (NACA RM L54K23)

The present paper presents results of a low-speed investigation to determine the effects of spanwise location of sweep discontinuity on the longitudinal stability characteristics of a complete model with M- or W-wings of aspect ratio 6 and taper ratio 0.6. Included in this investigation is the effect of tail height on the longitudinal stability characteristics. All of the wings tested had $\pm 45^{\circ}$ panel sweep of the quarter-chord lines and NACA 65A009 airfoil sections parallel to the plane of symmetry.

NACA RM L54K26

CALCULATED EFFECTS OF THE LATERAL ACCELERATION DERIVATIVES ON THE DYNAMIC LATERAL STABILITY OF A DELTA-WING AIRPLANE. John P. Campbell and Carroll H. Woodling. January 1955. 22p. diagrs., tabs. (NACA RM L54K26)

Calculations were made to determine the dynamic lateral stability of a 60° delta-wing interceptor airplane with the lateral acceleration derivatives $C_{n_{\dot{\beta}}}$ and $C_{l_{\dot{\beta}}}$ included and neglected. Calculations were made for angles of attack of 10°, 20°, and 30° with the airplane flying at sea level and at an altitude of 50,000 feet.

NACA RM L55D22

EFFECTS OF SPANWISE LOCATION OF SWEEP DISCONTINUITY ON THE LOW-SPEED STATIC LATERAL STABILITY CHARACTERISTICS OF A COMPLETE MODEL WITH WINGS OF M AND W PLAN FORM. Paul G. Fournier. May 1955. 33p. diagrs., photo. (NACA RM L55D22)

Results are presented of a low-speed investigation to determine the effects of spanwise location of sweep discontinuity on the static lateral stability characteristics of a complete model with M- or W-wings of aspect ratio 6 and taper ratio 0.6. All the wings tested had $\pm 45^{\circ}$ panel sweep of the quarter-chord lines and NACA 65A009 airfoil sections parallel to the plane of symmetry.

NACA RM L55J06

LOW-SPEED STATIC STABILITY CHARACTERISTICS OF A COMPLETE MODEL WITH AN M-WING IN MID AND HIGH POSITIONS AND WITH THREE HORIZONTAL-TAIL HEIGHTS. Paul G. Fournier. January 1956. 32p. diagrs. (NACA RM L55J06)

Results are presented of a low-speed investigation to determine the effect of wing height on the static lateral and longitudinal stability characteristics of a complete model having an M-wing in mid and high positions with aspect ratio 6, taper ratio 0.60, NACA 65A009 airfoil sections parallel to plane of symmetry, and $\pm 45^{\circ}$ sweep of the quarter-chord lines. Included in this investigation is the effect of tail height on the longitudinal stability characteristics.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1255

AN ANALYSIS OF THE STABILITY AND ULTIMATE COMPRESSIVE STRENGTH OF SHORT SHEET-STRINGER PANELS WITH SPECIAL REFERENCE TO THE INFLUENCE OF THE RIVETED CONNECTION BETWEEN SHEET AND STRINGER. Joseph W. Semonian and James P. Peterson. 1956. ii, 18p. diagrs., photo., tab. (NACA Rept. 1255. Supersedes TN 3431)

A method of strength analysis of short sheet-stringer panels subjected to compression is presented which takes into account the effect that the riveted attachments between the plate and the stiffeners have on the strength of panels. An analysis of experimental data shows that panel strength is highly influenced by rivet pitch, diameter, and location and that the degree of influence for a given riveting depends on the panel configuration and panel material.

NACA Rept. 1259

SOME POSSIBILITIES OF USING GAS MIXTURES OTHER THAN AIR IN AERODYNAMIC RESEARCH. Dean R. Chapman. 1956. ii, 22p. diagrs., tabs. (NACA Rept. 1259. Supersedes TN 3226)

A study is made of possible uses in compressible-flow research of various gas mixtures having the same specific-heat ratio as air. Such mixtures require low wind-tunnel power and have other possible applications in compressor research and firing-range research. Certain gas mixtures can be concocted which behave at wind-tunnel temperatures dynamically similar to air at flight temperatures.

NACA Rept. 1262

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE EFFECT OF TUNNEL WALLS ON THE FORCES ON AN OSCILLATING AIRFOIL IN TWO-DIMENSIONAL SUBSONIC COMPRESSIBLE FLOW. Harry L. Runyan, Donald S. Woolston, and A. Gerald Rainey. 1956. ii, 21p. diagrs. (NACA Rept. 1262. Supersedes TN 3416)

The integral equation defining the problem of an oscillating wing in a tunnel is treated and is presented in a form adapted to calculations. Application is made to a number of examples to illustrate the influence on the magnitude of wall effects of variations in frequency, Mach number, and ratio of tunnel height to wing semichord. Comparison is made with experimental measurements for several subsonic Mach numbers.

NACA Rept. 1265

A THEORY FOR STABILITY AND BUZZ PULSATION AMPLITUDE IN RAM JETS AND AN EXPERIMENTAL INVESTIGATION INCLUDING SCALE EFFECTS. Robert L. Trimpi. 1956. ii, 24p. diagrs., photos., tabs. (NACA Rept. 1265. Supersedes RM L53G28)

From a theory developed on a quasi-one-dimensional-flow basis, it is found that the stability of the ram jet is dependent upon the instantaneous values of mass flow and total pressure recovery of the supersonic diffuser and immediate neighboring subsonic diffuser. Conditions for stable and unstable flow are presented. The theory developed in the report is in agreement with the experimental data of NACA TN 3506 and NACA RM L50K30. A simple theory for predicting the approximate amplitude of small pressure pulsation in terms of mass-flow decrement from minimum-stable mass flow is developed and found to agree with experiments. Cold-flow tests at a Mach number of 1.94 of ram-jet models having scale factors of 3.15:1 and Reynolds number ratios of 4.75:1 with several supersonic diffuser configurations showed only small variations in performance between geometrically similar models. The conditions at which buzz originated were nearly the same for the same supersonic diffuser (cowling-position angle) configurations in both large- and small-diameter models (both Reynolds numbers). There was no appreciable variation in stability limits of any of the models when the combustion-chamber length was increased by a factor of three. The unsteady-flow performance and wave patterns were also similar when considered on a reduced-frequency basis depending on the relative lengths of the model.

NACA Rept. 1266

CHARTS FOR ESTIMATING PERFORMANCE OF HIGH-PERFORMANCE HELICOPTERS. Alfred Gessow and Robert J. Tapscott. 1956. ii, 33p. diagrs. (NACA Rept. 1266. Supersedes TN 3323; TN 3482)

Theoretically derived charts are presented for use in predicting profile-drag—thrust ratios of rotors having hinged blades with 0°, -8°, or -16° twist.

* AVAILABLE ON LOAN ONLY.
ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

The charts are considered applicable to rotor-operating conditions in which high tip-speed ratios or large rotor angles of attack are encountered; however, they do not include the effects of compressibility. Limit lines showing the conditions of onset of stall are presented, and the effects of blade twist on the stall limits are discussed.

NACA Rept. 1271

ON BOATTAIL BODIES OF REVOLUTION HAVING MINIMUM WAVE DRAG. Keith C. Harder and Conrad Rennemann, Jr. 1956. ii, 9p. diagrs., tab. (NACA Rept. 1271. Supersedes TN 3478)

The problem of determining the shape of slender boattail bodies of revolution for minimum wave drag has been reexamined. It was found that minimum solutions for Ward's slender-body drag equation can exist only for the restricted class of bodies for which the rate of change of cross-sectional area at the base is zero. In order to eliminate this restriction, certain higher order terms must be retained in the drag equation and isoperimetric relations. The minimum problem for the isoperimetric conditions of given length, volume, and base area is treated as an example. According to Ward's drag equation, the resulting body shapes have slightly less drag than those determined by previous investigators.

NACA Rept. 1273

A STUDY OF THE ZERO-LIFT DRAG-RISE CHARACTERISTICS OF WING-BODY COMBINATIONS NEAR THE SPEED OF SOUND. Richard T. Whitcomb. 1956. ii, 22p. diagrs., tabs. (NACA Rept. 1273. Supersedes RM L52H08)

Results are presented which indicate that near the speed of sound the zero-lift drag rise of a low-aspect-ratio thin-wing—body combination is primarily dependent on the axial development of the cross-sectional areas normal to the airstream. Results are also presented of an investigation wherein applications of this concept to the reduction of the drag-rise increments of representative wing-body combinations are made.

NACA TM 1420

ON THE CONTRIBUTION OF TURBULENT BOUNDARY LAYERS TO THE NOISE INSIDE A FUSELAGE. G. M. Corcos and H. W. Liepmann, Douglas Aircraft Company, Inc. December 1956. (iii), 43p. diagrs. (NACA TM 1420)

The concept of attentuation is abandoned and instead the problem is formulated as a sequence of two linear couplings: the turbulent boundary-layer fluctuations excite the fuselage skin in lateral vibrations and the skin vibrations induce sound inside the fuselage. The techniques used are those required to determine the response of linear systems to random forcing functions of several variables. A certain degree of idealization has been resorted to. Thus the boundary layer is assumed locally homogeneous; the fuselage skin is assumed flat, unlined, and free from axial loads; and the "cabin" air is bounded only by the vibrating plate so that only outgoing waves are considered. The results, strictly applicable only to the limiting cases of thin boundary layers, show that the sound pressure intensity is proportional to the square of the free-stream density, the square of cabin air density, and inversely proportional to the first power of the damping constant and to the second power of the plate density. The dependence on free-stream velocity and boundary-layer thickness cannot be given in general without a detailed knowledge of the characteristics of the pressure fluctuations in the boundary layer. For a flat spectrum the noise intensity depends on the fifth power of the velocity and the first power of the boundary-layer thickness. Thus it appears that boundary-layer removal is not an economical means of decreasing cabin noise.

NACA TM 1424

ON THE THEORY OF ANISOTROPIC SHALLOW SHELLS. (K Teorii Anizotropnykh Pologikh Obolochek). S. A. Ambartsumyan. December 1956. 11p. tabs. (NACA TM 1424. Translation from Prikladnaia Matematika i Mekhanika, v. 12, 1948, p. 75-80)

Simultaneous equations for both the stress function and the deflection function of an anisotropic shallow shell are developed and reduced to a single eighth-order equation for each function. The lines of curvature are used as coordinates.

NACA TM 1425

ON THE CALCULATION OF SHALLOW SHELLS. (K Raschetu Pologikh Obolochek). S. A. Ambartsumyan. December 1956. 11p. diagr. (NACA TM 1425. Translation from Prikladnaia Matematika i Mekhanika, v. 11, 1947, p. 527-532)

Two simultaneous equations of V. Z. Vlasov for the stresses and deflections of shallow shells are stated and somewhat simplified for application to the problems of uniform and concentrated loading on a shell bounded by a coordinate rectangle. Numerical results are given. The lines of curvature are used as coordinates.

NACA TM 1426

ON THE THEORY OF THIN SHALLOW SHELLS. (K Teorii Tonkikh Pologikh Obolochek). A. A. Nazarov. December 1956. 7p. (NACA TM 1426. Translation from Prikladnaia Matematika i Mekhanika, v.13, 1949, p.547-550)

The equations for a shallow shell are set up in "almost Cartesian coordinates" using a tensor approach. These equations are then reduced to two simultaneous fourth-order equations for the deflection and a stress function analogous to Airy's.

NACA TN 3737

THE MOTIONS OF ROLLING SYMMETRICAL MISSILES REFERRED TO A BODY-AXIS SYSTEM. Robert L. Nelson. November 1956. 51p. diagrs. (NACA TN 3737)

The linearized equations of motion have been derived for a rolling missile having slight aerodynamic asymmetries. Time histories of rolling-missile motions referred to a body-axis system have been prepared to show the types of missile motions that can be encountered. The motions resulting from a trim change and a pulse-rocket disturbance are shown to be mainly determined by the ratio of rolling velocity to pitching frequency. Finally, the derived equations were used in establishing a technique for the reduction of oscillation data for rolling missiles. It is shown that the aerodynamic derivatives can be obtained from flight data if four accelerations are measured. The method was applied to the results obtained from a flight test of a missile configuration.

NACA TN 3774

PROPOSED INITIATING SYSTEM FOR CRASH-FIRE PREVENTION SYSTEMS. Jacob C. Moser and Dugald O. Black. December 1956. 18p. diagrs. (NACA TN 3774)

The initiating system was designed to meet the requirements of such a system as determined by a study of data obtained from full-scale experimental and accidental airplane crashes. An example of the application of these requirements in the design of an initiating system for a twin-engined piston-powered airplane is given. The system proposed can be designed so that it will act rapidly and so that accidental operation is improbable. In addition, if the system does operate accidentally, catastrophic results are also improbable. This system is selective in that it inerts only those damaged zones where combustibles are spilled. The system can be used on all airplanes whether powered by reciprocating, turboprop, or turbojet engines.

NACA TN 3794

DRAG INTERFERENCE BETWEEN A POINTED CYLINDRICAL BODY AND TRIANGULAR WINGS OF VARIOUS ASPECT RATIOS AT MACH NUMBERS OF 1.50 AND 2.02. Elliott D. Katzen and George E. Kaattari. November 1956. 41p. diagrs., photos., tabs. (NACA TN 3794. Supersedes RM A51C27)

The drag of a body alone, six triangular wings of various aspect ratios, and the combinations were measured at Mach numbers of 1.50 and 2.02 at a Reynolds number of 5.5 million (based on the body length). The experimental drag-interference results were in accordance with calculations based on NACA RM A9E19, 1949, with skin-friction effects taken into account, the interference effect being principally the result of fixing transition on the body by adding a wing.

NACA TN 3795

LIFT AND PITCHING-MOMENT INTERFERENCE BETWEEN A POINTED CYLINDRICAL BODY AND TRIANGULAR WINGS OF VARIOUS ASPECT RATIOS AT MACH NUMBERS OF 1.50 AND 2.02. Jack N. Nielsen, Elliott D. Katzen, and Kenneth K. Tang. December 1956. 49p. diagrs., photos., tabs. (NACA TN 3795. Supersedes RM A50F06)

The lift and pitching-moment characteristics of a body alone, six triangular wings of various aspect ratios, and the combinations were measured at Mach numbers of 1.50 and 2.02 at a Reynolds number of 5.5 million (based on the body length) for angles of attack up to 5.5°. The total lift and pitching-moment interference were determined and compared with theory. The agreement was found to be good.

NACA TN 3796

THEORETICAL LIFT DUE TO WING INCIDENCE OF SLENDER WING-BODY-TAIL COMBINATIONS AT ZERO ANGLE OF ATTACK. Alvin H. Sacks. November 1956. 35p. diagrs. (NACA TN 3796)

The theoretical lift of a cylindrical afterbody at zero angle of attack due to incidence of the wing is calculated by means of slender-body theory. It is assumed that the vortex sheet becomes fully rolled up ahead of the tail, and the vortex paths in the presence of the body are determined analytically. The total lift of a variety of slender wing-body-tail combinations due to wing incidence is also calculated.

NACA TN 3797

SECTION CHARACTERISTICS OF THE NACA 0006 AIRFOIL WITH LEADING-EDGE AND TRAILING-EDGE FLAPS. Bruno J. Gambucci. December 1956. 17p. diagrs., photo., tabs. (NACA TN 3797)

Lift and pitching-moment characteristics of an NACA 0006 airfoil are presented for various deflections of a 0.15-chord leading-edge flap and a 0.30-chord plain trailing-edge flap. Pressure-distribution data are presented in tabular form. The data were obtained at a Mach number of 0.15 and a Reynolds number of 4,500,000.

NACA TN 3817

TWO-DIMENSIONAL LOW-SPEED CASCADE INVESTIGATION OF NACA COMPRESSOR BLADE SECTIONS HAVING A SYSTEMATIC VARIATION IN MEAN-LINE LOADING. John R. Erwin, Melvyn Savage, and James C. Emery. November 1956. 129p. diagrs., tabs. (NACA TN 3817. Supersedes RM L53I30b)

The low-speed cascade performance of the high-speed NACA 65-($C_{l_0}A_2I_{8b}$)10 compressor blade sections has been systematically investigated. Comparative tests of blade sections having widely different loading distributions were also made. These data, in conjunction with previously published cascade data, permit a prediction of design performance for most compressor blade sections since the mean lines tested probably encompass the practical range.

NACA TN 3822

SOME MEASUREMENTS OF AERODYNAMIC FORCES AND MOMENTS AT SUBSONIC SPEEDS ON A WING-TANK CONFIGURATION OSCILLATING IN PITCH ABOUT THE WING MIDCHORD. Sherman A. Clevenson and Sumner A. Leadbetter. December 1956. 37p. diagrs., photo., tab. (NACA TN 3822)

Measurements are presented of the aerodynamic forces and moments acting on a wing-tank configuration, with or without fins, oscillating about the wing-root midchord. The reduced-frequency range was from 0.050 to 0.657, whereas the Mach number and Reynolds number range was from 0.18 to 0.75 and 0.9×10^6 to 9.5×10^6, respectively. Comparisons of the experimental aerodynamic forces and moments and their respective phase angles acting on the wing-tank combination with those acting on the tank alone indicated that the overall lifts and moments were greater when the tank was attached. The forces on the tank alone were compared with those determined by an engine-nacelle theory.

NACA TN 3836

SPREADING CHARACTERISTICS OF A JET EXPANDING FROM CHOKED NOZZLES AT MACH 1.91. Morris D. Rousso and L. Eugene Baughman. December 1956. 27p. diagrs., photos. (NACA TN 3836. Supersedes RM E51L19)

Total-temperature surveys were made to determine the gross spreading of jets expanding from axisymmetric convergent and convergent-divergent nozzles. The nozzles were located in the base of conically boattailed bodies of revolution. Surveys were made between the nozzle exit and a station 8 nozzle diameters downstream of the jet exit for jet pressure ratios from 2.5 to 0.16. The temperature profiles of jets expanding into a supersonic stream are considerably smaller in diameter than the temperature profiles of jets expanding into quiescent air. The effect on the wake of varying afterbody geometry was small.

NACA TN 3839

EXPERIMENTAL DROPLET IMPINGEMENT ON SEVERAL TWO-DIMENSIONAL AIRFOILS WITH THICKNESS RATIOS OF 6 TO 16 PERCENT. Thomas F. Gelder, William H. Smyers, Jr., and Uwe von Glahn. December 1956. 77p. diagrs., photos., tabs. (NACA TN 3839)

The rate and area of cloud droplet impingement on several two-dimensional swept and unswept airfoils were obtained experimentally in the NACA Lewis icing tunnel with a dye-tracer technique. Airfoil thickness ratios of 6 to 16 percent, angles of attack from 0° to 12°, and chord sizes from 13 to 96 inches were included in the study. The results are presented in the form of dimensionless impingement parameters in order to cover a wide range of flight and atmospheric conditions.

NACA TN 3847

FATIGUE-CRACK-PROPAGATION AND RESIDUAL-STATIC-STRENGTH RESULTS ON FULL-SCALE TRANSPORT-AIRPLANE WINGS. Richard E. Whaley, M. J. McGuigan, Jr., and D. F. Bryan. December 1956. 57p. diagrs., photos., tabs. (NACA TN 3847)

Results are presented of fatigue-crack propagation during fatigue tests on the wings of C-46 airplanes. Results are also presented of the residual static strength of these wings after fatigue test. The propagation curves along with an explanation of the crack growth are presented for each wing. Curves also show the trends that occur with changing load levels. The loss in static strength is also shown and is compared with the calculated strength and the results of small specimen tests.

NACA TN 3849

ANALYTICAL DETERMINATION OF THE NATURAL COUPLED FREQUENCIES AND MODE SHAPES AND THE RESPONSE TO OSCILLATING FORCING FUNCTIONS OF TANDEM HELICOPTERS. George W. Brooks and John C. Houbolt. December 1956. 45p. diagrs., tabs. (NACA TN 3849)

A method is presented for calculating the natural coupled frequencies and mode shapes of vertical vibrations of tandem helicopters; certain forced excitations are also considered. Degrees of freedom included are translation, pitching, and bending of the fuselage and the blades, and translation of the engine. Sample calculations show the modes for a given case, and indicate the changes in frequencies which result from variations in the uncoupled fuselage frequency and the Southwell coefficient. Frequency response functions of cockpit deflection for various applied oscillating forces are also given.

NACA TN 3850

EXPERIMENTAL INVESTIGATION ON THE LANGLEY HELICOPTER TEST TOWER OF COMPRESSIBILITY EFFECTS ON A ROTOR HAVING NACA 63_2-015 AIRFOIL SECTIONS. James P. Shivers and Paul J. Carpenter. December 1956. 28p. diagrs., photo. (NACA TN 3850)

An investigation has been conducted on the Langley helicopter test tower to determine experimentally the effects of compressibility on the hovering performance and the blade pitching moments of a helicopter rotor having NACA 63_2-015 airfoil sections. Data are presented for blade tip Mach numbers from 0.31 to 0.71. High-tip-speed performance of the rotor having NACA 63_2-015 airfoil sections is compared with that of a rotor having NACA 23015 airfoil sections.

NACA TN 3851

FAILURE CHARACTERISTICS OF PRESSURIZED STIFFENED CYLINDERS. Roger W. Peters and Norris F. Dow. December 1956. 18p. diagrs., photos., tabs. (NACA TN 3851)

Stiffened cylinders of 2024 and 7075 aluminum alloys, representative of fuselage construction, were tested under internal pressure and cyclic torsion. Fatigue cracks which developed in the skin resulted in both gradual and explosive types of failure. The types of failure depended upon the hoop stress and the structural configuration, and particularly upon the ratio of area in rings to associated skin area. The tests indicated that the 7075 alloy is somewhat more prone to the explosive type of failure.

NACA TN 3852

FLIGHT MEASUREMENTS OF THE VIBRATIONS ENCOUNTERED BY A TANDEM HELICOPTER AND A METHOD FOR MEASURING THE COUPLED RESPONSE IN FLIGHT. John E. Yeates, Jr. December 1956. 28p. diagrs., photo., tab. (NACA TN 3852)

A discussion of flight-test and analysis methods for some selected helicopter vibration studies is presented. The use of a mechanical shaker in flight to determine the structural response is reported. The analysis methods described are based on the determination of the power spectral density of the force and of the response due to the force through use of analog frequency-analysis techniques. Results obtained by these methods are presented to show the coupled response of a helicopter in flight for two different blade configurations. In addition, natural-vibration measurements of some of the more important harmonics of rotor speed are presented for a range of speed and power conditions.

NACA TN 3865

WIND-TUNNEL INVESTIGATION OF JET-AUGMENTED FLAPS ON A RECTANGULAR WING TO HIGH MOMENTUM COEFFICIENTS. Vernard E. Lockwood, Thomas R. Turner, and John M. Riebe. December 1956. 51p. diagrs., tab. (NACA TN 3865)

Results and a discussion are presented of a preliminary investigation of jet flaps made in the 300 mph 7- by 10-foot tunnel on an unswept, untapered wing with an aspect ratio of 8.4 and a thickness of 16.7 percent. The jet flaps consisted of air ejected at velocities ranging from zero to choking through a small gap on the upper surface of the wing, and backward over a rounded trailing edge. The ejected air flowed along the circumference of the round trailing edge by means of the Coanda effect and was separated from the surface by means of wedges at angles of 0°, 28°, 57°, 86°, and 110° with respect to the wing chord line. Results are also presented for a limited number of tests of a jet-augmented plain flap and a jet-augmented trim flap.

NACA TN 3867

WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS IN PITCH OF WING-FUSELAGE COMBINATIONS AT HIGH SUBSONIC SPEEDS. TAPER-RATIO SERIES. Thomas J. King, Jr., and Thomas B. Pasteur, Jr. December 1956. 36p. diagrs., photos., tab. (NACA TN 3867. Supersedes RM L53E20)

Aerodynamic characteristics are presented of wing-fuselage combinations having an aspect ratio of 4, a sweepback angle of 45°, and taper ratios of 0.3, 0.6, and 1.0. The tests covered a Mach number range from 0.4 to 0.95 at Reynolds numbers of 2,000,000 to 3,000,000 and an angle-of-attack range from -2° to 26°. The results indicate at low lift coefficients a reduction in lift-curve slope and a forward movement in aerodynamic center with an increase in taper ratio. Small differences in minimum drag, drag due to lift, and lift-drag ratio resulted from variation in taper ratio for the constant-thickness-ratio wings investigated.

NACA TN 3871

AN INVESTIGATION AT SUBSONIC SPEEDS OF SEVERAL MODIFICATIONS TO THE LEADING-EDGE REGION OF THE NACA 64A010 AIRFOIL SECTION DESIGNED TO INCREASE MAXIMUM LIFT. Ralph L. Maki and Lynn W. Hunton. December 1956. 50p. diagrs., tab. (NACA TN 3871)

Two-dimensional test data at both low and high subsonic speeds are presented for three airfoil sections comprised of three related modifications to the leading-edge region of the NACA 64A010 section designed to improve maximum lift characteristics. Comparisons are made with both the NACA 64A010 section and sections incorporating a distributed type of camber, the NACA $a = 1.0$ mean line.

NACA TN 3884

IGNITION DELAYS AND FLUID PROPERTIES OF SEVERAL FUELS AND NITRIC ACID OXIDANTS IN TEMPERATURE RANGE FROM 70° TO -105° F. Riley O. Miller. December 1956. 32p. diagrs., photos., tabs. (NACA TN 3884. Supersedes RM E51J11)

Out of 17 acids containing various amounts of nitric acid, water, nitrogen tetroxide, sulfuric acid, ammonium nitrate, potassium nitrate, and perchloric acid, red fuming nitric acids containing about 19 percent nitrogen tetroxide and 3 percent water were best for low freezing points and short ignition delays in the NACA open-cup apparatus. Of the 29 fuels studied, several blends of aromatic amines in triethylamine were fluid and gave short delays at -76° F; at very low temperatures 30 percent o-toluidine in triethylamine gave the shortest delays with low-freezing red fuming nitric acid.

NACA TN 3885

INVESTIGATION OF TRANSIENT POOL BOILING DUE TO SUDDEN LARGE POWER SURGE. Robert Cole. December 1956. 44p. diagrs., photos., tabs. (NACA TN 3885)

The transient heat-transfer characteristics of a system composed of a nickel ribbon immersed horizontally in a pool of water were determined at atmospheric pressure for average heat-generation rates of 3, 10, and 20 x 10^5 Btu/(hr)(sq ft), and fluid bulk temperatures from 76° to 203° F. The power surge duration was limited to 30 milliseconds. Analyses show that convective heat transfer in the nonboiling region was negligible within the time limits employed. Comparison was made between determined ribbon temperatures and those occurring had the ribbon been completely insulated. Transient heat-transfer coefficients and critical-heat-flux values are tabulated.

NACA TN 3886

AVERAGE PROPERTIES OF COMPRESSIBLE LAMINAR BOUNDARY LAYER ON FLAT PLATE WITH UNSTEADY FLIGHT VELOCITY. Franklin K. Moore and Simon Ostrach. December 1956. 35p. diagrs., tabs. (NACA TN 3886)

The time-average characteristics of boundary layers over either an insulated or isothermal flat plate in nearly quasi-steady flow are determined. Time averages are found without specifying plate velocity explicitly except that it is positive and has an average value. The time average quasi-steady terms are compared to steady flow values at the corresponding average velocity and the effects of the frequency dependent averages are discussed. The special case of harmonic velocity variation is considered, and it is found that large amplitudes accentuate the importance of the frequency-dependent terms. Oscillating the wall to increase the heat-transfer rate is not advantageous if the power to oscillate the plate is accounted for, unless the Prandtl number is in a certain range.

NACA TN 3887

EFFECT OF CONCENTRATION ON IGNITION DELAYS FOR VARIOUS FUEL-OXYGEN-NITROGEN MIXTURES AT ELEVATED TEMPERATURES. E. Anagnostou, R. S. Brokaw, and J. N. Butler. December 1956. 34p. diagrs. (NACA TN 3887)

Ignition delays for mixtures of ethane, n-butane, isobutane, hydrogen, or propane with oxygen and nitrogen were measured at various temperatures and fuel and oxygen concentrations using a flow system. Ignition delays for all fuels were inversely proportional to fuel concentration to some power between 0.6 and 1.7. They also decreased slightly with increasing oxygen concentration and decreased with increasing temperature. Two experimental procedures were used, and these gave different absolute values for the delay but the trends observed were the same by either method.

NACA TN 3888

SIMPLIFIED METHOD FOR ESTIMATING COMPRESSIBLE LAMINAR HEAT TRANSFER WITH PRESSURE GRADIENT. Eli Reshotko. December 1956. 16p. diagrs. (NACA TN 3888)

An approximation is made in the method of TN 3326 which simplifies the calculation of heat transfer. Good agreement with the method of TN 3326 is expected for isothermal surfaces with adverse and small favorable pressure gradients regardless of surface temperature and also for flow with large favorable pressure gradient over cooled surfaces.

NACA TN 3891

RAPID DETERMINATION OF CORE DIMENSIONS OF CROSSFLOW GAS-TO-GAS HEAT EXCHANGERS. Anthony J. Diaguila and John N. B. Livingood. December 1956. 19p. diagrs., tabs. (NACA TN 3891)

A generalized procedure is presented which permits a rapid determination of the core lengths of crossflow gas-to-gas heat exchangers. The heat capacities of both gases, inlet and exit gas conditions on both sides of the exchanger, and the exchanger core configuration must be known. The calculation procedure is applied to two typical core configurations with identical fluid conditions and to one core configuration with different fluid conditions.

NACA TN 3900

INVESTIGATION OF VERTICAL DRAG AND PERIODIC AIRLOADS ACTING ON FLAT PANELS IN A ROTOR SLIPSTREAM. Robert A. Makofski and George F. Menkick. December 1956. 23p. diagrs., photo. (NACA TN 3900)

Tests have been conducted on the Langley helicopter test tower to determine the vertical drag and pressure distributions on flat panels mounted below a helicopter rotor. Calculations of the vertical drag by use of a strip-analysis procedure outlined in the paper and the assumption of a fully contracted wake agreed well with the experimental results over the range from 0.2 to 0.64 rotor radius beneath the plane of zero flapping. The pressure increase caused by the passage of the blade over the panel is a maximum at about the 0.8 radius spanwise station. At this station, the pressure decreases from 10 times the disk loading per blade at 0.05 radius beneath the rotor plane of zero flapping to one-half of the disk loading per blade at 0.64 radius beneath the plane of zero flapping.

INSPECTION TECHNIQUES APPLIED TO THE METROLOGY OF AERODYNAMIC MODELS. H. T. Hill. January 1956. 22p. diagrs., photos. (RAE Tech.Note ADW 1)

With the increasing speeds of modern aircraft, and the related greater use of high-speed wind tunnels, together with the introduction of the "Free Flight" technique, there is not only a major model production problem, but also a parallel three-dimensional metrology problem. This problem is as divorced from normal inspection procedure as is the manufacture of the models themselves from mass production. This paper gives an appreciation of the problem confronting the metrologist, details of the present inspection methods employed by the Royal Aircraft Establishment, and thoughts on further development to improve the accuracy and speed at which these three-dimensional models can be inspected. There is an urgent need to make models more expeditiously and more accurately and also to measure them more completely and much quicker. Undoubtedly the human element must be replaced as far as possible in this work, and automatic means of measuring must assist the metrologist.

ACCELERATION MEASUREMENTS DURING DROP TESTS. D. A. Webber. July 1956. 15p. diagrs., photos. (RAE Tech.Note Structures 198)

During an extensive drop-testing program on a complete aircraft, four types of accelerometer were fitted. The acceleration readings obtained were compared with each other and with accelerations derived from vertical reactions recorded by strain-gaged platforms beneath the main undercarriages. The relative merits of the four instruments for this special purpose are compared.

SERVICE TRIALS OF TRIPLE-VIEW CAMERA METHOD OF MEASURING VERTICAL VELOCITIES IN LANDING (SEA HORNET Mk.XXI). D. A. Webber. June 1956. 21p. diagrs., photos., tabs. (RAE Tech.Note Structures 194)

Extensive trials of the triple-view camera method for measuring vertical velocity have been made on Sea Hornet Mk.XXI aircraft. Records were taken of airfield dummy deck landings and also of day and night landings on an aircraft carrier. Information was obtained on the landing characteristics of the aircraft and the values of vertical velocity obtained from the triple-view camera records are compared with those from the deck camera records. The type of information which can be obtained by the triple-view camera method is demonstrated. The method is critically reviewed and suggestions for its development are made.

FURTHER EXPERIMENTS ON THE SINTERING OF ZINC OXIDE. J. Hutchings and J. P. Roberts. March 1956. 28p. diagrs. (RAE Met.91)

The sintering of zinc oxide powder pressings in mixtures of oxygen and argon was influenced markedly by the proportions of the two gases present. Some powders sintered more when oxygen preponderated, while others sintered more when argon preponderated. A detailed investigation of powders sintering more in a preponderance of oxygen was made. Oxygen was identified as the gas component affecting the sintering. The behavior in a series of pressures of oxygen alone and of argon alone was observed and interpreted. Prefiring and the duration of previous evacuation both influenced sintering. The permeability of the powder pressings to gases was studied.

OPERATIONAL FORMULAE FOR RESPONSE CALCULATIONS. S. Neumark. June 1956. 65p. diagrs., tabs. (RAE Aero 2570)

The paper presents systematic tables of formulas whose purpose is to facilitate the operational solution of response problems reducible to linear differential equations with constant coefficients and with simple forcing functions. The formulas enable the user to find operational equivalents of a wide class of simple functions and, inversely, to find functional equivalents of a great number of operational expressions, in the most rapid and direct manner. In such a way, it is possible to reduce to a minimum the usual heavy algebraical work involved in response calculations. The tables include only such functions whose operational equivalents are algebraic fractions, but these cover a wide field of practical applications. Operational fractions of the first, second, third, and fourth order are treated in a comprehensive way, so that all possible particular cases are included. Additional tables make it possible to reduce every fraction of fifth or sixth order to a combination of fractions of lower order. The introductory text describes the method of deriving the formulas and explains how to use them in solving response problems. A number of examples are appended which show the advantages of the tables and give solutions of several typical problems.

NACA Rept. 1264

A THERMAL EQUATION FOR FLAME QUENCHING. A. E. Potter, Jr., and A. L. Berlad. 1956. ii, 7p. diagrs., tab. (NACA Rept. 1264. Supersedes TN 3398)

A thermal quenching equation is derived; the equation is essentially an extension of a previously proposed diffusional concept. By proper choice of the rate-controlling chemical reaction, the equation becomes suitable for use with rich as well as lean fuel-air mixtures. The equation was tested, using published quenching-distance data for propane-oxygen-nitrogen flames, which include the effect of oxygen-nitrogen ratio, equivalence ratio, pressure, and initial temperature.

NACA RM E56I11

A BALANCED-PRESSURE SLIDING SEAL FOR TRANSFER OF PRESSURIZED AIR BETWEEN STATIONARY AND ROTATING PARTS. Arthur N. Curren and Reeves P. Cochran. January 1957. 17p. diagrs. (NACA RM E56I11)

A combination sliding-ring and pressure-balancing seal capable of transferring pressurized air from stationary to rotating parts was developed and experimentally investigated at sliding velocities and cooling-air pressures up to 10,000 feet per minute and 38.3 pounds per square inch absolute, respectively. Leakage of cooling air was completely eliminated with an expenditure of balance air less than one-fourth the leakage loss of air from labyrinth seals under the same conditions. Additional cooling of the carbon-base seal rings was required, and the maximum wear rate on the rings was about 0.0005 inch per hour.

NACA RM E56J12

IDENTIFICATION OF FOREIGN OBJECTS DAMAGING COMPRESSOR BLADES IN TURBOJET ENGINES. A. E. Spakowski and J. Graab. January 1957. 12p. photos., tabs. (NACA RM E56J12)

Damage to the compressor blades of turbojet engines due to ingestion of foreign objects is a growing problem, the solution of which has been made more difficult by the large percentage of damaging materials that have remained unknown. A rapid emission spectroscopic method was devised to identify the chemical composition of these foreign objects. Results on laboratory-prepared specimens and blades from damaged engines show that the method can be utilized to determine the nature of the ingested foreign objects.

NACA RM L56I26

MEASUREMENTS OF RUNWAY ROUGHNESS OF FOUR COMMERCIAL AIRPORTS. Dexter M. Potter. January 1957. 86p. diagrs., tabs. (NACA RM L56I26)

Measurements of runway roughness were made on runways at Washington National Airport, New York International Airport, La Guardia Airport, and Logan International Airport, Boston, Mass. This report presents these measurements in the form of tables as well as plots.

NACA TM 1406

ON THE USE OF THE HARMONIC LINEARIZATION METHOD IN THE AUTOMATIC CONTROL THEORY. (K voprosu o primenenii metoda harmonicheskoi linearizatsii v teorii regulirovaniya). E. P. Popov. January 1957. 6p. (NACA TM 1406. Translation from Doklady Akademiia Nauk (SSSR), v.106, no.2, 1956, p.211-214)

This paper considers the use of harmonic linearization as applied to the analysis of nonlinear automatic control systems. This approach, which has been proven in practical engineering applications, involves the replacement of a nonlinear equation by a linear equation. In establishing the method a small parameter is considered which makes it possible to speak with some degree of approximation of the solution of the new equation to that of the given linear equation. Thus, the mathematics of nonlinear mechanics is brought to bear on the problem by explaining and extending the usefulness of automatic control theory and nonlinear systems.

NACA TM 1421

A THEORETICAL INVESTIGATION OF THE DRAG OF GENERALIZED AIRCRAFT CONFIGURATIONS IN SUPERSONIC FLOW. E. W. Graham, P. A. Lagerstrom, R. M. Licher, and B. J. Beane, Douglas Aircraft Company, Inc. January 1957. (iv), 108p. diagrs. (NACA TM 1421)

It seems possible that, in supersonic flight, unconventional arrangements of wings and bodies may offer advantages in the form of drag reduction. It is the purpose of this report to consider the methods for determining the pressure drag for such unconventional configurations, and to consider a few of the possibilities for drag reduction in highly idealized aircraft. The idealized aircraft are defined by distributions of lift and volume in three-dimensional space, and Hayes' method of drag evaluation is the fundamental tool employed. Other methods of drag evaluation are considered also wherever they appear to offer simplifications. The basic singularities such as sources, dipoles, lifting elements, and volume elements are discussed, and some of the useful interrelations between these elements are presented. Hayes' method of drag evaluation is derived in detail starting with the general momentum theorem. In going from planar systems to spatial systems, certain new problems arise and are discussed.

NACA TM 1427

TURBULENCE IN THE WAKE OF A THIN AIRFOIL AT LOW SPEEDS. George S. Campbell, California Institute of Technology. January 1957. 63p. diagrs. (NACA TM 1427)

Experiments have been made to determine the nature of turbulence in the wake of a two-dimensional airfoil at low speeds. The experiments were motivated by the need for data which can be used for analysis of the tail-buffeting problem in aircraft design. Turbulent intensity and power spectra of the velocity fluctuations were measured at a Reynolds number of 1.6×10^5 for several angles of attack. Total-head measurements were also obtained in an attempt to relate steady and fluctuating wake properties. Mean-square downwash was found to have nearly the same dependence on vertical position in the wake as that shown by total-head loss. For this particular wing, turbulent intensity, integrated across the wake, increased roughly as the 3/2 power of the drag coefficient. Power-spectrum measurements indicated a decrease in frequency as wing angle of attack was increased. The average frequency in the wake was proportional to the ratio of mean wake velocity to wake width.

NACA TN 3704

MINIMUM-DRAG DUCTED AND CLOSED THREE-POINT BODY OF REVOLUTION BASED ON LINEARIZED SUPERSONIC THEORY. Hermon M. Parker. December 1956. 20p. diagrs., tab. (NACA TN 3704)

The problem of the three-point body of revolution that has minimum wave drag, based on linearized supersonic-flow theory, has been solved formally without resort to slender-body approximations. The evaluation of the source-distribution function, as well as the body shape, requires numerical procedures. Complete calculations are made for the special case of a closed body with a given section (the third point) at the midbody position. The existence of a corner at the third point is found to be characteristic of a linear-theory solution of the minimum-drag three-point problem. The conclusion is reached that the influence between the forward and rearward portions of a closed body results in a small increase in the radii of the minimum-drag shape.

NACA TN 3814

EFFECTS OF VERTICAL FINS NEAR THE NOSE OF THE FUSELAGE ON THE DIRECTIONAL AND DAMPING-IN-YAW STABILITY DERIVATIVES OF AN AIRPLANE MODEL UNDER STEADY-STATE AND OSCILLATORY CONDITIONS. M. J. Queijo and Evalyn G. Wells. December 1956. 54p. diagrs., photo., tab. (NACA TN 3814)

A wind-tunnel investigation has been made at low speed to determine the effects of vertical fins placed ahead of the vertical tail on the directional stability and damping-in-yaw characteristics of a swept-wing model under steady-state oscillatory conditions. Various sizes of fins were used above and below the fuselage center line. The vertical-tail size also was varied.

NACA TN 3819

BASE PRESSURE AT SUPERSONIC SPEEDS ON TWO-DIMENSIONAL AIRFOILS AND ON BODIES OF REVOLUTION WITH AND WITHOUT FINS HAVING TURBULENT BOUNDARY LAYERS. Eugene S. Love. January 1957. 65p. diagrs., photos. (NACA TN 3819. Supersedes RM L53C02)

An analysis is made of available experimental data to show the effect of most of the variables that are more predominant in determining base pressure at supersonic speeds. The analysis is restricted to turbulent boundary layers and covers two-dimensional bases and the bases of bodies of revolution with and without stabilizing fins. An analogy to the peak pressure rise associated with the separation of the boundary layer is presented as are simple semiempirical methods for the estimation of base pressure.

CURRENT NACA RESEARCH REPORTS

NACA TN 3823

INVESTIGATION OF ROTATING STALL IN A SINGLE-STAGE AXIAL COMPRESSOR. S. R. Montgomery and J. J. Braun, Massachusetts Institute of Technology. January 1957. 28p. diagrs., photos. (NACA TN 3823)

The rotating-stall characteristics of a single-stage axial-flow compressor were investigated. The number of stall cells and their propagation velocities were found with and without stator blades. The measured velocities were compared with those predicted by Stenning's theory (see NACA TN 3580), assuming the downstream pressure fluctuations to be negligible, and correlation within 10 percent was obtained at the onset of stall.

NACA TN 3828

INVESTIGATION OF THE NiAl PHASE OF NICKEL-ALUMINUM ALLOYS. Edward M. Grala. January 1957. 33p. diagrs., photos., tabs. (NACA TN 3828)

The effects of composition and homogenization heat treatments on the room- and elevated-temperature mechanical properties of the cast NiAl intermetallic were determined. Small changes in composition within the NiAl phase field resulted in appreciable strength and hardness changes. Room-temperature hardness of alloys containing 25 to 35 percent aluminum exhibited a sharp minimum at 31.5 percent aluminum (stoichiometric NiAl). Homogenized NiAl specimens had tensile strengths at room temperature ranging from 29,450 psi for the 25-percent-aluminum alloy to 14,900 psi for stoichiometric NiAl. At 1500° F the tensile strength of homogenized alloys ranged from 29,050 psi for the 25-percent-aluminum alloy to 14,500 psi for the stoichiometric alloy. Additions of 0.5 to 2.0 percent molybdenum to stoichiometric NiAl reduced the as-cast grain size and significantly increased both room- and elevated-temperature strength and ductility.

NACA TN 3834

EFFECT OF AMBIENT-TEMPERATURE VARIATION ON THE MATCHING REQUIREMENTS OF INLET-ENGINE COMBINATIONS AT SUPERSONIC SPEEDS. Eugene Perchonok and Donald P. Hearth. January 1957. 16p. diagrs. (NACA TN 3834)

The changes in ambient temperature ordinarily encountered in flight can markedly influence the performance of matched inlet-engine combinations for turbojet engines operated at constant mechanical speed. If variable geometry is designed into the inlet, the inlet should be sized for the lowest ambient temperature to be encountered regularly. Moreover, the capacity of the variable-geometry feature utilized must be appreciably increased over that for a constant ambient-temperature design. In addition, the capacity of certain matching techniques may be inadequate if both variations in free-stream Mach number and ambient temperature are considered.

NACA TN 3841

DISTRIBUTION OF NORMAL COMPONENT OF INDUCED VELOCITY IN LATERAL PLANE OF A LIFTING ROTOR. Walter Castles, Jr., and Howard L. Durham, Jr., Georgia Institute of Technology. December 1956. 26p. diagrs., tabs. (NACA TN 3841)

Values of the nondimensional normal component of induced velocity in the lateral plane of a uniformly loaded lifting rotor are given in the form of graphs and tables. The necessary auxiliary equations are given so that the graphs or tables of the induced velocity ratios may be used to estimate numerical values of the normal component of induced velocity and the associated flow angle in the lateral plane of any given rotor or set of laterally disposed rotors.

NACA TN 3842

CREEP BEHAVIOR OF STRUCTURAL JOINTS OF AIRCRAFT MATERIALS UNDER CONSTANT LOADS AND TEMPERATURES. Leonard Mordfin and Alvin C. Legate, National Bureau of Standards. January 1957. 53p. diagrs., tabs. (NACA TN 3842)

The results of 55 creep and creep-rupture tests on structural joints are presented. Methods are described by which the time to rupture, the mode of rupture, and the deformation of joints in creep may be predicted. These methods utilize creep data on the materials of the joint in tension, bearing, and shear.

NACA TN 3860

METHOD FOR CALCULATING EFFECTS OF DISSOCIATION ON FLOW VARIABLES IN THE RELAXATION ZONE BEHIND NORMAL SHOCK WAVES. John S. Evans. December 1956. 52p. diagrs., tabs. (NACA TN 3860)

Generalized expressions and charts are presented for the temperature, pressure, density, and flow velocity behind a shock wave that depend on the shock Mach number, the initial state of the gas, and an enthalpy parameter. The variation of this parameter behind the shock is related directly to the variation of the degree of dissociation. Estimated chemical reaction rates are used to illustrate the application of these results for the prediction of the variation of flow properties with distance behind a Mach number 14 shock wave in air at 300° K and 10^{-4} atmospheres.

NACA TN 3861

AERODYNAMIC CHARACTERISTICS OF A CIRCULAR CYLINDER AT MACH NUMBER 6.86 AND ANGLES OF ATTACK UP TO 90°. Jim A. Penland. January 1957. 32p. diagrs., photos. (NACA TN 3861. Supersedes RM L54A14)

Pressure-distribution and force tests of a circular cylinder have been made in the Langley 11-inch hypersonic tunnel at a Mach number of 6.86, a Reynolds number of 129,000, and angles of attack up to 90°. The results are compared with the hypersonic approximation of Grimminger, Williams, and

CURRENT NACA RESEARCH REPORTS

Young and a simple modification of the Newtonian flow theory. An evaluation of the crossflow theory is made through comparison of present results with available crossflow Mach number drag coefficients.

NACA TN 3862

DETERMINATION OF THE STRUCTURAL DAMPING COEFFICIENTS OF SIX FULL-SCALE HELICOPTER ROTOR BLADES OF DIFFERENT MATERIALS AND METHODS OF CONSTRUCTION. Frederick W. Gibson. December 1956. 19p. diagrs., tab. (NACA TN 3862)

Results of an experimental investigation of the structural damping of six full-scale helicopter rotor blades, made to determine the variation of structural damping with materials and methods of construction, are presented. The damping of the blades was determined for the first three flapwise bending modes, first chordwise bending mode, and first torsion mode. The contribution of structural damping to the total damping of the blades is discussed for several aerodynamic conditions in order to point out situations where structural damping is significant.

NACA TN 3863

WIND-TUNNEL INVESTIGATION AT LOW SPEEDS TO DETERMINE THE EFFECT OF ASPECT RATIO AND END PLATES ON A RECTANGULAR WING WITH JET FLAPS DEFLECTED 85°. John G. Lowry and Raymond D. Vogler. December 1956. 21p. diagrs., tab. (NACA TN 3863)

Results are given of an investigation of the effect of aspect ratio and end plates on the aerodynamic characteristics of wings with a jet flap deflected 85° and operating with momentum coefficients from 0 to 17.5. The wings were unswept rectangular NACA 0012 airfoil sections modified for jet flaps. The lift coefficients increased with end plates and aspect ratio, and a design chart for estimating jet-circulation lift for various aspect ratios is included.

NACA TN 3864

THEORETICAL CALCULATION OF THE POWER SPECTRA OF THE ROLLING AND YAWING MOMENTS ON A WING IN RANDOM TURBULENCE. John M. Eggleston and Franklin W. Diederich. December 1956. 56p. diagrs., tabs. (NACA TN 3864)

An analytical solution is derived for the power spectral density of the rolling- and yawing-moment coefficients of a wing subjected to random isotropic atmospheric turbulence. The theory considers the random variations of the turbulence in the spanwise as well as the flight-path direction. Horizontal, vertical, and side gust components are considered. Plots of the power spectra are presented.

NACA TN 3866

FATIGUE TESTS ON NOTCHED AND UNNOTCHED SHEET SPECIMENS OF 2024-T3 AND 7075-T6 ALUMINUM ALLOYS AND OF SAE 4130 STEEL WITH SPECIAL CONSIDERATION OF THE LIFE RANGE FROM 2 TO 10,000 CYCLES. Walter Illg. December 1956. 40p. diagrs., photo., tabs. (NACA TN 3866)

Fatigue tests were performed on notched and unnotched fatigue specimens made of 2024-T3 and 7075-T6 aluminum alloys and of SAE 4130 steel. The notched specimens had theoretical stress-concentration factors of 2.0 and 4.0 and the mean loads were 0 and 20 or 50 ksi. It was found that repeated applications of stresses in the vicinity of the ultimate strength on notched and unnotched specimens produced failures in a much smaller number of cycles than might be inferred from previously published data. Ratios of fatigue strengths of unnotched specimens to those of notched specimens are given.

NACA TN 3872

EXPERIMENTAL DETERMINATION OF THE RANGE OF APPLICABILITY OF THE TRANSONIC AREA RULE FOR WINGS OF TRIANGULAR PLAN FORM. William A. Page. December 1956. 22p. diagrs., photos. (NACA TN 3872)

Further knowledge regarding the range of applicability of the transonic area rule has been gained by the results of an experimental investigation at transonic speeds of the zero-lift drag rise of a family of related wings of triangular plan form in combination with a cylindrical body.

NACA TN 3874

EXPERIMENTAL AND PREDICTED LATERAL-DIRECTIONAL DYNAMIC-RESPONSE CHARACTERISTICS OF A LARGE FLEXIBLE 35° SWEPT-WING AIRPLANE AT AN ALTITUDE OF 35,000 FEET. Stuart C. Brown and Euclid C. Holleman. December 1956. 74p. diagrs., photo., tabs. (NACA TN 3874)

Lateral-directional dynamic-response characteristics of a large flexible 35° swept-wing airplane at an altitude of 35,000 feet are presented. Frequency responses, transfer functions, and stability derivatives are evaluated from transient responses obtained from abrupt aileron or rudder inputs. The measured dynamic responses are compared with predicted responses for the airplane treated as both rigid and flexible.

NACA TN 3875

THE SIMILARITY RULES FOR SECOND-ORDER SUBSONIC AND SUPERSONIC FLOW. Milton D. Van Dyke. January 1957. 20p. diagrs. (NACA TN 3875)

The similarity rules for linearized compressible flow theory (Göthert's rule and its supersonic counterpart) are extended to second order. It is shown that any second-order subsonic flow can be related to "nearly incompressible" flow past the same body, which can be calculated by the Janzen-Rayleigh method.

CURRENT NACA RESEARCH REPORTS

NACA TN 3889

PRESSURE LOSSES OF TITANIA AND MAGNESIUM SLURRIES IN PIPES AND PIPELINE TRANSITIONS. Ruth N. Weltmann and Thomas A. Keller. January 1957. 22p. diagrs., photo., tab. (NACA TN 3889)

Experimental and calculated pressure losses are presented for Newtonian fluids and non-Newtonian slurries for laminar, transitional, and turbulent flow in straight pipelines and pipe transitions such as valves, 90° elbows, contractions, and expansions. Transition loss coefficients, which are independent of the flow rate in the pipeline even in laminar flow, were determined for these transitions. It was found that the transition loss coefficients for Newtonian fluids can be used in the calculations for the design of a pipeline system for the non-Newtonian slurries studied.

NACA TN 3890

ON POSSIBLE SIMILARITY SOLUTIONS FOR THREE-DIMENSIONAL INCOMPRESSIBLE LAMINAR BOUNDARY LAYERS. III - SIMILARITY WITH RESPECT TO STATIONARY POLAR COORDINATES FOR SMALL ANGLE VARIATION. Howard Z. Herzig and Arthur G. Hansen. January 1957. 36p. diagrs., photos., tab. (NACA TN 3890)

Approximate solutions are obtained describing mainstream flows confined to regions of small angle variation over flat surfaces for three-dimensional, laminar, incompressible, thin boundary-layer flows having similarity with respect to stationary polar coordinate systems. The solutions, summarized in a table, include accelerating or decelerating flows and stagnation-point, spiral, or circular flows. An experimental comparison of limiting overturning at the wall showed good agreement for the first 10° turning of circular mainstream flow.

NACA TN 3892

PERFORMANCE OF 110-MILLIMETER-BORE M-1 TOOL STEEL BALL BEARINGS AT HIGH SPEEDS, LOADS, AND TEMPERATURES. William J. Anderson. January 1957. 38p. diagrs., photos., tabs. (NACA TN 3892)

Eleven bearings lubricated with a synthetic of the diester type were run at speeds to 14,000 rpm and bearing temperatures to 678° F. Eight bearings failed in fatigue indicating that the fatigue life of M-1 bearings might be much shorter than the life (based on catalog ratings) of SAE 52100 bearings lubricated with mineral oil. Iron-silicon bronze and silver-plated iron-silicon bronze cages showed negligible wear, but the silver plate showed some tendency to blister and peel. Cast inconel coated with nickel oxide was not a satisfactory cage material at these temperatures and speeds.

NACA TN 3893

THEORY AND DESIGN OF A PNEUMATIC TEMPERATURE PROBE AND EXPERIMENTAL RESULTS OBTAINED IN A HIGH-TEMPERATURE GAS STREAM. Frederick S. Simmons and George E. Glawe. January 1957. 41p. diagrs., photo. (NACA TN 3893)

The basic theory of pneumatic temperature probes and deviations from this basic theory in practical application are presented. Design requirements and operating considerations are discussed. Temperatures between 1600° and 4000° R were measured with an experimental probe in hydrocarbon combustion exhaust gases and compared with those measured by thermocouples and a line-reversal pyrometer. Reasonable agreement among the instruments was obtained.

NACA TN 3895

OBLIQUE-SHOCK RELATIONS AT HYPERSONIC SPEEDS FOR AIR IN CHEMICAL EQUILIBRIUM. W. E. Moeckel. January 1957. 18p. diagrs., tab. (NACA TN 3895)

Oblique-shock relations for air in chemical equilibrium have been calculated for flight velocities up to 25,000 feet per second at altitudes up to 200,000 feet. Results show that those shock parameters which are functions only of Mach number normal to the shock for an ideal gas are strongly influenced by flight altitude (initial conditions), as well as normal Mach number, when dissociation takes place.

NACA TN 3896

SUBSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECT OF FUSELAGE AFTERBODY ON DIRECTIONAL STABILITY OF WING-FUSELAGE COMBINATIONS AT HIGH ANGLES OF ATTACK. Edward C. Polhamus and Kenneth P. Spreemann. December 1956. 25p. diagrs., photo., tab. (NACA TN 3896)

A wind-tunnel study of the directional stability characteristics at high angles of attack of two wing-fuselage combinations has been conducted at subsonic speeds. The wings utilized were a 4-percent-thick unswept wing of aspect ratio 3.0 and a 6-percent-thick 45° sweptback wing of aspect ratio 4. The results indicated very large differences in the directional stability between the two wing-fuselage configurations at high angles of attack. Tests with the fuselage afterbody removed indicated that these effects were associated with wing induced sidewash over the fuselage afterbody.

NACA TN 3897

INCOMPLETE TIME RESPONSE TO A UNIT IMPULSE AND ITS APPLICATION TO LIGHTLY DAMPED LINEAR SYSTEMS. James J. Donegan and Carl R. Huss. December 1956. 17p. diagrs. (NACA TN 3897)

A study is made of the use of the incomplete time response to a unit impulse as a device to analyze lightly damped linear systems. The results indicate that such a system can be adequately described by an incomplete time response to a unit impulse which is computed from the incomplete-output time history (without the addition of an estimated end correction) and the complete-input time history. The incomplete response to a unit impulse may be used with Duhamel's integral to predict the response of the system to an arbitrary input up to at least 90 percent of the cutoff time of the incomplete-output time response.

NACA TN 3898

WIND-TUNNEL INVESTIGATION OF AN EXTERNAL-FLOW JET-AUGMENTED SLOTTED FLAP SUITABLE FOR APPLICATION TO AIRPLANES WITH POD-MOUNTED JET ENGINES. John P. Campbell and Joseph L. Johnson, Jr. December 1956. 47p. diagrs., tab. (NACA TN 3898)

A wind-tunnel investigation has been carried out to determine the characteristics of an external-flow jet-augmented slotted flap which appears suitable for application to airplanes with pod-mounted jet engines. The investigation included tests of an aspect-ratio-6 unswept wing and of a model of a swept-wing jet transport or bomber over a momentum coefficient range up to about 8. The jet transport or bomber model had a 30° sweptback wing with an aspect ratio of 6.62.

NACA TN 3899

EFFECTS OF WING POSITION AND VERTICAL-TAIL CONFIGURATION ON STABILITY AND CONTROL CHARACTERISTICS OF A JET-POWERED DELTA-WING VERTICALLY RISING AIRPLANE MODEL. Powell M. Lovell, Jr., and Lysle P. Parlett. January 1957. 35p. diagrs., photos., tab. (NACA TN 3899)

The results of a flight- and force-test investigation to determine the effects of wing position and vertical-tail configuration on the stability and control characteristics of a jet-powered delta-wing vertically rising airplane model are presented. The model had conventional flap-type controls in addition to jet-reaction controls. The effects of various artificial stabilizing devices were determined.

NACA TN 3901

SHEAR STRENGTH AT 75° F TO 500° F OF FOURTEEN ADHESIVES USED TO BOND A GLASS-FABRIC-REINFORCED PHENOLIC RESIN LAMINATE TO STEEL. John R. Davidson. December 1956. 21p. diagrs., photo., tab. (NACA TN 3901)

Fourteen adhesives used to bond a glass-fabric-reinforced phenolic resin laminate to steel were tested in order to determine their shear strengths at temperatures from 75° F to 500° F. Fabrication methods were varied to evaluate the effect of placing cloth between the faying surfaces to maintain a uniform bond-line thickness. One glass-fabric supported phenolic adhesive was found to have a shear strength of 3,400 psi at 300° F and over 1,000 psi at 500° F. Strength and fabrication data are tabulated for all adhesives tested.

NACA TN 3902

RESULTS OF TWO FREE-FALL EXPERIMENTS ON FLUTTER OF THIN UNSWEPT WINGS IN THE TRANSONIC SPEED RANGE. William T. Lauten, Jr., and Herbert C. Nelson. January 1957. 20p. diagrs., photo., tabs. (NACA TN 3902. Supersedes RM L51C08)

Results of four thin, unswept, flutter airfoils attached to two freely falling bodies are reported. Two airfoils fluttered at a Mach number of 0.85, a third airfoil fluttered at a Mach number of 1.03, and a fourth fluttered at a Mach number of 1.07. Results of calculations of flutter speed using incompressible and compressible air-force coefficients, including a Mach number of 1.0, are presented.

NACA TN 3904

INVESTIGATION OF THE EFFECTIVENESS OF BOUNDARY-LAYER CONTROL BY BLOWING OVER A COMBINATION OF SLIDING AND PLAIN FLAPS IN DEFLECTING A PROPELLER SLIPSTREAM DOWNWARD FOR VERTICAL TAKE-OFF. Kenneth P. Spreemann and Richard E. Kuhn. December 1956. 44p. diagrs., photo. (NACA TN 3904)

An investigation was conducted in order to determine the effectiveness of blowing a jet of air over the flaps of a wing equipped with a 50-percent-chord sliding flap and a 25-percent-chord plain flap in deflecting a propeller slipstream downward for vertical take-off and the results are presented herein. The effects of a leading-edge slat, ground proximity, end plate, and propeller position were also investigated. The tests were conducted in a static-thrust facility at the Langley Aeronautical Laboratory.

NACA TN 3907

SIMILITUDE RELATIONS FOR FREE-MODEL WIND-TUNNEL STUDIES OF STORE-DROPPING PROBLEMS. Carl A. Sandahl and Maxime A. Faget. January 1957. 26p. diagrs., photos., tab. (NACA TN 3907)

Two methods, in which the model and prototype Mach numbers are assumed equal and the Reynolds number effects are assumed negligible, are presented for scaling store models for wind-tunnel store-dropping studies. The light-model method gives exact simulation except that vertical displacements are deficient; this deficiency is reduced as the ejection velocity is increased, or it may be eliminated by accelerating the parent model upward. The heavy-model method gives complete simulation of the store motions except that the short-period oscillation is too poorly damped; this defect is inconsequential during the first phase of a drop. A brief description of the method of conducting store-dropping tests in the preflight jet of the Langley Pilotless Aircraft Research Station at Wallops Island, Va., is given.

NACA TN 3911

A METHOD FOR PREDICTING LIFT INCREMENTS DUE TO FLAP DEFLECTION AT LOW ANGLES OF ATTACK IN INCOMPRESSIBLE FLOW. John G. Lowry and Edward C. Polhamus. January 1957. 29p. diagrs. (NACA TN 3911)

A method is presented for estimating the lift due to flap deflection at low angles of attack in incompressible flow. In this method provision is made for the use of incremental section-lift data for estimating the effectiveness of high-lift flaps. The method is applicable to swept wings of any aspect ratio or taper ratio. The present method differs from other current methods mainly in its ease of application and its more general application. Also included is a simplified method of estimating the lift-curve slope throughout the subsonic speed range.

NACA TN 3915

FLIGHT INVESTIGATION OF A ROLL-STABILIZED MISSILE CONFIGURATION AT VARYING ANGLES OF ATTACK AT MACH NUMBERS BETWEEN 0.8 AND 1.79. Jacob Zarovsky and Robert A. Gardiner. January 1957. 36p. diagrs., photos., tab. (NACA TN 3915. Supersedes RM L50H21)

A missile research model was flown at supersonic speed to determine the quality of automatic roll stabilization at varying angles of attack. Aerodynamic rolling and pitching derivatives were determined from the flight record. It was concluded that the combination of the gyro-actuated automatic pilot with wing-tip ailerons provided adequate roll stabilization under conditions encountered in flight.

NACA TN 3922

ANALYTICAL INVESTIGATION OF THE EFFECT OF WATER INJECTION ON SUPERSONIC TURBOJET-ENGINE - INLET MATCHING AND THRUST AUGMENTATION. Andrew Beke. January 1957. 25p. diagrs. (NACA TN 3922)

Evaporation cooling by water injection in the subsonic diffuser was investigated. Results indicate that fixed-geometry inlets spilling 50 percent of engine airflow without water injection can be matched with water injection without spillage and with 56 percent higher thrusts than for a variable inlet. Liquid impulses with injection were lower than for a bypass inlet but were about equal to a fixed inlet. Maximum liquid consumption at Mach 2.0 was over twice that of the bypass but was only 56 percent greater at the same thrust levels. Diffuser cooling increased top flight speed from Mach 2.0 to 2.6, while cruise altitudes of vehicles without injection could be increased from 55,000 to 67,000 feet.

NACA TN 3941

COMPARISON OF CALCULATED AND EXPERIMENTAL LOAD DISTRIBUTIONS ON THIN WINGS AT HIGH SUBSONIC AND SONIC SPEEDS. John L. Crigler. January 1957. 46p. diagrs., tab. (NACA TN 3941)

A method for calculating the aerodynamic loading on a wing in combination with a body is presented. Calculated results are compared with experimentally measured data for two wing-body configurations throughout a range of Mach number up to 1.0. The magnitude and the distribution of spanwise loading of the calculated data are generally in good agreement with the experimental data.

A COMPARISON OF THE FATIGUE PROPERTIES OF THE HIGH-STRENGTH ALUMINUM-COPPER-ZINC ALLOYS WITH THE ALUMINUM-COPPER DURALUMIN TYPE ALLOYS. R. G. Ward. April 1956. 27p. diagrs., tabs. (RAE Tech.Note Met.244)

Using data from British and American sources for round specimens in reversed bending, an attempt is made to compare the fatigue properties of the complex zinc-bearing aluminum alloys as typified by DTD 363, DTD 683, and 75S, and the simple aluminum-copper alloys such as DTD 150, DTD 364, and 14S. Under all conditions of testing the performance of the high-strength alloys, if judged by the ratio of alternating stress/U.T.S., is inferior to that of the older aluminum-copper alloys, and it is emphasized that designing to static-strength requirements would result in a lower fatigue life for structures of the high-strength alloys.

SOME OBSERVATIONS ON CORROSION AND THE FATIGUE TESTING OF AIRCRAFT IN WATER TANKS. N. J. Wadsworth. August 1956. 10p. diagrs. (RAE Tech.Note Met.246)

The corrosive effects of water upon fatigue life of pressure cabins when tested in water, and corresponding effects in service are reviewed. It is concluded that fatigue life is reduced by mild forms of corrosion in both cases. It is suggested that until more is known auxiliary tests should be made during all tank tests of airplanes, and that all parts of the tank should be painted. It is considered that, while local corrosive effects in the tank may have to be tolerated, measures should be taken to prevent corrosion on an extended scale.

WIND TUNNEL TESTS ON THE EFFECT OF SPAR VARIATIONS ON THE FLUTTER OF A MODEL WING. D. R. Gaukroger. July 1956. 12p. diagrs., photo., tabs. (RAE Tech.Note Structures 203)

Results are given of wind-tunnel flutter tests to determine the effects of variations in spar structural properties in a model wing. A segmented model was built for the investigation, and the tests were made in a low-speed wind tunnel. The design of the model enabled different flexural axis positions to be obtained over the inboard and outboard portions of the wing. The spanwise stiffness distribution of the wing was also variable. Twenty-seven different spar combinations were tested, and in each condition the model was resonance tested and its flutter speed measured. It is concluded that the effect of the spar variations on flutter speed is no greater than would be expected from theoretical considerations.

Royal Aircraft Establishment (Gt. Brit.)
HALF-WAVE MAGNETIC AMPLIFIER BEHAVIOUR. J. Baranowski. May 1956. 38p. diagrs. (RAE Tech.Note EL 119)

Half-wave magnetic amplifier circuits, as proposed by C. W. Lufcy for servomotor control, are examined experimentally with a-c. input control signals. Magnetic cores of Mumetal (80 percent Ni), Permalloy F (65 percent Ni) and H.C.R. alloy (50 percent Ni) are used to establish the importance or otherwise of rectangular B-H properties. Interaction between stages in a cascade is investigated and for rectangular and nonrectangular materials it is shown that the flux reset processes differ and the quiescent triggering angles for magnetic amplifiers based on the two kinds of materials should differ accordingly. For nonrectangular hysteresis loop materials the nature of the interaction between stages results in there being advantages in 120° phase-shift of the supply voltages for cascaded stages. Use of a three-phase supply provided the desired effect without the need for special phase-shifting circuits. The improvement in gain and characteristic shape that is obtained is substantial for Mumetal and the static performance with a three-phase supply surpasses that of a rectangular loop material such as Permalloy F. The dynamic performance with Mumetal cores and a three-phase supply system remains to be examined.

A STUDY OF HYDROGEN EMBRITTLEMENT OF IRON BY INTERNAL-FRICTION AND X-RAY METHODS. R. E. Maringer, L. L. Marsh, and G. K. Manning. June 30, 1956. 76p. diagrs., photos., tab. (Battelle Memorial Inst.)

The effects of hydrogen introduced into high-purity iron and tempered 4340 steel by electrolysis on the internal friction at temperatures from -196° to 420° C were studied. The grain size of some of the iron specimens was coarsened to give essentially single crystals; certain of these single-crystal specimens were further purified by wet-hydrogen treatment before testing. The location and magnitude of the internal friction peaks, both before and after charging, are shown. Results are rationalized in terms of dislocation theory. Diffusion rates of hydrogen, calculated from peaks attributed to hydrogen, are compared with previously reported values. Photomicrographs showing damage resulting from hydrogen charging are included.

NACA RM A51J19

EXPERIMENTAL AND THEORETICAL STUDY OF FACTORS INFLUENCING THE LONGITUDINAL STABILITY OF AN AIR-TO-AIR MISSILE AT A MACH NUMBER OF 1.4. S. Sherman Edwards. January 1952. 51p. diagrs., photo., tabs. (NACA RM A51J19)

Approximate methods of analysis are applied to the estimation of the normal force and pitching moment of the body and the wing-body and tail-body combinations of an air-to-air missile and to the estimation of the same characteristics of the complete configuration. The results of the calculations are compared with experimentally determined normal force and pitching moments for the missile model obtained at a Mach number of 1.4, at a Reynolds number of 1.26 million, based on the mean aerodynamic chord of the wing. The experimental data and the results of the calculations are presented for a range of angle of attack from 0° to 22°, for angles of bank of 0°, 22-1/2°, and 45°.

NACA RM A51L21

A COMPARISON OF THE CHORDWISE PRESSURE DISTRIBUTION AND SPANWISE DISTRIBUTION OF LOADING AT SUBSONIC SPEEDS ON TWO TRIANGULAR WINGS OF ASPECT RATIO 2 HAVING NACA 0005 AND 0008 SECTIONS. Donald W. Smith and Verlin D. Reed. May 1952. 142p. diagrs., photo., tabs. (NACA RM A51L21)

Measurements of the distribution of surface pressures were made on two wing-body combinations employing a triangular wing having an aspect ratio of 2. The first of these combinations had a wing with the NACA 0008-63 section parallel to the airstream while the wing of the second had the NACA 0005-63 section in the stream direction. The measurements were made for Mach numbers from 0.11 to 0.95 at a constant Reynolds number of 3.0 million. Data were also obtained for Reynolds numbers up to 15.0 million at the lower Mach numbers. A summary of data obtained from previously published force tests of these same models is also included for completeness of the presentation of the effect of wing thickness.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A52I23

INSTRUMENTATION AND CALIBRATION OF TECHNIQUE FOR FLIGHT CALIBRATION OF ANGLE-OF-ATTACK SYSTEMS ON AIRCRAFT. Norman M. McFadden, George R. Holden, and Jack W. Ratcliff. December 1952. 30p. diagrs., photos., tabs. (NACA RM A52I23)

The instrumentation and calibration technique used to determine the position error of angle-of-attack detectors mounted on the forward fuselage of a 35° swept-wing fighter airplane are presented. Corrections are applied to the indications of the reference angle-of-attack vanes for vane floating angle, upwash around the boom, and bending of the boom. The position error due to interference effects of wing and fuselage were measured and found to be negligibly small at the location of the most forward vane.

NACA RM A53L15

THE EFFECTS OF HORIZONTAL-TAIL LOCATION AND SIZE ON THE SUBSONIC LONGITUDINAL AERODYNAMIC CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A TRIANGULAR WING OF ASPECT RATIO 3. Bruce E. Tinling and Armando E. Lopez. March 1954. 85p. diagrs., photo., tabs. (NACA RM A53L15)

Wind-tunnel tests were conducted to evaluate the effects of horizontal-tail location and size on the longitudinal aerodynamic characteristics of an airplane model having a thin triangular wing of aspect ratio 3. The model was tested with horizontal tails, which had areas of either 16.7 or 21.9 percent of the wing area, placed -0.10, 0, 0.10, or 0.20 wing semispan above the wing chord plane, and either 1.2 or 1.5 mean aerodynamic chord behind the moment center. The horizontal tails had aspect ratios of 4 and no sweepback of the 50-percent-chord lines. The tests were conducted at a Reynolds number of 2.5 million at Mach numbers from 0.25 to 0.95.

NACA RM A54L07

THE EFFECTS OF TRAILING-EDGE FLAPS ON THE SUBSONIC AERODYNAMIC CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A TRIANGULAR WING OF ASPECT RATIO 3. Bruce E. Tinling and A. V. Karpen. January 1955. 37p. diagrs., photos., tabs. (NACA RM A54L07)

Wind-tunnel tests were conducted to find the effects of single-slotted flaps on the longitudinal stability at low speed, the rolling effectiveness of trailing-edge ailerons and of differential deflection of the horizontal tail when the flaps were deflected 40°, and the effect of small deflections of the flaps on the lift-drag ratio at Mach numbers up to 0.95.

NACA RM A54L22

THE EFFECT OF A 4-PERCENT-HIGH SPOILER ON BUFFETING FORCES ON AN NACA $65_{(06)}$A004 TWO-DIMENSIONAL AIRFOIL AT SUBSONIC MACH NUMBERS. Jack A. Mellenthin. March 1955. 14p. diagrs., photos., tab. (NACA RM A54L22)

An investigation was conducted in the two-dimensional channel of the Ames 16-foot high-speed wind tunnel to determine the effects on buffeting of a solid-strip spoiler on an airfoil model having the NACA $65_{(06)}$A004 section. The spoiler protruded into the airstream a height equal to 0.04 of the airfoil chord and was mounted at the 0.70-chord station. Data are presented over a Mach number range from 0.30 to 0.64 and a Reynolds number range from about 4.0 million to 7.0 million.

NACA RM A55F02

THEORETICAL INVESTIGATION OF THE EFFECTS OF CONFIGURATION CHANGES ON THE CENTER-OF-PRESSURE SHIFT OF A BODY-WING-TAIL COMBINATION DUE TO ANGLE OF ATTACK AND MACH NUMBER AT TRANSONIC AND SUPERSONIC SPEEDS. J. Richard Spahr. September 1955. 43p. diagrs. (NACA RM A55F02)

A theoretical investigation was made to determine the effects of systematic configuration changes on the center-of-pressure shift of an unbanked canard missile configuration having coplanar triangular-wing and -tail surfaces due to angle of attack and Mach number in the transonic and supersonic ranges. The following geometric variables were investigated independently of the others: ratio of wing semispan to tail semispan, ratio of body radius to wing semispan, ratio of tail length to body length, wing aspect ratio, tail aspect ratio, wing taper ratio, tail taper ratio, wing sweep, tail sweep, ratio of tail height to body radius, and wing-tail interdigitation.

NACA RM A55L08

A THEORETICAL STUDY OF THE LIFTING EFFICIENCY AT SUPERSONIC SPEEDS OF WINGS UTILIZING INDIRECT LIFT INDUCED BY VERTICAL SURFACES. Vernon J. Rossow. March 1956. ii, 59p. diagrs. (NACA RM A55L08)

Pressure fields induced by the fuselage or wing end plates which produce indirect lift on the wing are studied by analyzing models of special design. Although specific optimum shapes are not derived, several airfoil systems studied are more efficient than that theoretically possible with planar wings. It is concluded that the lifting efficiency of planar wings could, in certain cases, be increased by employing the fuselage shape and/or vertical surfaces to induce interference or indirect lift.

NACA RM E52A31

SOME EFFECTS OF CHANGING SOLIDITY BY VARYING THE NUMBER OF BLADES ON PERFORMANCE OF AN AXIAL-FLOW COMPRESSOR STAGE. Raymond M. Standahar and George K. Serovy. April 1952. 46p. diagrs., photos., tabs. (NACA RM E52A31)

An investigation was conducted to determine some of the basic problems and effects involved in a change of solidity accomplished by a change in the number of blades in an axial-flow compressor rotor row and in a complete stage. Rotor data for a range of weight flows at each of five equivalent tip speeds from 669 to 962 feet per second indicated that peak pressure ratio for a given speed was higher and was obtained at a lower weight flow as solidity was increased. The peak efficiencies for the three rotor solidities investigated were nearly equal at a given speed and occurred at lower weight flows as solidity was increased. Complete stage data showed that the high-loss region near the hub behind the low-solidity stator blades was reduced by increasing the stator solidity.

NACA RM E52L18a

FORCE AND PRESSURE-RECOVERY CHARACTERISTICS AT SUPERSONIC SPEEDS OF A CONICAL NOSE INLET WITH BYPASSES DISCHARGING OUTWARD FROM THE BODY AXIS. Andrew Beke and J. L. Allen. March 1953. 20p. diagrs., photo., tab. (NACA RM E52L18a)

Aerodynamic and performance characteristics of a conical spike nacelle-type inlet with two bypasses are presented at Mach numbers of 1.6, 1.8, and 2.0 for angles of attack up to 9°. The bypasses were located 6 inlet diameters downstream of the inlet and were designed to discharge the bypass mass flow outward from the body axis. The inlet was designed to attain a mass-flow ratio of unity at a Mach number of 2.0. It is shown that discharging the bypass mass flow outward from the body nearly doubles the critical drag of a similar configuration but with bypass discharge in an axial direction. As a result of this greater drag, the net force on the model in the flight direction is reduced when comparison is made with the axial discharge case. The lift and pitching-moment coefficients are slightly higher that those for a configuration without bypasses. Approximately 25 percent of the maximum inlet mass flow was discharged through the bypasses, and the pressure-recovery and mass-flow characteristics were in qualitative and quantitative agreement with the results of an investigation of a similar configuration with axial discharge.

NACA RM E53L17a

ROTATING STALL INVESTIGATION OF 0.72 HUB-TIP RATIO SINGLE-STAGE COMPRESSOR. Robert W. Graham and Vasily D. Prian. March 1954. 21p. diagrs., photos., tabs. (NACA RM E53L17a)

The rotating stall characteristics of a 0.72 hub-tip ratio, single-stage compressor were investigated. The stage was a 14-inch-diameter replica of the fourth stage of an experimental multistage compressor. No similarity existed between the frequency and propagation rate of the stall patterns observed in the single-stage replica and those observed in the multistage compressor after the fourth stage. A fatigue failure of the rotor blades occurred during the testing which was attributed to a resonance between the stall frequency and the natural bending frequency of the blades.

NACA RM E53L24a

EFFECT OF PROPERTIES OF PRIMARY FLUID ON PERFORMANCE OF CYLINDRICAL SHROUD EJECTORS. Fred D. Kochendorfer. March 1954. 32p. diagrs. (NACA RM E53L24a)

The effects of the properties of the primary fluid on ejector performance are examined both theoretically and experimentally. Experimental effects are determined by comparing the results obtained for a carbon dioxide primary with those obtained from previous tests with air. Comparisons are made for a series of cylindrical shroud ejectors having diameter ratios varying from 1.1 to 1.6, shroud lengths up to 1.0 primary diameter, and weight-flow ratios up to 0.13. At primary pressure ratios for which the shroud is choked, density changes can be compensated by use of a weight-flow parameter equal to the weight-flow ratio multiplied by the square foot of the temperature ratio and divided by the square root of the molecular weight ratio. The effect of specific heat ratio appears to be small, a change from 1.4 to 1.3 decreasing the weight-flow parameter by an amount which averaged about 0.005. A theoretical analysis is also included to show that the effects of heat transfer between the primary and secondary streams can be large.

NACA RM E54L20

EFFECTS OF TURBINE COOLING WITH COMPRESSOR AIR BLEED ON GAS-TURBINE ENGINE PERFORMANCE. Jack B. Esgar and Robert R. Ziemer. March 1955. 45p. diagrs. (NACA RM E54L20)

Performance variations resulting from cooling-air bleed for a wide range of engine operating conditions for turboprop engines and for both afterburning and nonafterburning turbojet engines were analytically investigated. The effects of compressor bleed for turbine cooling are of such small magnitude that the beneficial effects of high-temperature operation are not materially affected.

NACA RM E54L29a

AN EVALUATION OF ELECTROPOLISHED AND NONELECTROPOLISHED BLADES OF ALLOYS REFRACTALOY 26, M-252, AND WASPALOY IN A J33-9 TURBOJET ENGINE. F. J. Clauss, R. A. Signorelli, and J. R. Johnston. June 1955. 27p. diagrs., photos., tabs. (NACA RM E54L29a)

Electropolished and nonelectropolished blades of alloys Refractaloy 26, M-252, and Waspaloy were evaluated in a J33-9 turbojet engine to determine if blade performance is improved by removal of the surface by electropolishing and to compare the blade performance of the alloys with S-816. The results obtained indicated that blade performance was not improved by electropolishing. The blade performance of Waspaloy was about equal to S-816, while that of M-252 and Refractaloy 26 was less.

NACA RM E55H15

A METHOD FOR DETERMINING THE COMPOSITION OF METHANOL - TRIMETHYL BORATE MIXTURES. Samuel Kaye and Frank Sordyl. November 1955. 11p. diagrs., tabs. (NACA RM E55H15)

A study of mixtures of pure methanol and trimethyl borate showed that the composition can be accurately obtained by a simple density determination. The refractive-index determination gives the composition with much less accuracy. The potentiometric titration of boric acid is also discussed.

NACA RM E56I19

PRELIMINARY INVESTIGATION OF GUY ALLOY AS A TURBOJET-ENGINE BUCKET MATERIAL FOR USE AT 1650° F. R. A. Signorelli, J. R. Johnston, and J. W. Weeton. November 1956. 22p. diagrs., photos., tab. (NACA RM E56I19)

As-cast buckets of Guy alloy, a cast nickel-base material, were run in a J33-9 turbojet engine for cycles of 15 minutes at rated speed and 5 minutes at idle speed. Stress rupture, impact, and engine-performance data indicate that Guy alloy may be considered for bucket use at a temperature of 1650° F. Ductility and impact strength of Guy alloy is limited but appears to be adequate for bucket applications.

NACA RM H54G16

A FLIGHT EVALUATION OF THE STABILITY AND CONTROL OF THE X-4 SWEPT-WING SEMITAILLESS AIRPLANE. Melvin Sadoff and A. Scott Crossfield. August 1954. 48p. diagrs., photos., tab. (NACA RM H54G16)

A flight evaluation of the handling qualities of the swept-wing semitailless X-4 airplane was made. Static and dynamic stability and control investigation covered a speed range from stall to Mach numbers of 0.92. Typical swept-wing instability at moderate lifts was encountered. Unsatisfactory and dangerous self-excited dynamic motions occurred at the high-speed end of the range investigated.

NACA RM H54J25a

FLIGHT MEASUREMENTS OF ELEVON HINGE MOMENTS ON THE XF-92A DELTA-WING AIRPLANE. Clinton T. Johnson and Albert E. Kuhl. January 1955. 26p. diagrs., photos., tab. (NACA RM H54J25a)

Elevon hinge-moment measurements were made during flight tests of the Convair XF-92A delta-wing airplane over the Mach number range from 0.70 to 0.95. Hinge moments were measured during longitudinal elevon pulses, aileron rolls, and windup turns. Data are presented giving the variation of C_{h_δ} and C_{h_α} as determined from these tests.

NACA RM H54K03

THE EFFECT OF BLUNT-TRAILING-EDGE ELEVONS ON THE LONGITUDINAL AND LATERAL HANDLING QUALITIES OF THE X-4 SEMITAILLESS AIRPLANE. Edwin J. Saltzman. January 1955. 29p. diagrs., photos., tab. (NACA RM H54K03)

The effects of thickening the trailing edges of the elevons on the static longitudinal stability and control, and lateral control for the X-4, a swept-wing semitailless airplane are presented. The results of this study are compared with similar tests for the X-4 with conventional elevon trailing edges.

NACA RM H54L03

FLIGHT MEASUREMENTS AT TRANSONIC SPEEDS OF THE BUFFETING CHARACTERISTICS OF THE XF-92A DELTA-WING RESEARCH AIRPLANE. Thomas F. Baker and Wallace E. Johnson. April 1955. 32p. diagrs., photos., tab. (NACA RM H54L03)

Measurements were made on the XF-92A delta-wing airplane of buffet-induced fluctuations in normal acceleration at the airplane center of gravity and of fluctuations in wing structural shear load in the Mach number range from 0.6 to 0.96 at altitudes from 25,000 to 38,000 feet. Airplane normal-force coefficients on the order of 0.7 were attained at Mach numbers less than 0.9. Buffet frequencies and the variations with Mach number, lift, and angle of attack of buffet intensity are given.

NACA RM H55D12

FLIGHT MEASUREMENTS OF WING LOADS ON THE CONVAIR XF-92A DELTA-WING AIRPLANE. Albert E. Kuhl and Clinton T. Johnson. May 1955. 37p. diagrs., photos., tab. (NACA RM H55D12)

Aerodynamic loads were obtained from strain-gage measurements during the NACA flight test program of the XF-92A research airplane. Wing-panel loads were measured during longitudinal pulses and windup turns over the Mach number range from 0.43 to 0.95. The wing-panel loads due to elevon deflection and angle of attack were determined for the Mach number range of these tests.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM H55H25

FLIGHT MEASUREMENTS OF THE VERTICAL-TAIL LOADS ON THE CONVAIR XF-92A DELTA-WING AIRPLANE. Clinton T. Johnson. October 1955. 23p. diagrs., photos., tab. (NACA RM H55H25)

Vertical-tail loads as obtained from strain-gage measurements during the NACA flight test program of the Convair XF-92A research airplane were measured during rudder pulses, rudder-fixed oscillations, and gradually increasing sideslips over the Mach number range from 0.50 to 0.87. The vertical-tail loads resulting from rudder deflection and sideslip angle were determined for the Mach number range of these tests.

NACA RM L9L05a

ANALYTICAL INVESTIGATION OF PROPELLER EFFICIENCY AT HIGH-SUBSONIC FLIGHT SPEEDS NEAR MACH NUMBER UNITY. Jean Gilman, Jr., John L. Crigler, and F. Edward McLean. February 13, 1950. 31p. diagrs. (NACA RM L9L05a)

The paper presents results of calculations to determine probable peak efficiency levels of single-rotating propellers operating at high-subsonic flight speeds near sonic velocity. Propeller drag losses are evaluated with airfoil-section data in the transonic range obtained from preliminary results of special propeller tests and with calculated airfoil-section data in the supersonic range. Use is made of conventional vortex theory in evaluating the induced losses.

NACA RM L9L06a

INVESTIGATION OF NACA 4-(0)(03)-045 AND NACA 4-(0)(08)-045 TWO-BLADE PROPELLERS AT FORWARD MACH NUMBERS TO 0.925. James B. Delano and Melvin M. Carmel. January 18, 1950. 22p. diagrs., photo. (NACA RM L9L06a)

The paper presents propeller characteristics for the NACA 4-(0)(03)-045 two-blade propeller for a blade angle of 60° and for the NACA 4-(0)(08)-045 two-blade propeller for blade angles of from 50° to 65° for forward Mach numbers up to 0.925. The results show that important gains in propeller performance are possible at high subsonic forward speeds through reductions in section thickness ratios.

NACA RM L9L20

PLANING CHARACTERISTICS OF SIX SURFACES REPRESENTATIVE OF HYDRO-SKI FORMS. Kenneth L. Wadlin and John R. McGehee. February 10, 1950. 150p. diagrs., photos., tab. (NACA RM L9L20)

Planing characteristics are presented for six planing surfaces. The surfaces varied in plan form and transverse bottom curvature. The plan forms included rectangles, triangles, and their combinations. The bottom curvatures included flat, convex, and concave-convex transverse sections. The ranges of trims and speeds investigated were 4° to 20° and 15 to 35 feet per second. The data are presented in the form of plots of wetted length, load, resistance, trimming moment, and draft against wetted area. Plots of wetted area forward of the observed wetted length at the chine are included.

NACA RM L50L06a

INVESTIGATION OF THE EFFECTS OF LEADING-EDGE CHORD-EXTENSIONS ON THE AERODYNAMIC AND CONTROL CHARACTERISTICS OF TWO SWEPTBACK WINGS AT MACH NUMBERS OF 1.41, 1.62, AND 1.96. Ellery B. May, Jr. January 16, 1951. 25p. diagrs., photo. (NACA RM L50L06a)

A wind-tunnel investigation was made to evaluate the effects of leading-edge chord-extensions on the longitudinal characteristics of swept wings and on control characteristics of flap-type and spoiler-type controls at Mach numbers of 1.41, 1.62, and 1.96. The wings had sharp leading edges and 51.7° leading-edge sweepback with aspect ratios of about 2.4 and taper ratios of about 0.62. The test Reynolds numbers ranged between 1.7×10^6 and 2.0×10^6.

NACA RM L50L14

DYNAMIC LONGITUDINAL STABILITY AND CONTROL OF TANDEM-COUPLED BOMBER-FIGHTER AIRPLANE MODELS WITH RIGID AND PITCH-FREE COUPLINGS. David C. Grana and Donald E. Hewes. January 22, 1951. 12p. diagrs., tabs. (NACA RM L50L14)

The results of flight tests in the Langley free-flight tunnel to determine the dynamic longitudinal stability and control characteristics of tandem-coupled bomber-fighter airplane models are presented. The investigation consisted of flight tests of the bomber alone, of a rigidly coupled combination, and of a freely coupled combination for a range of bomber center-of-gravity locations. Force tests were made with the bomber and fighter models alone and with the rigidly coupled combination.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L50L20

EFFECTS OF SPOILER ON AIRFOIL PRESSURE DISTRIBUTION AND EFFECTS OF SIZE AND LOCATION OF SPOILERS ON THE AERODYNAMIC CHARACTERISTICS OF A TAPERED UNSWEPT WING OF ASPECT RATIO 2.5 AT A MACH NUMBER OF 1.90. D. William Conner and Meade H. Mitchell, Jr. January 24, 1951. 33p. diagrs., photo. (NACA RM L50L20)

Spoilers were investigated on two unswept wings in the Langley 9- by 12-inch supersonic blowdown tunnel. Chordwise and spanwise pressure distributions were measured on an unswept airfoil in the presence of a fuselage but without tip effects at $M = 1.96$ and $R = 1.3 \times 10^6$, both with and without a spoiler projected from either the upper or lower surface of the airfoil. Force and moment data were obtained on a semispan wing of aspect ratio 2.5 and taper ratio of 0.625 at $M = 1.90$ and $R = 2.2 \times 10^6$ where spoiler span and spanwise and chordwise location were varied. The spoiler characteristics were compared with flap results on this wing.

NACA RM L51L05

SOME EFFECTS OF AEROELASTICITY AT MACH NUMBERS FROM 0.7 TO 1.6 ON THE ROLLING EFFECTIVENESS OF THIN FLAT-PLATE DELTA WINGS HAVING 45° SWEPT LEADING EDGES AND FULL-SPAN CONSTANT-CHORD AILERONS. Edward T. Marley and Roland D. English. February 1952. 14p. diagrs., photo. (NACA RM L51L05)

Free-flight rocket-model tests at Mach numbers from 0.7 to 1.6 were made on thin flat delta wings having 45° swept leading edges and constant-chord ailerons in order to determine the effects of aeroelasticity on rolling effectiveness and drag. Within the accuracy of the tests the rolling effectiveness was approximately a linear function of the wing torsional rigidity.

NACA RM L52L01a

THE INFLUENCE OF VORTEX GENERATORS ON THE PERFORMANCE OF A SHORT 1.9:1 STRAIGHT-WALL ANNULAR DIFFUSER WITH A WHIRLING INLET FLOW. Charles C. Wood and James T. Higginbotham. February 1953. 38p. diagrs., photo., tab. (NACA RM L52L01a)

Results are presented of an investigation to determine the effect of vortex generators on the performance of a typical annular diffuser having inflow angles of 0°, 15.2°, and 20.6°. One arrangement having vortex generators on both walls of the diffuser improved the performance substantially when compared with no control and resulted in approximately equal values of static-pressure coefficient for all inlet whirl angles tested.

NACA RM L52L15

CONTROL HINGE-MOMENT AND EFFECTIVENESS CHARACTERISTICS OF A HORN-BALANCED, FLAP-TYPE CONTROL ON A 55° SWEPTBACK TRIANGULAR WING OF ASPECT RATIO 3.5 AT MACH NUMBERS OF 1.41, 1.62, AND 1.96. Lawrence D. Guy. January 1953. 29p. diagrs., photo., tab. (NACA RM L52L15)

A wind-tunnel investigation has been made of two horn-balanced flap-type controls (differing only in trailing-edge thickness) mounted on a 55° sweptback, triangular wing of aspect ratio 3.5 at Mach numbers of 1.41, 1.62, and 1.96 and Reynolds numbers of 2.2×10^6, 2.0×10^6, and 1.8×10^6, respectively. Limited tests were conducted in an experimental nozzle at Mach numbers of 0.72 to 0.82 and Reynolds numbers from 1.9×10^6 to 2.2×10^6, respectively. Control hinge moments as well as aerodynamic characteristics of the complete wing-body combination were obtained throughout a maximum control-deflection range of 0° to 20° and a maximum angle-of-attack range of ±20°. Two different size fences, mounted at the parting line between the wing and tip balance area, were tested on the basic configuration.

NACA RM L52L16

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF LONGITUDINAL WING LOCATION AND VARYING BODY SIZE ON THE INTERFERENCE CHARACTERISTICS OF A 45° SWEPTBACK WING. Donald L. Loving. March 1953. 31p. diagrs., photo., tabs. (NACA RM L52L16)

The effect of wing location and body size on the characteristics of a 45° sweptback wing in the presence of a body is presented for Mach numbers from 0.60 to 1.13 at angles of attack of 0°, 2°, 4°, and 7°. The wing was investigated at two longitudinal locations, one 4 inches ahead of the other on the body. The wing, also, was investigated on two differently sized bodies, one approximately 10 percent larger than the other.

NACA RM L52L19

A TRANSONIC WIND-TUNNEL INVESTIGATION OF AN UNSWEPT-WING-BODY COMBINATION AT ANGLES OF ATTACK UP TO 24°. Bruce B. Estabrooks. February 1953. 23p. diagrs., tab. (NACA RM L52L19)

An investigation was conducted in the Langley 8-foot transonic tunnel of an unswept wing at two longitudinal positions on a body at angles of attack up to 24° at Mach numbers from 0.60 to 1.11. The wing had 0° sweepback of the 0.25-chord line, an aspect ratio of 4, a taper ratio of 0, and 4-percent-thick symmetrical circular-arc airfoil sections parallel to the plane of symmetry. Force and moment characteristics were determined for the unswept-wing-fuselage combinations.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L52L22a

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF A 60° TRIANGULAR WING IN COMBINATION WITH A SYSTEMATIC SERIES OF THREE BODIES. Thomas C. Kelly. April 1953. 22p. diagrs., photo. (NACA RM L52L22a)

Aerodynamic characteristics and the effect of body shape on wing-fuselage interference are presented for a 60° triangular wing at Mach numbers from 0.60 to 1.125 and angles of attack from 0° to 7°. Basic aerodynamic characteristics are also presented for the wing with interference of one configuration through the same Mach number range at angles of attack to 24°. Analysis showed that the principal effects of the various body shapes on the wing-fuselage interference occurred in the transonic range, with the drag characteristics being most significantly affected. Variation of body shape had little interference effect on lift and pitching moment of the wing.

NACA RM L52L31

INVESTIGATION OF SPOILERS AT A MACH NUMBER OF 1.93 TO DETERMINE THE EFFECTS OF HEIGHT AND CHORDWISE LOCATION ON THE SECTION AERODYNAMIC CHARACTERISTICS OF A TWO-DIMENSIONAL WING. James N. Mueller. March 1953. 52p. diagrs., photos. (NACA RM L52L31)

The results of a pressure-distribution investigation of spoilers to determine the effects of height and chordwise location on the section aerodynamic characteristics of a two-dimensional, 6-percent-thick, symmetrical wing are presented for a Mach number of 1.93 and Reynolds number of approximately 1×10^6. The values of section normal force and pitching moment are presented as a function of angle of attack, spoiler height, and spoiler chordwise location. Some effects of spoiler height on spoiler pressure drag are shown for several angles of attack and two chordwise spoiler locations.

NACA RM L53B06

PRELIMINARY MEASUREMENTS OF STATIC LONGITUDINAL STABILITY AND TRIM FOR THE XF-92A DELTA-WING RESEARCH AIRPLANE IN SUBSONIC AND TRANSONIC FLIGHT. Thomas R. Sisk and John M. Mooney. March 1953. 19p. diagrs., photo., tab. (NACA RM L53B06)

Preliminary longitudinal-trim and static longitudinal stability measurements were made on the XF-92A delta-wing research airplane from Mach number of 0.18 to 0.97 at altitudes from 11,000 to 40,000 feet.

NACA RM L53E14

PRELIMINARY FLIGHT MEASUREMENTS OF THE DYNAMIC LONGITUDINAL STABILITY CHARACTERISTICS OF THE CONVAIR XF-92A DELTA-WING AIRPLANE. Euclid C. Holleman, John H. Evans, and William C. Triplett. June 1953. 17p. diagrs., tab. (NACA RM L53E14)

Longitudinal airplane oscillations obtained during U. S. Air Force performance tests of the Convair XF-92A airplane have been analyzed to give limited static stability and damping measurements for a Mach number range of 0.59 to 0.94.

NACA RM L53H17a

PERFORMANCE CHARACTERISTICS OF A 24° STRAIGHT-OUTER-WALL ANNULAR-DIFFUSER-TAILPIPE COMBINATION UTILIZING RECTANGULAR VORTEX GENERATORS FOR FLOW CONTROL. Charles C. Wood and James T. Higginbotham. October 1953. 33p. diagrs., tabs. (NACA RM L53H17a)

Results are presented of an investigation to determine the performance and the influence of vortex generators on the performance of a 24° annular-diffuser—tailpipe combination having fully developed pipe flow at the diffuser inlet. Tests were conducted both for axial flow and for flow whirling at 20.6°, at Mach numbers up to 0.40, and Reynolds numbers up to 1.28×10^6. Measurements were made at the diffuser exit and in the tailpipe $8\frac{11}{16}$ inches downstream of the diffuser exit. The best vortex-generator installation improved the diffuser static-pressure rise and downstream radial distribution without significantly altering the loss coefficient. Considering performance, geometry, and weight, the combination of the 24° diffuser and tailpipe compares very favorably in general with a 15° diffuser previously tested.

NACA RM L53J23

PRELIMINARY DRAG MEASUREMENTS OF THE CONSOLIDATED VULTEE XF-92A DELTA-WING AIRPLANE IN FLIGHT TESTS TO A MACH NUMBER OF 1.01. Donald R. Bellman and Thomas R. Sisk. January 1954. 21p. diagrs., photos., tab. (NACA RM L53J23)

Lift and drag data for the Consolidated Vultee XF-92A delta-wing airplane were obtained for Mach numbers from 0.63 to 0.90. The drag coefficients for a lift coefficient of 0.08 are extended to a Mach number of 1.01.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53L09

THE EFFECTS OF CHANGES IN ASPECT RATIO AND TAIL HEIGHT ON THE LONGITUDINAL STABILITY CHARACTERISTICS AT HIGH SUBSONIC SPEEDS OF A MODEL WITH A WING HAVING 32.6° SWEEPBACK. William J. Alford, Jr. and Thomas B. Pasteur, Jr. February 1954. 61p. diagrs., photos., tab. (NACA RM L53L09)

An investigation was made in the Langley high-speed 7- by 10-foot tunnel to determine the effects of changes in horizontal-tail height on the longitudinal stability characteristics of wing-fuselage combinations having 32.6° sweepback and aspect ratios of 3.0, 3.5, and 4.0. Also investigated were the effects of a leading-edge discontinuity. Lift, drag, and pitching-moment data were obtained at Mach numbers of 0.80, 0.90, and 0.93.

NACA RM L53L11

SUMMARY OF SOME ROCKET-MODEL INVESTIGATIONS OF EFFECTS OF WING ASPECT RATIO AND THICKNESS ON AILERON ROLLING EFFECTIVENESS INCLUDING SOME EFFECTS OF SPANWISE AILERON LOCATION FOR SWEPTBACK WINGS WITH ASPECT RATIO OF 8.0. H. Kurt Strass. February 1954. 26p. diagrs., photos., tab. (NACA RM L53L11)

The rolling effectiveness of 0.2-chord, trailing-edge ailerons on high-aspect-ratio sweptback wings over a Mach number range of 0.6 to 1.6 has been investigated by the Langley Pilotless Aircraft Research Division by utilizing rocket-propelled test vehicles in free flight. Some effects of spanwise aileron location on rolling effectiveness were measured by testing ailerons on the inboard half, the outboard half, and the full length of the exposed wings. The test wings had NACA 65_1A012 airfoil sections, an aspect ratio of 8.0, 45° sweepback of the midchord line, and taper ratios of 0.5 and 1.0. In addition, these data are correlated with the results of previous investigations of various plan forms to show some effects of wing aspect ratio and airfoil section thickness ratio.

NACA RM L53L14a

FREE-FLIGHT MEASUREMENTS OF THE ROLLING EFFECTIVENESS AND DRAG OF TRAILING-EDGE SPOILERS ON A TAPERED SWEPTBACK WING AT MACH NUMBERS BETWEEN 0.6 AND 1.4. Eugene D. Schult and E. M. Fields. February 1954. 14p. diagrs., photos. (NACA RM L53L14a)

A limited free-flight investigation of the rolling effectiveness and drag of 0.02-chord trailing-edge spoilers has been conducted between Mach numbers of 0.6 and 1.4 by use of the rocket-model technique. The test wings were swept back 45° at the quarter chord, had a taper ratio of 0.6, an aspect ratio of 4.0, and an NACA 65A006 profile parallel to the free stream. Solid, sharp-edged, half-span spoilers were tested at both inboard and outboard spanwise locations. The inboard spoiler produced considerably more rolling effectiveness but higher drag than the outboard spoiler. Compared with the same spoiler located at the 0.70-chord position, the trailing-edge spoiler had more rolling effectiveness at subsonic speeds but less rolling effectiveness at supersonic speeds. Less drag was obtained with the trailing-edge spoiler than with the same spoiler located at the 0.70-chord position throughout the speed range tested.

NACA RM L53L18a

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS TO DETERMINE THE ROLLING DERIVATIVES OF TWO WING-FUSELAGE COMBINATIONS HAVING TRIANGULAR WINGS, INCLUDING A SEMIEMPIRICAL METHOD OF ESTIMATING THE ROLLING DERIVATIVES. James W. Wiggins. February 1954. 32p. diagrs. (NACA RM L53L18a)

This paper presents results of an investigation to determine the rolling stability derivatives of two wing-body combinations having triangular wings, including a semiempirical method for estimating the rolling derivatives C_{n_p} (yawing moment due to rolling) and C_{Y_p} (lateral force due to rolling). One wing had a leading-edge sweep angle of 45°, aspect ratio of 4, and an NACA 65A006 airfoil section, and the other wing had a leading-edge sweep angle of 60°, aspect ratio of 2.31, and an NACA 65A003 airfoil section. The angle-of-attack range was from 0° to about 13° and the Mach number range was from 0.50 to 0.95.

NACA RM L53L28a

PRESSURES AND ASSOCIATED AERODYNAMIC AND LOAD CHARACTERISTICS FOR TWO BODIES OF REVOLUTION AT TRANSONIC SPEEDS. Harold L. Robinson. March 1954. 34p. diagrs., tab. (NACA RM L53L28a)

Detailed pressure distributions for two bodies of revolution having the same nose shape, one with a cylindrical afterbody and the other with a curved afterbody, have been determined at transonic speeds. The data indicated that the cylindrical body exhibits more desirable stability characteristics than the curved body and that variation of the aerodynamic characteristics with Mach number was rather small. Comparisons with theory are also presented.

NACA RM L54G21

EFFECTS OF DIFFUSER AND CENTER-BODY LENGTH ON PERFORMANCE OF ANNULAR DIFFUSERS WITH CONSTANT-DIAMETER OUTER WALLS AND WITH VORTEX-GENERATOR FLOW CONTROLS. Charles C. Wood and James T. Higginbotham. September 1954. 39p. diagrs., photo., tab. (NACA RM L54G21)

Data obtained in a program to determine the performance improvements attainable through use of boundary layer controls in annular diffusers applicable to turbojet afterburners are summarized for five diffusers tested with and without vortex-generator controls. The diffusers had a constant-diameter outer body and an area ratio of 1:9 to 1. With axial or

DECLASSIFIED NACA RESEARCH REPORTS

whirling inlet flow, reductions in diffuser length produced appreciable losses in performance. A diffuser with an outer-body length equivalent to that of a 15° diffuser and a center body about half that length produced optimum performance.

NACA RM L54K24a

FLIGHT INVESTIGATION AND ANALYSIS OF THE WING DEFORMATIONS OF A SWEPT-WING BOMBER DURING PUSH-PULL MANEUVERS. Alton P. Mayo and John F. Ward. April 1955. 34p. diagrs., photo., tabs. (NACA RM L54K24a)

The results of deflection measurements made at 12 stations on the wing of a swept-wing jet bomber (Boeing B-47A) during 18 push-pull maneuvers are presented in the form of coefficients expressing the deflections due to the zero-lift loads, the additional-lift loads, the pitching-angular-acceleration loads, and the pitching-angular-velocity loads on the airplane. The procedures used to obtain the coefficients are presented, along with comparisons of the experimental deflections and twists with those obtained from theoretical calculations.

NACA RM L54L03a

A LOW-SPEED INVESTIGATION OF A THIN 60° DELTA WING EQUIPPED WITH A DOUBLE SLOTTED FLAP TO DETERMINE THE CHORDWISE PRESSURE DISTRIBUTION AND THE EFFECT OF VANE SIZE. Delwin R. Croom. March 1955. 42p. diagrs., tabs. (NACA RM L54L03a)

Results and discussion are presented of a wind-tunnel investigation to determine the effect of vane size and the chordwise pressure distribution at one spanwise station on a thin 60° delta wing-fuselage configuration equipped with double slotted flaps. Increasing the vane size resulted in a larger increment of lift at zero angle of attack, greater maximum lift, and also extends the flap-deflection range.

NACA RM L54L23

DEVELOPMENT OF A NEW FLUTTER TESTING TECHNIQUE USING A TOWED DYNAMIC AIRPLANE MODEL EQUIPPED WITH AN AUTOMATIC STABILIZING SYSTEM. EXPERIMENTAL AND CALCULATED DYNAMIC STABILITY CHARACTERISTICS FOR SPEEDS UP TO 200 MPH. William C. Schneider. March 1955. 50p. diagrs., photo., tabs. (NACA RM L54L23)

The results of tests of a model-autopilot-towline combination used in the development of a flutter testing technique are presented. Flights were made at speeds up to 200 mph with both rigid and flexible wings. An analytic study of the dynamic stability of the model was made and an attempt was made to correlate the results with experiment.

NACA RM L56F18a

AN EXPERIMENTAL INVESTIGATION OF STING-SUPPORT EFFECTS ON DRAG AND A COMPARISON WITH JET EFFECTS AT TRANSONIC SPEEDS. Maurice S. Cahn. September 1956. 67p. diagrs., tabs. (NACA RM L56F18a)

Various dummy stings were tested on the rear of a related series of afterbody shapes for Mach numbers from 0.80 to 1.10 and Reynolds numbers based on body length from 15.0×10^6 to 17.4×10^6. A method is presented whereby approximate sting interference corrections can be made to models having afterbody shapes and sting supports similar to those of these tests if the Reynolds numbers are of the same order of magnitude and a turbulent boundary layer exists at the model base. Also presented is an analysis of jet duplication by use of a sting.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1234

ON THE KERNEL FUNCTION OF THE INTEGRAL EQUATION RELATING THE LIFT AND DOWNWASH DISTRIBUTIONS OF OSCILLATING FINITE WINGS IN SUBSONIC FLOW. Charles E. Watkins, Harry L. Runyan and Donald S. Woolston. 1955. ii, 16p. tab. (NACA Rept. 1234. Supersedes TN 3131)

The kernel function of an integral equation relating the downwash to the lift distribution of a finite wing oscillating in subsonic compressible flow is treated. The kernel is reduced to a form which is amenable to calculations and the types of singularities are shown. As a check, it is shown that the kernel for the three-dimensional case reduces exactly to the known kernel for the two-dimensional case. In addition, results for the special cases of Mach number of 0 (incompressible case) and frequency of 0 (steady case) are given.

NACA Rept. 1243

HIGH-RESOLUTION AUTORADIOGRAPHY. George C. Towe, Henry J. Gomberg, and J. W. Freeman. University of Michigan. 1955. iii, 52p. diagrs., photos., tabs. (NACA Rept. 1243. Supersedes TN 3209)

This investigation was made to adapt wet-process autoradiography to metallurgical samples to obtain high resolution of segregated radioactive elements in microstructures. Results are confined to development of the technique, which was perfected to a resolution of less than 10 microns. The radioactive samples included carbon-14 carburized iron and steel, nickel-63 electroplated samples, a powder product containing nickel-63, and tungsten-185 in N-155 alloy.

NACA Rept. 1244

FREE-STREAM BOUNDARIES OF TURBULENT FLOWS. Stanley Corrsin and Alan L. Kistler, Johns Hopkins University. 1955. ii, 32p. diagrs., photos. (NACA Rept. 1244. Supersedes TN 3133)

The instantaneously sharp and irregular front which separates turbulent fluid from contiguous "nonturbulent" fluid at a free-stream boundary is studied. The overall behavior of the front is described statistically in terms of its wrinkle-amplitude growth and its lateral propagation relative to the fluid as functions of downstream coordinate. Theoretical analysis is backed up by experimental results.

NACA Rept. 1245

ANALYSIS AND CALCULATION BY INTEGRAL METHODS OF LAMINAR COMPRESSIBLE BOUNDARY LAYER WITH HEAT TRANSFER AND WITH AND WITHOUT PRESSURE GRADIENT. Morris Morduchow, Polytechnic Institute of Brooklyn. 1955. ii, 19p. diagrs., tabs. (NACA Rept. 1245)

A survey of integral methods in laminar-boundary-layer analysis is given. Simple and fairly accurate methods of calculating the properties (including stability) of the laminar compressible boundary layer in an axial pressure gradient with heat transfer at the wall and of determining the separation point in a compressible flow with an adverse pressure gradient over a surface at a given uniform wall temperature are developed. From the equations derived here, conclusions regarding the effect of pressure gradient, Mach number, and wall temperature on the boundary-layer characteristics are derived and illustrated. In particular the effects on skin-friction, heat-transfer coefficient, separation point in an adverse pressure gradient, and stability of the laminar boundary layer are analyzed.

NACA Rept. 1254

FRICTION, WEAR, AND SURFACE DAMAGE OF METALS AS AFFECTED BY SOLID SURFACE FILMS. Edmond E. Bisson, Robert L. Johnson, Max A. Swikert, and Douglas Godfrey. 1956. iii, 19p. diagrs., photos., tab. (NACA Rept. 1254. Supersedes TN 3444)

A summation is presented of NACA results obtained from friction and wear investigations from 1946 to 1954. The results are consistent with theoretical predictions that solid surface films of low shear strength can serve to reduce both friction and surface damage. Metallic oxides can have very marked effects. Wear studies show that the ability of materials to form surface films is an important factor in wear. Solid lubricants (MoS_2 and graphite) are beneficial under severe operating conditions, including temperatures approaching 1000° F; both materials are, however, subject to oxidation at these temperatures.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1269

THEORETICAL SPAN LOAD DISTRIBUTIONS AND ROLLING MOMENTS FOR SIDESLIPPING WINGS OF ARBITRARY PLAN FORM IN INCOMPRESSIBLE FLOW. M. J. Queijo. 1956. ii, 15p. diagrs. (NACA Rept. 1269. Supersedes TN 3605)

A method is presented for determining the span load distribution and rolling moment due to sideslip for wings of arbitrary plan form in incompressible flow. The method was used to prepare charts from which the rolling moment due to sideslip can be obtained for wings having a large variety of aspect ratio, sweep, and taper ratio. Calculated values of span loads and rolling moments are compared with those of other theories and with experimental results.

NACA Rept. 1284

THEORY OF WING-BODY DRAG AT SUPERSONIC SPEEDS. Robert T. Jones. 1956. ii, 7p. diagrs. (NACA Rept. 1284. Supersedes RM A53H18a)

The relation of Whitcomb's "area rule" to the linear formulas for wave drag at slightly supersonic speeds is discussed. By adopting an approximate relation between the source strength and the geometry of a wing-body combination, the wave-drag theory is expressed in terms involving the areas intercepted by oblique planes or Mach planes. The resulting formulas are checked by comparison with the drag measurements obtained in wind-tunnel experiments and in experiments with falling models in free air. Finally, a theory for determining wing-body shapes of minimum drag at supersonic Mach numbers is discussed and some preliminary experiments are reported.

NACA RM E56K14

THEORETICAL ROCKET PERFORMANCE OF JP-4 FUEL WITH MIXTURES OF LIQUID OZONE AND FLUORINE. Vearl N. Huff and Sanford Gordon. January 1957. 22p. diagrs., tabs. (NACA RM E56K14)

Data were estimated by means of a heat-correction equation using data for JP-4 fuel with mixtures of oxygen and fluorine. The estimated data were checked for several cases by direct calculations. The difference in specific impulse between the estimated and directly calculated values was from 0.2 to 0.8 pound-second per pound. The maximum value of specific impulse was 334.9 pound-seconds per pound for a combustion-chamber pressure of 600 pounds per square inch absolute and an exit pressure of 1 atmosphere.

NACA RM E56K21

MATERIAL COMPATIBILITY WITH GASEOUS FLUORINE. Harold G. Price, Jr., and Howard W. Douglass. January 1957. 5p. tab. (NACA RM E56K21)

Static tests on the compatibility of fluorine with nonmetals at atmospheric temperature eliminated many materials from further consideration for use in fluorine systems. Several materials were found compatible at atmospheric pressure. Only Teflon and ruby (aluminum oxide) were compatible at 1500 pounds per square inch gage.

NACA RM E56L10a

THEORETICAL PERFORMANCE OF LIQUID HYDROGEN AND LIQUID FLUORINE AS A ROCKET PROPELLANT FOR A CHAMBER PRESSURE OF 600 POUNDS PER SQUARE INCH ABSOLUTE. Anthony Fortini and Vearl N. Huff. January 1957. 38p. diagrs., tabs. (NACA RM E56L10a)

Performance is given for both frozen and equilibrium composition during isentropic expansion. Data were calculated for equivalence ratios of 1.2 to 0.15, and pressure ratios of 1 to 1500. A correlation is given which permits the determination of performance for a wide range of chamber pressures. The maximum values of specific impulse for frozen and equilibrium composition with an exit pressure of 1 atmosphere were 380.9 and 392.5, respectively.

NACA TN 3700

ON SUBSONIC FLOW PAST A PARABOLOID OF REVOLUTION. Carl Kaplan. February 1957. 21p. diagrs., tab. (NACA TN 3700)

The Janzen-Rayleigh method is utilized for the calculation of the velocity potential for steady subsonic compressible flow past a paraboloid of revolution. Formulas are obtained for the fluid velocity at the solid boundary and along the axis of symmetry and are compared numerically with corresponding formulas for the two-dimensional parabolic cylinder.

NACA TN 3725

AERODYNAMIC INTERFERENCE OF SLENDER WING-TAIL COMBINATIONS. Alvin H. Sacks. January 1957. 81p. diagrs., photos. (NACA TN 3725)

The variations of total forces and moments with angles of attack and sideslip are calculated for a number of slender plane- and cruciform-wing-tail combinations under the assumption that the vortex sheet is fully rolled up ahead of the tail. Significant nonlinearities are found which are discussed at length. Water-tank photographs of the wake in the presence of the tail are presented.

NACA TN 3806

COMPARISON OF NACA 65-SERIES COMPRESSOR-BLADE PRESSURE DISTRIBUTIONS AND PERFORMANCE IN A ROTOR AND IN CASCADE. Willard R. Westphal and William R. Godwin. March 1957. 53p. diagrs., photos. (NACA TN 3806. Supersedes RM L51H20)

An investigation has been conducted to compare the performance of NACA 65-series compressor blades in two-dimensional cascade with that in an axial flow

CURRENT NACA RESEARCH REPORTS

compressor. Blade pressure distributions were obtained by the use of a mercury-seal pressure-transfer device. The comparison indicated that cascade data accurately predicted the turning angle and blade pressure distribution obtained in the compressor at design conditions.

NACA TN 3825

COMPARISON OF MECHANICAL PROPERTIES OF FLAT SHEETS, MOLDED SHAPES, AND POST-FORMED SHAPES OF COTTON-FABRIC PHENOLIC LAMINATES. F. W. Reinhart, C. L. Good, P. S. Turner, and I. Wolock, National Bureau of Standards. January 1957. 60p. diagrs., photos., tabs. (NACA TN 3825)

Tests were conducted to determine the properties of flat sheets, molded shapes, and postformed shapes of cotton-fabric phenolic laminates. Most of the sheet materials showed directional variations in strength when tested parallel to, perpendicular to, and at 45° to the warp yarn in the face ply of the fabric. Industrial postforming decreased the strength of flat sections whereas laboratory postforming had no effect. The strength of curved sections was decreased and the water absorption increased by postforming. The strength of industrially molded parts was significantly less than that of similar sheet laminates whereas the strength of the flat sections of laboratory molded shapes was equal to or higher than that of similar sheet laminates.

NACA TN 3844

THEORY OF SELF-EXCITED MECHANICAL OSCILLATIONS OF HELICOPTER ROTORS WITH HINGED BLADES. Robert P. Coleman and Arnold M. Feingold. Chapter I: THEORY OF SELF-EXCITED MECHANICAL OSCILLATIONS OF HINGED ROTOR BLADES. Robert P. Coleman. Chapter II: THEORY OF MECHANICAL OSCILLATIONS OF ROTORS WITH TWO HINGED BLADES. Arnold M. Feingold. Chapter III: THEORY OF GROUND VIBRATIONS OF A TWO-BLADE HELICOPTER ROTOR ON ANISOTROPIC FLEXIBLE SUPPORTS (REVISED). Robert P. Coleman and Arnold M. Feingold. Appendix B: THE GENERAL EQUATIONS OF MOTION FOR TWO-BLADE ROTORS. George W. Brooks. February 1957. vii, 131p. diagrs. (NACA TN 3844. Supersedes ARR 3G29; WR L-308; ARR 3I13; WR L-312; TN 1184)

A theoretical analysis for the self-excited mechanical oscillations of hinged rotor blades is described and methods for its application are explained. The theory includes the effects of unequal stiffness of the pylon for deflections in different directions and the effects of damping in the hinges and in the pylon. Both the derivation of the characteristic equation and the methods of application of the theory are given. Charts are presented from which the shaft critical and self-excited instabilities can be predicted for a great variety of cases.

NACA TN 3855

THE EFFECT OF FORWARD-FLIGHT SPEED ON THE PROPULSIVE CHARACTERISTICS OF A PULSE-JET ENGINE MOUNTED ON A HELICOPTER ROTOR. Robert D. Powell, Jr. January 1957. 23p. diagrs., photos. (NACA TN 3855)

The effect of helicopter forward flight on the propulsive characteristics of a blade-tip-mounted pulse-jet engine was determined in the Langley full-scale tunnel for forward speeds up to 101 feet per second. For a representative cruising flight speed of 90 feet per second and an engine velocity of about 370 feet per second, a loss in propulsive thrust of about 5.5 percent and a 4-percent increase in specific fuel consumption were obtained. Whirling (centrifugal acceleration of 178g to 286g) at a rotor forward speed of zero resulted in a 10- to 20-percent reduction in engine thrust from that obtained in the tests with the nonwhirling engine.

NACA TN 3873

TABLES OF CHARACTERISTIC FUNCTIONS FOR SOLVING BOUNDARY-VALUE PROBLEMS OF THE WAVE EQUATION WITH APPLICATION TO SUPERSONIC INTERFERENCE. Jack N. Nielsen. February 1957. 245p. diagrs., tabs. (NACA TN 3873)

Tables are presented containing 69,000 values of a set of characteristic functions of two variables which first arose in problems of supersonic wing-body interference. The functions solve boundary-value problems of the second kind for the wave equation in three dimensions with circular cylindrical boundaries or problems of the unsteady heat-conduction equation in two space dimensions with circular boundaries. The functions themselves have the physical significance of cylindrical pressure waves. The tables have extensive use in problems of aerodynamic interference at supersonic speeds.

NACA TN 3877

ON STOKES' STREAM FUNCTION IN COMPRESSIBLE SMALL-DISTURBANCE THEORY. Milton D. Van Dyke. February 1957. 15p. diagrs. (NACA TN 3877)

Stokes' stream function is studied for subsonic or supersonic flow past axisymmetric bodies of small slope. The first-order equation is found to be nonlinear. It can be linearized if one seeks only the formal order of accuracy of the slender-body approximation. In any case, serious loss of accuracy results from imposing the condition of tangent flow at the body on the mass flux rather than on the velocity. In a second approximation, neglect of the nonlinearity leads to a false solution even in the slender-body expansion.

NACA TN 3881

WIND-TUNNEL TECHNIQUE FOR SIMULTANEOUS SIMULATION OF EXTERNAL FLOW FIELD ABOUT NACELLE INLET AND EXIT AIRSTREAMS AT SUPERSONIC SPEEDS. Gerald W. Englert and Roger W. Luidens. January 1957. 25p. diagrs. (NACA TN 3881)

An investigation was made of several ways of simultaneously simulating an external pressure field generated by an engine exhaust jet and an air inlet. The

CURRENT NACA RESEARCH REPORTS

techniques investigated used high-pressure air piped upstream through a simulated jet to the exhaust nozzle of the engine. It was then discharged through perforations in the pipe or in a downstream direction through a target-type reverser at the end of the pipe. This air combined with the engine-inlet air to form a jet contour. The measured results indicated that the pressure field in the vicinity of the exit station and external to a real jet could be adequately simulated while keeping the inlet at critical or supercritical mass flow.

NACA TN 3894

A STUDY OF THE IMPACT BEHAVIOR OF HIGH-TEMPERATURE MATERIALS. H. B. Probst and Howard T. McHenry. March 1957. 23p. diagrs., photos., tabs. (NACA TN 3894)

The impact behavior of titanium carbide base cermets and high-temperature alloys was investigated from room temperature to 1750° F. The effects of amount of binder, binder composition, microstructure, temperature, and stress concentration on the impact strength of cermets are discussed. The NACA drop test was used in order to eliminate "toss energy," and the test variables which affect impact energies measured by the drop test are discussed.

NACA TN 3905

DIFFERENTIAL EQUATIONS OF MOTION FOR COMBINED FLAPWISE BENDING, CHORDWISE BENDING, AND TORSION OF TWISTED NONUNIFORM ROTOR BLADES. John C. Houbolt and George W. Brooks. February 1957. 47p. diagrs. (NACA TN 3905)

The differential equations of motion for the lateral and torsional deformations of twisted rotating beams are developed for application to helicopter rotor and propeller blades. No assumption is made regarding the coincidence of the neutral, elastic, and mass axes, and the generality is such that previous theories involving various simplifications are contained as subcases to the theory developed and presented in this paper. Special attention is given to coupling terms not found in previous theories, and methods of solution of the equations of motion are indicated by selected examples.

NACA TN 3906

FREE-JET TESTS OF A 1.1-INCH-DIAMETER SUPERSONIC RAM-JET ENGINE. Joseph H. Judd and Otto F. Trout, Jr. February 1957. 24p. diagrs., photos., tabs. (NACA TN 3906. Supersedes RM L51L18)

Results are presented of free-jet tests of a 1.1-inch-diameter hydrogen-burning ram-jet engine over a Mach number range from 1.42 to 2.28 and a Reynolds number range from 6.01×10^6 to 15.78×10^6. Tests demonstrated the reliability and wide operating range of the engine and showed its suitability for installation on wind-tunnel models of airplane and missile configurations. A comparison of engine operation with combustion-chamber lengths of 3.33 and 1.51 engine diameters was made at a Mach number of 2.06. A maximum test thrust coefficient of 0.905 was obtained at fuel-air ratio of 0.034 and a Mach number of 2.06 for the engine with the 3.33-diameter combustion chamber.

NACA TN 3909

VERTICAL FORCE-DEFLECTION CHARACTERISTICS OF A PAIR OF 56-INCH-DIAMETER AIRCRAFT TIRES FROM STATIC AND DROP TESTS WITH AND WITHOUT PREROTATION. Robert F. Smiley and Walter B. Horne. February 1957. 41p. diagrs., photo., tabs. (NACA TN 3909)

The vertical force-deflection characteristics were experimentally determined for a pair of 56-inch-diameter tires under static and drop-test conditions with and without prerotation. For increasing force, the tires were found to be least stiff for static tests, almost the same as for the static case for prerotation drop tests as long as the tires remain rotating, and appreciably stiffer for drop tests without prerotation.

NACA TN 3913

SUMMARY OF 65-SERIES COMPRESSOR-BLADE LOW-SPEED CASCADE DATA BY USE OF THE CARPET-PLOTTING TECHNIQUE. A. Richard Felix. February 1957. 18p. diagrs. (NACA TN 3913. Supersedes RM L54H18a)

The carpet-plotting technique is presented in this paper as a more useful and concise method of summarizing cascade data on the NACA 65-series compressor blades given in NACA Technical Note 3916. Carpet plots included permit the selection of the blade camber and the design angle of attack required to fulfill a design vector diagram. Other carpet plots provide means for the prediction of off-design turning angles. Also presented are carpet plots of an isentropic pressure-rise coefficient as a function of inlet-air angle, turning angle, and entering Mach number.

NACA TN 3914

SOME EXPERIMENTAL STUDIES OF PANEL FLUTTER AT MACH NUMBER 1.3. Maurice A. Sylvester and John E. Baker. February 1957. 25p. diagrs., photos., tab. (NACA TN 3914. Supersedes RM L52I16)

Experimental studies of panel flutter using thin metal plates were conducted at a Mach number of 1.3 to verify its existence and to study the effects of some structural parameters on the flutter characteristics. The effects of tensile forces and buckling were studied on panels clamped front and rear, in addition to initially buckled panels clamped on all four edges. Panel flutter was obtained under controlled laboratory conditions and it was found that tensile forces, shortening the panels, and increasing the bending stiffness were effective means for eliminating flutter. Buckled panels were more susceptible to flutter than unbuckled panels. No apparent systematic trends in the flutter modes or frequencies could be observed.

CURRENT NACA RESEARCH REPORTS

NACA TN 3916

SYSTEMATIC TWO-DIMENSIONAL CASCADE TESTS OF NACA 65-SERIES COMPRESSOR BLADES AT LOW SPEEDS. L. Joseph Herrig, James C. Emery, and John R. Erwin. February 1957. 223p. diagrs., photo., tabs. (NACA TN 3916. Supersedes RM L51G31)

A two-dimensional low-speed porous-wall cascade tunnel investigation has been conducted to establish the performance of the NACA 65-series compressor blade sections over the useful range of inlet angle, solidity, and section camber. Design points for optimum high-speed operation are presented. The loading limitation is determined for some conditions. Trends of section operating range with increasing section camber are determined for the four inlet angles tested.

NACA TN 3917

EFFECT OF PROPELLER LOCATION AND FLAP DEFLECTION ON THE AERODYNAMIC CHARACTERISTICS OF A WING-PROPELLER COMBINATION FOR ANGLES OF ATTACK FROM 0° TO 80°. William A. Newsom, Jr. January 1957. 45p. diagrs. (NACA TN 3917)

The investigation was conducted with a model having four propellers, the slipstream from which covered practically the entire span of the wing. The wing had a 30-percent-chord slotted flap and an 8.5-percent-chord slat. The tests covered two longitudinal and two vertical positions of the propeller relative to the wing, and a range of flap deflections, with slat off and slat on. For one propeller position the power input to the model was measured and tuft studies of the flow on the wing were made. The results indicate that with proper propeller position and programming of flap deflection, it is possible to design a configuration for a vertical-take-off-and-landing airplane in which essentially no change in trim is required throughout the transition from hovering to normal unstalled forward flight.

NACA TN 3918

WIND-TUNNEL INVESTIGATION OF EFFECT OF PROPELLER SLIPSTREAMS ON AERODYNAMIC CHARACTERISTICS OF A WING EQUIPPED WITH A 50-PERCENT-CHORD SLIDING FLAP AND A 30-PERCENT-CHORD SLOTTED FLAP. Richard E. Kuhn and William C. Hayes, Jr. February 1957. 72p. diagrs., photo., tab. (NACA TN 3918)

Results are presented of an investigation at low speed of the effect of propeller slipstreams on the aerodynamic characteristics of a wing equipped with a 50-percent-chord sliding flap in combination with a 30-percent-chord slotted flap. Tests covered a thrust-coefficient range representing free-stream velocities from zero to the normal range of cruising speeds and included the effects of flap deflection, stabilizer incidence, and leading-edge-slat settings. Large tunnel-wall effects were experienced for which there is no known correction method; however, because of the current interest in and general scarcity of data applicable to aircraft designed for vertical take-off and landing (VTOL) and for short take-off and landing (STOL), the results are presented without correction for these tunnel-wall effects.

NACA TN 3919

INVESTIGATION OF EFFECTIVENESS OF A WING EQUIPPED WITH A 50-PERCENT-CHORD SLIDING FLAP, A 30-PERCENT-CHORD SLOTTED FLAP, AND A 30-PERCENT-CHORD SLAT IN DEFLECTING PROPELLER SLIPSTREAMS DOWNWARD FOR VERTICAL TAKE-OFF. Richard E. Kuhn. January 1957. 39p. diagrs., photo., tab. (NACA TN 3919)

Results are presented of an investigation of the effectiveness of a wing equipped with a 50-percent-chord sliding flap and a 30-percent-chord slotted flap in deflecting a propeller slipstream downward for vertical take-off. Tests were conducted at zero forward speed in a large room and included the effects of flap deflection, proximity to the ground, a leading-edge slat, and end plates. A turning angle of about 70° and a resultant force of about 100 percent of the thrust were achieved near the ground. Out of the ground-effect region, the turning angle was also about 70° but the resultant force was reduced to about 86 percent of the thrust.

NACA TN 3921

APPROXIMATE SOLUTION FOR STREAMLINES ABOUT A LIFTING ROTOR HAVING UNIFORM LOADING AND OPERATING IN HOVERING OR LOW-SPEED VERTICAL-ASCENT FLIGHT CONDITIONS. Walter Castles, Jr., Georgia Institute of Technology. February 1957. 41p. diagrs., tabs. (NACA TN 3921)

A realistic approximation for low-speed flow patterns is obtained by adding the stream functions for the displacement velocity of a disk and a ring source coincident with the rim of the rotor to the stream functions for the uniform vortex cylinder and the free-stream velocity. Equations are derived for the relative strengths of the stream functions that are necessary to satisfy certain selected physical conditions. Tables of values of the composite stream function are given for hovering and three rates of vertical ascent which cover the helicopter flight range. A method is outlined for using the tabulated values of the stream functions to compute the induced velocity components at any selected locations.

NACA TN 3923

EFFECT OF CHORD SIZE ON WEIGHT AND COOLING CHARACTERISTICS OF AIR-COOLED TURBINE BLADES. Jack B. Esgar, Eugene F. Schum, and Arthur N. Curren. January 1957. 37p. diagrs., tabs. (NACA TN 3923)

This analysis shows that turbine blade weight is affected to a much smaller degree by the size of the blade chord for air-cooled blades than for solid uncooled blades. The heat-transfer analysis shows that considerable savings in coolant flow are possible by using a smaller number of large-chord blades rather than a larger number of small-chord blades (constant blade solidity). In addition to the high coolant flows, the small-chord blades are often unable to pass the required flow at the pressure levels encountered in engine operation.

CURRENT NACA RESEARCH REPORTS

NACA TN 3926

EXPERIMENTAL COMPARISON OF SPEED - FUEL-FLOW AND SPEED-AREA CONTROLS ON A TURBO-JET ENGINE FOR SMALL STEP DISTURBANCES. L. M. Wenzel, C. E. Hart, and R. T. Craig. March 1957. 56p. diagrs. (NACA TN 3926)

Optimum proportional-plus-integral control settings for speed - fuel-flow control, determined by minimization of integral criteria, correlated well with analytically predicted optimum settings. Engine response data are given for a range of control settings around the optimum. An inherent nonlinearity in the speed-area loop necessitated the use of nonlinear controls. Response data for two such nonlinear control schemes are presented.

NACA TN 3927

PRELIMINARY INVESTIGATION OF THE EFFECT OF SURFACE TREATMENT ON THE STRENGTH OF A TITANIUM CARBIDE - 30 PERCENT NICKEL BASE CERMET. Leonard Robins and Edward M. Grala. February 1957. 16p. diagrs., photos., tabs. (NACA TN 3927)

Specimens of a nickel-bonded titanium carbide cermet were given the following surface treatments: (1) grinding, (2) lapping, (3) blast cleaning, (4) acid roughening, (5) oxidizing, and (6) oxidizing and refinishing. Room-temperature modulus-of-rupture and impact strength varied with the different surface treatments. Considerable strength losses resulted from the following treatments: (1) oxidation at 1600° F for 100 hours, (2) acid roughening, and (3) severe grinding with 60-grit silicon carbide abrasive. The strength loss after oxidation was partially recovered by grit blasting or diamond grinding.

NACA TN 3928

BOUNDARY-LAYER TRANSITION AT MACH 3.12 AS AFFECTED BY COOLING AND NOSE BLUNTING. N. S. Diaconis, John R. Jack, and Richard J. Wisniewski. January 1957. 17p. diagrs., photos. (NACA TN 3928)

Transition studies were made on a blunted cone-cylinder and parabolic-nosed cylinder at Reynolds numbers per foot up to 8×10^6. At all temperature levels, blunting the cone-cylinder model yielded increases in transition Reynolds number over that obtained on the sharp model. However, no such increase was obtained by blunting the parabolic model. On both models, moderate cooling resulted in an increase in the transition Reynolds number; extreme cooling, on the other hand, decreased the transition Reynolds number.

NACA TN 3929

A GENERAL SYSTEM FOR CALCULATING BURNING RATES OF PARTICLES AND DROPS AND COMPARISON OF CALCULATED RATES FOR CARBON, BORON, MAGNESIUM, AND ISOOCTANE. Kenneth P. Coffin and Richard S. Brokaw. February 1957. 56p. diagrs., tabs. (NACA TN 3929)

A system with general equations for computing burning rates of small particles has been devised; the effects of diffusion, heat conduction, and dissociation are included. The equations have been applied directly to carbon and boron and reduced to simpler forms used previously for isooctane and magnesium. The simpler computations appear to give sufficient accuracy for many purposes. For the combustion of boron particles, three graphs permit rapid determination of burning rate for a wide range of ambient temperature and ambient partial pressure of oxygen.

NACA TN 3930

STRESS-LIFE RELATION OF THE ROLLING-CONTACT FATIGUE SPIN RIG. Robert H. Butler and Thomas L. Carter. March 1957. 23p. diagrs., photos., tabs. (NACA TN 3930)

The rolling-contact fatigue spin rig was used to test groups of SAE 52100 9/16-inch-diameter balls lubricated with a mineral oil at 600,000-, 675,000-, and 750,000-psi maximum Hertz stress. Cylinders of AISI M-1 vacuum and commercial melts and MV-1 (AISI M-50) were used as race specimens. Stress-life exponents produced agree closely with values accepted in industry. The type of failure obtained in the spin rig was similar to the subsurface fatigue spalls found in bearings.

NACA TN 3931

A STUDY OF THE "TOSS FACTOR" IN THE IMPACT TESTING OF CERMETS BY THE IZOD PENDULUM TEST. H. B. Probst and Howard T. McHenry. February 1957. 13p. diagrs., photo., tab. (NACA TN 3931)

The test method presented shows that the "toss energy" contributed by the apparatus for brittle materials is negligible. The total toss energy is considered to consist of two components, (a) recovered stored elastic energy and (b) kinetic energy contributed directly by the apparatus. The results were verified by high-speed motion pictures of the test in operation. From these photographs, velocities of tossed specimens were obtained and toss energy computed. In addition, impact energies of some titanium carbide base cermets and high-temperature alloys, as measured by the low-capacity Izod pendulum test, compare well with impact energies measured by the NACA drop test.

NACA TN 3933

EFFECT OF FIBER ORIENTATION ON BALL FAILURES UNDER ROLLING-CONTACT CONDITIONS. Robert H. Butler, H. Robert Bear, and Thomas L. Carter. February 1957. 35p. diagrs., photos., tabs. (NACA TN 3933)

The rolling-contact fatigue spin rig was used to test balls of a bearing steel at maximum Hertz stresses of 600,000 to 750,000 psi. The effect of fiber orientation was observed with the ball track restricted to passing directly over the poles, coincident with the equator, or randomly around the ball. The polar areas were found to be weaker in fatigue than the nonpolar areas. This resulted in a much greater portion of the failures occurring in the polar areas than would be expected from a homogeneous material. The early failures are discussed.

CURRENT NACA RESEARCH REPORTS

NACA TN 3938

SIDEWASH IN THE VICINITY OF LIFTING SWEPT WINGS AT SUPERSONIC SPEEDS. Percy J. Bobbitt and Peter J. Maxie, Jr. February 1957. 49p. diagrs. (NACA TN 3938)

Equations and charts have been presented for the conical part of the sidewash above and below swept wings at small angles of attack. This flow-field component is necessary in making calculations of the wing-induced forces and moments on stores, missiles, and pylons. All supersonic Mach numbers and wing leading-edge sweep angles have been considered.

NACA TN 3940

IMPACT-LOADS INVESTIGATION OF CHINE-IMMERSED MODELS HAVING CONCAVE-CONVEX TRANSVERSE SHAPE AND STRAIGHT OR CURVED KEEL LINES. Philip M. Edge, Jr. February 1957. 66p. diagrs., photos., tabs. (NACA TN 3940)

Hydrodynamic-loads data obtained at the Langley impact basin from impacts of a concave-convex transversely curved bottom mounted on narrow-beam models having straight keel, curved bow, and curved stern are presented. Impacts were made at fixed trim angles over a range of landing conditions, including a few rough-water landings. The data are analyzed to show the effects of transverse curvature, longitudinal curvature, and rough water on maximum impact loads for narrow-beam models tested.

NACA TN 3942

INVESTIGATION OF VARIATION IN BASE PRESSURE OVER THE REYNOLDS NUMBER RANGE IN WHICH WAKE TRANSITION OCCURS FOR NONLIFTING BODIES OF REVOLUTION AT MACH NUMBERS FROM 1.62 TO 2.62. Vernon Van Hise. January 1957. 41p. diagrs., photo. (NACA TN 3942)

Results are presented of the effects of Mach number and Reynolds number upon the base pressure of nonlifting ogival bodies of revolution over the Reynolds number range in which wake transition occurs. The Mach number varied from 1.62 to 2.62 and the overall Reynolds number range was approximately from 20,000 to 10,000,000.

NACA TN 3945

METHODS FOR OBTAINING DESIRED HELICOPTER STABILITY CHARACTERISTICS AND PROCEDURES FOR STABILITY PREDICTIONS. F. B. Gustafson and Robert J. Tapscott. February 1957. 28p. diagrs., tabs. (NACA TN 3945. Supersedes RM L54F30; RM L54G05)

Part I summarizes the methods available to the helicopter designer for obtaining desired stability characteristics by modifications to the airframe design. The discussion is based on modifications made during establishment of flying-qualities criteria and includes sample results of theoretical studies of additional methods. In part II some of the methods of predicting rotor stability derivatives have been reviewed and the methods by which the derivatives are employed to estimate stability characteristics are summarized.

NACA TN 3946

DITCHING INVESTIGATIONS OF DYNAMIC MODELS AND EFFECTS OF DESIGN PARAMETERS ON DITCHING CHARACTERISTICS. Lloyd J. Fisher and Edward L. Hoffman. February 1957. 58p. tabs. (NACA TN 3946)

Data from ditching investigations conducted at the Langley Aeronautical Laboratory with dynamic scale models of various airplanes are presented in the form of tables. The effects of design parameters on the ditching characteristics of airplanes, based on scale-model investigations and on reports of full-scale ditchings, are discussed. Various ditching aids are also discussed as a means of improving ditching behavior.

NACA TN 3947

INSTRUMENT FLIGHT TRIALS WITH A HELICOPTER STABILIZED IN ATTITUDE ABOUT EACH AXIS INDIVIDUALLY. Seymour Salmirs and Robert J. Tapscott. January 1957. 17p. diagrs., photo. (NACA TN 3947)

Pilots' opinions and a simplified statistical analysis of the data were used to evaluate the results of helicopter flight investigations of single-axis attitude stabilization during low-speed instrument approaches. During calm-air flight, heading stabilization provided the most favorable results, with pitch stabilization and roll stabilization following in that order. Under variable-wind conditions, pitch stabilization provided the most significant contribution.

NACA TN 3948

PRELIMINARY DATA AT A MACH NUMBER OF 2.40 OF THE CHARACTERISTICS OF FLAP-TYPE CONTROLS EQUIPPED WITH PLAIN OVERHANG BALANCES. James N. Mueller and K. R. Czarnecki. March 1957. 43p. diagrs., photos. (NACA TN 3948. Supersedes RM L52F10)

The preliminary results of an investigation to determine the aerodynamic characteristics of plain overhang balances on flap-type controls are presented for a Mach number of 2.40 and a Reynolds number of 0.78×10^6. The values of section hinge moment, pitching moment, normal force, and chord force as a function of flap deflection and angle of attack for a basic wing equipped with flaps of 38-, 60-, and 82-percent balance are included. Some effects of gap size are shown for the flap of least balance.

NACA TN 3972

EFFECT OF FREQUENCY AND TEMPERATURE ON FATIGUE OF METALS. S. R. Valluri, California Institute of Technology. February 1957. 15p. diagrs. (NACA TN 3972)

Phenomenological considerations applied to a standard-linear-solid physical model indicated that for particular temperatures there are corresponding frequencies of fatigue stressing above which the fatigue behavior changes. It is suggested that at room temperature the critical frequency is above that usually encountered in engineering practice.

Royal Aircraft Establishment (Gt. Brit.)
THE FLIGHT SIMULATOR IN AIRCRAFT CONTROL RESEARCH AND DESIGN. W. J. G. Pinsker. August 1956. 32p. diagrs., photos. RAE Tech. Note Aero 2467. (Request N-46303*)

The possibilities of simulating manually controlled flight are discussed and the principal types of flight simulators are described. Particular attention is given to the importance of realistic visual and physical flight impressions. It is shown that useful conclusions on the handling characteristics of an aircraft can be drawn from experiments on relatively simple simulators. This is illustrated by results obtained on the RAE aiming flight simulator. It is suggested in conclusion that a flight simulator can be a very powerful tool for the design and optimization of aircraft control systems, if sufficiently realistic sensations of flight are simulated. Flight tests will, however, be always necessary as the final check and for the exploration of aerodynamic phenomena, which the simulator cannot predict but only accept as data.

TEMPERATURE AND DIFFUSION NEAR SLIP BANDS DURING FATIGUE. N. J. Wadsworth. August 1956. 21p. RAE Tech. Note Met. 251. (Request N-46955*)

The average and instantaneous temperatures which can occur in slipbands during fatigue tests are discussed. It is shown that the mean temperature of a slipband is not appreciably above that of the surrounding material. The local temperature generated by moving dislocations cannot be sufficient to cause an appreciable increase in local diffusion rate. Increase in diffusion rate can, however, be produced by increases in the concentration of dislocations, vacancies, and interstitials at slipbands. The first two might allow diffusion to occur at about half the temperature normally needed while the third might be effective at even lower temperatures. In addition local atomic rearrangements can occur at all temperatures when dislocations, vacancies, or interstitials are annihilated.

THE FOULING OF TURBINE BLADES BY FUEL ASH. PART IV. PRESSURE TESTS WITH CAMBERED BLADES. J. J. Macfarlane and F. S. E. Whitcher. July 1956. 22p. diagrs., tabs. NGTE R. 193. (Request N-46964*)

This report describes a short series of rig tests to investigate ash deposition and corrosion on a cascade of cambered blades at pressures up to 4 atmospheres absolute. Severe choking of the cascade by low temperature deposits is demonstrated, and limited conclusions are drawn concerning the relationship between weight of deposit and cascade pressure drop. Tests at 700° C using Nimonic 80A blades have confirmed the existence of a maximum rate of corrosion at intermediate rates of deposition of vanadium pentoxide. Two special tests were carried out, using a Kuwait fuel oil of low vanadium content, and suggestions are made concerning the combustion problem raised by these results.

THE EFFECTS OF CONVEX SURFACE CURVATURE ON BOUNDARY LAYER SEPARATION IN SUPERSONIC FLOW. G. E. Gadd. 1956. 16p. diagrs., photos. ARC CP 289. (Request N-48071*)

The effects of convex surface curvature on boundary-layer separation in supersonic flow are investigated experimentally and theoretically. The radius of curvature used in the experiments was about three times the distance from the leading edge of the surface on which the boundary layer was formed to the separation point. In accordance with theory, the surface curvature greatly reduced the separation pressure coefficient for laminar layers, but for turbulent layers (for which no theory of the effects of curvature has yet been developed) there was little effect.

THE ηq METER, A RAPID INSTRUMENTAL METHOD OF COMBUSTION GAS ANALYSIS. F. H. Holderness. November 1956. 52p. diagrs., photos. NGTE R. 194. (Request N-48146*)

An account is given of the operating principles of an apparatus for rapid instrumental gas analytical measurements on combustion gases. An analysis can be completed with the apparatus in 6 to 10 minutes, using a stream of sample taken directly from a combustion chamber. The measurements made are of net carbon dioxide concentration, carbon monoxide, hydrogen, and total carbon dioxide. The last quantity is estimated after all carbon compounds in the sample have been fully oxidized to carbon dioxide in a furnace system. The direct indicating instruments which are incorporated into the meter are two infrared gas analyzers, for carbon dioxide and carbon monoxide measurements, and a sonic gas analyzer for hydrogen measurement. These instruments are described in a section of the report which gives complete constructional details of the meter. The measurements made can be used to derive values of combustion efficiency and fuel/air mixture strength. The calculations involved are included in an appendix. The meter is capable of handling gases from zones where combustion efficiency is in the range 0 to 100 percent and the mixture strength is in the range 0.0125 to 0.125.

BUBBLE-POINTS, FLAMMABILITY LIMITS AND FLASH POINTS OF PETROLEUM PRODUCTS. B. P. Mullins. November 1956. 34p. diagrs., tabs. NGTE R. 200. (Request N-48149*)

Relationships between the bubble points, flammability limits, and flash points of a fuel have been demonstrated numerically for four hydrocarbon fuels ranging from aviation spirit to gas oil. The mean molecular weights of the fuel vapors at the bubble points

BRITISH REPORTS

have been computed and several nomographic methods of presenting corrected bubble-point data are outlined with examples. Weak and rich flammability limits in air of the four fuels were calculated over a range of static pressures. The weak limit curve represents the conditions of the closed flash point test and so by differentiation of this curve a flash point pressure correction factor was obtained for each fuel. Excellent agreement between theoretical and measured values was found in all cases and a simple general rule for estimating flash points is given.

COMPARISON OF THE RESISTANCE TO SHOCK OF LUBRICATING FILMS. (Comparaison de la résistance au choc des films lubrifiants). F. Charron. January 1957. 19p. diagrs., photos., tabs. Translation of Ministere de l'Air Publications Scientifiques et Techniques No. 298, 1955. (Request N-38324*)

The purpose of this paper is to compare the protective properties of lubricating films with regard to continuous or suddenly applied forces. First, a test apparatus is described which has been especially constructed to take care of this double program. The result of steady-state tests shows that the viscosity under atmospheric pressure is a predominant factor whereas the coefficient of the increase of viscosity with pressure appears to be without interest, contrary to expectations. Tests under shock-loading conditions confirm these conclusions. In order to classify lubricants, we form the ratio of breaking-load of the film to the viscosity. This ratio is not constant; it is seen to be higher for certain oils which are particularly suitable for resisting large forces, due to properties little known or even unknown.

OBSERVATIONS REGARDING A CRITERION OF LAMINAR SEPARATION IN THE THREE-DIMENSIONAL BOUNDARY LAYER. (Observations sur un Critere de Décollement Laminaire dans la Couche-Limite Tridimensionelle). E. A. Eichelbrenner and A. Oudart. November 1956. 9p. diagrs. Translation from Recherche Aeronautique, no. 40, July-August, 1954, p. 3-5. (Request N-49904*)

The criteria of laminar separation of the three-dimensional boundary layer considered up till now have as general form $\left(\frac{\partial v^*}{\partial n}\right)_p = 0^{1,2}$ with v^* being the component of the velocity v within the boundary layer along a determined direction. This general form permits arriving at a condition with immediate physical significance. Thus it is possible to compare a criterion given by Gruschwitz with one proposed by Sears, in the particularly simple case of an elliptic cylinder in oblique approach flow. This comparison leads to a rejection of the criterion of Gruschwitz in favor of that of Sears which requires, however, an extension.

THE PIPE WIND TUNNEL. (Der Rohrwindkanal). Hubert Ludwieg. December 1956. 27p. diagrs., tab. Translation from Zeitschrift für Flugwissenschaften, v. 3, no. 7, 1955, p. 206-216. (Request N-49932*)

The possibility of employing less expensive methods for solving the problems of large and costly wind tunnels is investigated. The demand of the operators of wind tunnels for ever increasing Reynolds numbers and Mach numbers which is the cause of the enormous increase in costs is dealt with first. The possibility of satisfying this requirement by a less costly method is investigated and previous attempts in this direction are mentioned. These investigations lead to a suggestion for the design of a new type of wind tunnel which deviates greatly from conventional types and which, in the opinion of the author, is suitable for solving a great many of the aerodynamic problems at considerably reduced costs. Finally, the technique of testing required for this new type of wind tunnel is briefly discussed.

DAMPING IN ROLL OF A MISSILE CONFIGURATION WITH A MODIFIED TRIANGULAR WING AND A CRUCIFORM TAIL AT A MACH NUMBER OF 1.52. Richard Scherrer and David H. Dennis. March 6, 1951. 23p. diagrs., photo., tab. (NACA RM A51A03)

The damping-in-roll stability derivatives of a missile configuration and of its components were determined both theoretically and experimentally at a Mach number of 1.52. The damping of the cruciform-tail-body combination was 86 percent of the theoretical value and the damping of the wing-body-combination was 67 percent of the theoretical value. The damping of the complete configuration was not equal to the sum of the derivatives of its components because of the effect of the wing downwash on the damping of the tail.

NACA RM A52A14

THEORETICAL INVESTIGATION OF THE STABILITY AT NEGATIVE STATIC MARGINS OF A SUPERSONIC MISSILE WITH AN AUTOPILOT SENSITIVE TO PITCH ANGLE AND PITCHING VELOCITY. Henry A. Cole, Jr., and Marvin Abramovitz. March 1952. 28p. diagrs., tab. (NACA RM A52A14)

Stability charts covering a range of small positive and negative static margins are presented for a supersonic missile with an autopilot sensitive to angle of pitch and rate of pitch. Emphasis is placed on the stability at negative static margins as affected by autopilot components, gain settings, time lags, and natural frequencies. Assumptions to simplify the characteristic stability equation are also presented.

NACA RM E50A09

PERFORMANCE OF HIGH-PRESSURE-RATIO AXIAL-FLOW COMPRESSOR USING HIGHLY CAMBERED NACA 65-SERIES BLOWER BLADES AT HIGH MACH NUMBERS. Charles H. Voit, Donald C. Guentert, and James F. Dugan. March 28, 1950. 22p. diagrs., photos., tabs. (NACA RM E50A09)

A complete stage of an axial-flow compressor was designed and built to investigate the possibility of obtaining a high pressure ratio with an acceptable efficiency through the use of the optimum combination of high blade loading and high relative inlet Mach number. Overall stage performance was investigated over a range of flows at equivalent tip speeds of 418 to 836 feet per second. At design speed (836 ft/sec), a peak total-pressure ratio of 1.445 was obtained with an adiabatic efficiency of 0.89. For design angle of attack at the mean radius, a total-pressure ratio of 1.392 was obtained.

NACA RM E51A24

IGNITION-ENERGY REQUIREMENTS IN A SINGLE TUBULAR COMBUSTOR. Hampton H. Foster. March 27, 1951. 27p. diagrs., tab. (NACA RM E51A24)

Minimum spark energy requirements for ignition in a single tubular combustor were investigated for three fuels of different volatility. A spark energy of about 1.5 joules provided satisfactory ignition at sea-

DECLASSIFIED NACA RESEARCH REPORTS

level engine cranking conditions at an ambient temperature of -60° F for the fuels investigated. About 10 joules provided satisfactory ignition at inlet conditions close to the steady-state burning limits of the combustor at low and intermediate air-flow rates. The ignition-energy requirements at both sea-level and altitude conditions decreased with an increase in fuel volatility.

NACA RM E53A02

INFLUENCE OF END PLATES ON LIFT AND FLOW FIELD OF A CANARD-TYPE CONTROL SURFACE AT A MACH NUMBER OF 2.00. George A. Wise. March 1953. 14p. photos., diagrs. (NACA RM E53A02)

The influence of triangular-shaped end plates on the lift and the flow field of a canard-type control surface mounted on a symmetrical fuselage was investigated in the Lewis 8- by 6-foot supersonic wind tunnel at a Mach number of 2.00, body angle of attack of 2°, and control-surface deflection angles of 3°, 6°, 8°, and 10°. The investigation demonstrated that the addition of end plates to a canard-type control surface increased its lift and rearranged the single vortex into a two-vortex system. Perforating the end plates reduced these effects and resulted in a decrease in lift and a change in the flow-field characteristics.

NACA RM E53H24

AIR-FLOW CHARACTERISTICS OF BRAZED AND ROLLED WIRE FILTER CLOTH FOR TRANSPIRATION-COOLED AFTERBURNERS. William K. Koffel. October 1953. 55p. diagrs., photos., tabs. (NACA RM E53H24)

An experimental investigation was made of the permeability and air-flow uniformity of wire filter cloth for application of transpiration cooling to afterburner combustion-chamber walls. Permeability coefficients in the desired range of 10^{-8} to 10^{-9} square inch for transpiration cooling of afterburner combustion chamber walls were obtained by combined brazing and rolling of the wire cloth. Thickness variations of ±0.0003 inch due to rolling tolerances in combination with initial nonuniformities in the air-flow passages through the wire cloth as woven were largely responsible for localized variations in air-flow uniformity within a given sheet of brazed and rolled wire cloth. Data are presented on the effect of oxidation of the brazing alloy on the pressure-square difference per unit thickness after periods of exposure up to 7 hours at temperatures up to 1560° R. Data are also presented on the effects of brazing and rolling on the short-time ultimate tensile strengths at temperatures up to 1460° R. An afterburner having a porous combustion-chamber wall fabricated from brazed and rolled wire cloth was still in serviceable condition after 4 hours and 10 minutes of afterburning at fuel-air ratios from about 0.030 to 0.050.

NACA RM E55A05

EFFECT OF FLIGHT SPEED ON DYNAMICS OF A TURBOPROP ENGINE. S. Nakanishi, R. T. Craig, and D. B. Wile. April 1955. 40p. diagrs., photo., tabs. (NACA RM E55A05)

An altitude-wind-tunnel investigation of the dynamics of a turboprop engine using approximate step inputs of fuel flow and blade angle was conducted at a simulated altitude of 35,000 ft over a range of flight Mach numbers from 0.15 to 0.5. The generalized time constant of the engine-propeller combination varied with Mach number and power level. Steady-state propeller characteristics were useful in predicting the time constant, and values of the time constant obtained from blade-angle disturbances agreed well with predicted values.

NACA RM E55A21

ENGINE PERFORMANCE OF PRECISION-FORGED, ELECTRO-POLISHED AND MACHINED BLADES OF NIMONIC 80 AND 80A ALLOYS. Paul F. Sikora and James R. Johnston. April 1955. 27p. diagrs., photos., tabs. (NACA RM E55A21)

An investigation of Nimonic 80 and Nimonic 80A turbine blades was conducted in a J33-9 turbojet engine to determine the effect of electropolishing blades and machining blades from oversize forgings. The results are as follows: (1) electropolishing did not improve the engine life of the blades; (2) machining from oversize blades did not improve the engine life of the blades.

NACA RM E55A28

INTERFEROMETRIC OBSERVATION OF FLOW ABOUT AN ISENTROPIC (REVERSE PRANDTL-MEYER STREAMLINE) COMPRESSION WEDGE AT MACH 3.0. James F. Connors, Richard R. Woollett, and Robert E. Blue. March 1955. 12p. diagrs., photos. (NACA RM E55A28)

A map of constant-density contour lines was made of the flow field about a wedge designed to produce a focussed isentropic compression with a static-pressure rise equal to that across a normal shock at free-stream Mach number. A strong-branch-shock configuration resulted. The predicted and experimental modifications of the flow due to boundary-layer displacement effects agreed rather well. By assuming the vortex sheet analogous to a blunt body, some correlation between experiment and theoretical estimates for detached waves was obtained.

NACA RM E55L06

EFFECTS OF A STRAIGHTENING OPERATION ON PERFORMANCE OF INCONEL 550 BUCKETS. C. A. Gyorgak, J. R. Johnston, and J. W. Weeton. February 1956. 24p. diagrs., photos., tabs. (NACA RM E55L06)

An investigation of the effects of straightening of Inconel 550 buckets showed that stress-rupture life was reduced and atypical microstructures were observed in buckets that were straightened and aged. A flash solution treatment given to straightened buckets caused recovery of stress-rupture life and normal microstructure. The engine life of the Inconel 550 buckets was not seriously affected by the straightening operation used in this investigation.

NACA RM E55L06a

ENGINE PERFORMANCE OF OVERTEMPERATURE HEAT-TREATED S-816 BUCKETS. R. A. Signorelli, F. B. Garrett, and J. W. Weeton. March 1956. 26p. diagrs., tabs. (NACA RM E55L06a)

S-816 buckets heat-treated at temperatures above bucket operating temperature were run in a J33-9 turbojet engine. Results indicate that short-time overtemperature heat treatments ranging from 1550° to 2350° F changed stress-rupture properties but did not reduce bucket life.

NACA RM L50A31a

INVESTIGATION OF THE NACA 4-(0)(03)-045 TWO-BLADE PROPELLER AT FORWARD MACH NUMBERS TO 0.925. Melvin M. Carmel and Joseph R. Milillo. March 14, 1950. 29p. diagrs., photo., tab. (NACA RM L50A31a)

The paper presents propeller characteristics for the NACA 4-(0)(03)-045 two-blade propeller for forward Mach numbers to 0.925 and blade angles from 20° to 65°. A comparison of results for this propeller with those for the NACA 4-(0)(08)-045 propeller is presented to show the effect of section thickness ratio on propeller performance. A comparison of this propeller with a propeller using highly swept sections (NACA 4-(4)(06)-057-45A) is also presented in order to indicate whether thickness ratio or sweep is the more effective means of obtaining relatively high efficiencies at transonic speeds.

NACA RM L52A10

RECENT DATA ON CONTROLS. David G. Stone. January 1952. 18p. diagrs. (NACA RM L52A10)

Recent information is presented on flap-type and spoiler controls for use on swept wings (both rigid and flexible), methods for balancing trailing-edge flaps, and the characteristics of some all-movable tails. Comparison of these experimental results from various test facilities shows the effectiveness of flaps and spoilers on swept wings; effectiveness of balance devices such as tabs, horns, and overhangs; and characteristics of all-movable tails of delta and swept plan forms.

NACA RM L52A15

CHARACTERISTICS OF SWEPT WINGS AT HIGH SPEEDS. Charles J. Donlan and Joseph Weil. January 1952. 19p. diagrs. (NACA RM L52A15)

In this paper are presented some of the results of recent swept-wing investigations undertaken by the NACA to determine the effects of thickness and thickness distribution, camber and twist, nose-flap deflection, and devices or "fixes" for improving the wing pitching-moment characteristics at high lift coefficients.

NACA RM L52A31

LONGITUDINAL STABILITY AND DRAG CHARACTERISTICS AT MACH NUMBERS FROM 0.70 TO 1.37 OF ROCKET-PROPELLED MODELS HAVING A MODIFIED TRIANGULAR WING. Rowe Chapman, Jr., and John D. Morrow. May 1952. 35p. diagrs., photos., tab. (NACA RM L52A31)

Longitudinal-stability and drag tests were made using rocket-propelled models having a modified triangular wing. The wing had a leading-edge sweep of 57.08°, an aspect ratio of 2.53, and a root-section thickness of 3.7 percent. Aerodynamic coefficients for lift, drag, static stability, and damping are presented for the Mach number range of 0.70 to 1.37.

NACA RM L53K20a

COMPARISON OF EXPERIMENTAL HYDRODYNAMIC IMPACT LOADS AND MOTIONS FOR A V-STEP AND A TRANSVERSE-STEP HYDRO-SKI. Robert W. Miller. February 1954. 14p. diagrs., tabs. (NACA RM L53K20a)

A comparison is presented of the hydrodynamic impact loads and motions encountered in testing a V-step and a transverse-step flat-bottom hydro-ski having beam loadings of about 4.5 in fixed-trim smooth-water impacts at various velocities and flight-path angles. The comparisons are presented as plots of the nondimensional load, draft, vertical velocity, and time coefficients against flight-path angle at contact. The results show that the V-step reduces maximum impact loads up to 50 percent, increases the depth of penetration, and changes some of the vertical velocity and time characteristics of the hydro-ski.

NACA RM L55A07

EXPERIMENTAL DETERMINATION OF THE AERODYNAMIC DERIVATIVES ARISING FROM ACCELERATION IN SIDESLIP FOR A TRIANGULAR, A SWEPT, AND AN UNSWEPT WING. Donald R. Riley, John D. Bird, and Lewis R. Fisher. March 1955. 27p. diagrs., photos. (NACA RM L55A07)

Angle-of-attack variations of the aerodynamic derivatives arising from acceleration in sideslip which were obtained from a low-speed wind-tunnel investigation are presented for a 60° triangular, a 45° sweptback, and an unswept wing. Data were obtained by forcing the wings to perform a lateral plunging oscillation across the jet of the 6- by 6-foot test section of the Langley stability tunnel. Static-lateral-stability derivatives obtained from static sideslip tests are compared with values obtained from the oscillation tests. Some indication of the effect of changes in frequency of oscillation is also presented.

NACA RM L55A18

EXPERIMENTAL FLUTTER INVESTIGATION OF A THIN UNSWEPT WING AT TRANSONIC SPEEDS. George L. Pratt. April 1955. 24p. diagrs., tabs. (NACA RM L55A18)

Zero-lift experimental flutter data have been obtained in the Mach number range from 0.75 to 1.25 on a 1.5-percent-thick, untapered, unswept solid

DECLASSIFIED NACA RESEARCH REPORTS

steel wing having hexagonal airfoil sections and aspect ratios of 3.75 and 4.00. The experimental results have been normalized by utilizing flutter speeds calculated by a strip-analysis procedure with two-dimensional aerodynamic coefficients for incompressible flow. For one case the results have been normalized by taking into account three-dimensional aerodynamic effects.

NACA RM L55E16b

A STUDY OF THE CORRELATION BETWEEN FLIGHT AND WIND-TUNNEL BUFFETING LOADS. Wilber B. Huston, A. Gerald Rainey, and Thomas F. Baker. July 1955. 15p. diagrs. (NACA RM L55E16b)

Comparison of the buffet loads measured on wind-tunnel models with loads measured in flight indicates that, during the course of the regular wind-tunnel testing program on a model, a simple strain-gage measurement can be made which can be used to predict the wing buffet loads on the airplane. The comparison is made for airplanes with swept and with unswept wings. The relation between buffet loads on a model and buffet loads on an airplane in flight is discussed from the standpoint of the input-output relationships of generalized harmonic analysis. The analysis of buffet load measurements on a statistical basis is outlined.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A54B08a

INVESTIGATION OF THE EFFECTS OF PROFILE SHAPE ON THE AERODYNAMIC AND STRUCTURAL CHARACTERISTICS OF THIN, TWO-DIMENSIONAL AIRFOILS AT SUPERSONIC SPEEDS. Elliott D. Katzen, Donald M. Kuehn, and William A. Hill, Jr. May 1954. 59p. diagrs., tabs. (NACA RM A54B08a)

The effects of thickness, trailing-edge bluntness, boattailing, and forward profile were determined. The results indicated that available theoretical methods were adequate for calculating the lift and pitching moment of the airfoils under all conditions of the test. The theoretical methods for calculating foredrag and correlation curves for estimating base pressure were adequate for predicting the total drag when the position of transition was known.

NACA RM A54B09

TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF THE EFFECTS OF VARIOUS WING MODIFICATIONS ON THE LONGITUDINAL CHARACTERISTICS OF TWO TRIANGULAR-WING AIRPLANE MODELS WITH AND WITHOUT HORIZONTAL TAILS. David G. Koenig. April 1954. 29p. diagrs., tabs. (NACA RM A54B09)

An investigation was made with the objective of eliminating destabilizing changes of pitching moment through the use of wing modifications for two airplane models having triangular wings of aspect ratios 2 and 3. The models were tested with horizontal tails located above the extended wing chord plane as well as with the tails off. Chord extensions, fences, and combinations of these were the principal wing modifications considered. The unfavorable stability changes of the basic models at high lift coefficients were not entirely eliminated by the modifications tested. However, considerable improvement was obtained for both models with the use of a chord extension in combination with a fence. Reynolds numbers of the investigation were 14.6 and 12.8×10^6 for the models with aspect-ratio-2 and -3 wings, respectively, and the Mach number was 0.13.

NACA RM A55B11

THE STATIC LATERAL AND DIRECTIONAL SUBSONIC AERODYNAMIC CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A TRIANGULAR WING OF ASPECT RATIO 3. Howard F. Savage and Bruce E. Tinling. April 1955. 82p. diagrs., photo., tabs. (NACA RM A55B11)

The effects of vertical-tail size and length on the lateral and directional stability characteristics of both mid- and high-wing airplane arrangements were evaluated. Also evaluated were the directional-control effectiveness of a rudder, and the lateral-control effectiveness of ailerons and of differential deflection of the horizontal tail surfaces. The tests were conducted at a Reynolds number of 2.5 million at Mach numbers from 0.25 to 0.95.

NACA RM A55B14

WIND-TUNNEL INVESTIGATION AT LOW SPEED OF A WING HAVING 63° SWEEPBACK AND A DROOPED TIP. James R. Blackaby. April 1955. 25p. diagrs., photos., tab. (NACA RM A55B14)

The results of low-speed force tests are presented to show the effects of variations of dihedral (droop) of the outer portion of a 63° sweptback semispan wing on the static longitudinal stability characteristics of the wing. Models with both curved and abruptly drooped tips were investigated, and, in addition, the effects of fences and of a leading-edge flap on the outer portion of the wing were measured.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E50B14

FREE-FLIGHT PERFORMANCE OF 16-INCH-DIAMETER SUPERSONIC RAM-JET UNITS. II - FIVE UNITS DESIGNED FOR COMBUSTION-CHAMBER-INLET MACH NUMBER OF 0.16 AT FREE-STREAM MACH NUMBER OF 1.60 (UNITS B-1, B-2, B-4, AND B-5). Wesley E. Messing and Scott H. Simpkinson. May 5, 1950. 44p. diagrs., photos., tab. (NACA RM E50B14)

Free-flight performance of five 16-inch-diameter ram-jet units was determined over range of free-stream Mach numbers of 0.50 to 1.86 and gas total-temperature ratios between 1.0 and 6.1. Time histories of performance data are presented for each unit. Correlations illustrate effect of free-stream Mach number and gas total-temperature ratio on diffuser total-pressure recovery, net-thrust coefficient, and external drag coefficient. One unit had smooth steady burning throughout the entire flight and encountered a maximum free-stream Mach number of 1.86 with a net acceleration of approximately 4.2 g's.

NACA RM E50D07

FREE-FLIGHT PERFORMANCE OF 16-INCH-DIAMETER SUPERSONIC RAM-JET UNITS. III - FOUR UNITS DESIGNED FOR COMBUSTION-CHAMBER-INLET MACH NUMBER OF 0.245 AT FREE-STREAM MACH NUMBER OF 1.8 (UNITS D-1, D-2, D-3, AND D-4). John H. Disher and Leonard Rabinowitz. June 28, 1950. 41p. diagrs., photos. (NACA RM E50D07)

Performance of four 16-inch-diameter ram-jet units was determined at free-stream Mach numbers of 0.49 to 1.78 over range of gas total-temperature ratios of 1.0 to 6.1. Time histories of each flight and data on thrust, drag, diffuser efficiency, and combustion are presented. A maximum thrust coefficient of 0.88 and a maximum net acceleration of 5.13 g's were observed for the four units.

#NACA RM E50H15, by Rabinowitz and North

NACA RM E50L18

FREE-FLIGHT PERFORMANCE OF 16-INCH-DIAMETER SUPERSONIC RAM-JET UNITS. IV - PERFORMANCE OF RAM-JET UNITS DESIGNED FOR COMBUSTION-CHAMBER-INLET MACH NUMBER OF 0.21 AT FREE-STREAM MACH NUMBER OF 1.6 OVER A RANGE OF FLIGHT CONDITIONS. Leonard Rabb and Warren J. North. February 26, 1951. 46p. diagrs., photos., tab. (NACA RM E50L18)

The performance of four 16-inch-diameter ram-jet units was determined at free-stream Mach numbers of 0.43 to 1.83 for a range of gas total-temperature ratios from 1.0 to 4.8. The effects of free-stream Mach number and gas total-temperature ratio on diffuser pressure recovery, external drag coefficient, and thrust coefficient are correlated. Combustion data with stability limits are also presented.

NACA RM E52B21

AERODYNAMIC INTERFERENCE EFFECTS ON NORMAL AND AXIAL FORCE COEFFICIENTS OF SEVERAL ENGINE-STRUT-BODY CONFIGURATIONS AT MACH NUMBERS OF 1.8 AND 2.0. Emil J. Kremzier and Murray Dryer. April 1952. 35p. diagrs., tab. (NACA RM E52B21)

An investigation to determine aerodynamic interference effects on normal and axial-force characteristics of several engine-strut-body combinations was conducted over range of angles of attack from 0° to 10° at Mach numbers of 1.8 and 2.0. Average Reynolds number based on body length was 28×10^{6}. Data are presented in the form of interference factors and indicate decreases in axial force and normal force curve slope with decreasing strut length. Decreases in axial force were also noted with rearward movement of engines. Theoretical evaluation of aerodynamic interference effects indicated a need for further refinements in the method of evaluation. A short discussion on the configuration lift-drag ratio is also included.

NACA RM E52C17

EXPERIMENTAL INVESTIGATION OF A CONSERVATIVELY DESIGNED TURBINE AT FOUR ROTOR-BLADE SOLIDITIES. Jack A. Heller, Rose L. Whitney, and Richard H. Cavicchi. July 1952. 25p. diagrs., photo., tab. (NACA RM E52C17)

The overall performance of a conservatively designed turbine suitable for the last stage of a multistage turbine is presented. The turbine was investigated at four rotor-blade solidities ranging from 0.85 to 2.27. The 44-blade-rotor turbine, having a solidity of 1.56, yielded the best efficiency over most of the range of investigation. The value of maximum brake internal efficiency was 0.895. The efficiency at the design point was 0.89. A relatively flat curve of maximum brake internal efficiency was found over most of the range of solidities investigated.

NACA RM E52J03

PERFORMANCE OF PURE FUELS IN A SINGLE J33 COMBUSTOR. I - FIVE LIQUID HYDROCARBON FUELS. Jerrold D. Wear and Ralph T. Dittrich. November 1952. 43p. diagrs., tabs. (NACA RM E52J03)

Investigations of several pure hydrocarbon fuels were conducted in a J33 single combustor at several inlet-air conditions to determine possible relations between combustor performance and fuel physical or fundamental combustion properties. The fuels investigated were isooctane, cyclohexane, methylcyclohexane, n-heptane, and benzene. Three combustor performance parameters were used to obtain a performance order among the fuels. Of the several fuel properties considered, maximum burning velocity best correlated with fuel performance, indicating an approximately linear increase in performance of the fuels with an increase in burning velocity.

NACA RM E53A16

INVESTIGATION OF DISTRIBUTION OF LOSSES IN A CONSERVATIVELY DESIGNED TURBINE. Rose L. Whitney, Jack A. Heller, and Cavour H. Hauser. March 1953. 26p. diagrs., photo. (NACA RM E53A16)

A primary objective of turbine research is to obtain information that will aid in the design of gas turbines for any given application with minimum losses. As part of a program to obtain such information, flow surveys downstream of both the stator and the rotor of an experimental turbine were made in order to obtain detailed information about the flow conditions and the losses within the machine. The single-stage, low-radius-ratio turbine studied is relatively conservative in design, having low rotor-inlet relative Mach number, low turning angle, and high reaction at the rotor-root section. Surveys of the flow conditions and of the losses within the turbine are presented. The measured overall losses are analyzed in order to approximate the magnitudes of the various components of loss. It was found that the major losses in the turbine were in the rotor near the blade extremities. The losses in the tip region were considerably greater than those near the hub. The existence of secondary flows at the exit of both the stator and the rotor was indicated by the presence of low-velocity cores near both the hub and the tip sections. Analysis of the losses by an empirical method indicated that the rotor-profile and the tip-clearance losses are 31 and 9 percent of the adjusted measured total rotor loss, respectively. The remaining 60 percent loss was attributed to secondary flows.

NACA RM L51B05

THE EFFECT OF THICKNESS RATIO ON SECTION THRUST DISTRIBUTION AS DETERMINED FROM A STUDY OF WAKE SURVEYS OF THE NACA 4-(0)(03)-045 AND 4-(0)(08)-045 TWO-BLADE PROPELLERS UP TO FORWARD MACH NUMBERS OF 0.925. Daniel E. Harrison and Joseph R. Milillo. April 5, 1951. 62p. diagrs., photo., tabs. (NACA RM L51B05)

Section-thrust-coefficient data are presented for forward Mach numbers to 0.925 for the NACA 4-(0)(03)-045 propeller for blade angles of 40° to 65° and for the NACA 4-(0)(08)-045 propeller for blade angles of 50° to 65°. The results indicate the effect of blade thickness ratio and forward Mach number on thrust distribution.

NACA RM L53B02

EFFECT OF LEADING-EDGE CHORD-EXTENSIONS ON THE AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK WING-FUSELAGE COMBINATION AT MACH NUMBERS OF 0.40 TO 1.03. F. E. West, Jr., George Liner, and Gladys S. Martz. April 1953. 40p. diagrs., photo. (NACA RM L53B02)

A wind-tunnel investigation has been made to determine the effect of leading-edge chord-extensions on the aerodynamic characteristics of a sting-supported sweptback wing-fuselage combination at Mach numbers from 0.40 to 1.03. The wing had 45° sweep, aspect ratio of 4, taper ratio of 0.6, and NACA 65A006 airfoil sections. The span, chord length, and droop angles of the chord-extensions were varied. In general, the chord-extensions were effective in improving the variation of pitching moment with lift, and the lift characteristics, and lift-drag ratios at lift coefficient above 0.40 or 0.50. The gain in lift-drag ratio decreased with increasing Mach number.

NACA RM L53B04

AN INVESTIGATION AT TRANSONIC SPEEDS OF THE EFFECTS OF FENCES, DROOPED NOSE, AND VORTEX GENERATORS ON THE AERODYNAMIC CHARACTERISTICS OF A WING-FUSELAGE COMBINATION HAVING A 6-PERCENT-THICK, 45° SWEPTBACK WING. Gerald Hieser. March 1953. 26p. diagrs., photos. (NACA RM L53B04)

Lift, drag, and pitching-moment characteristics are presented at Mach numbers from 0.60 to 1.03 for a 45° sweptback wing-fuselage combination with fences at the 0.65 semispan station, drooped nose of the outer 0.35 semispan, and combination fences and drooped nose. Lift and pitching-moment data are given for the model with vortex generators installed at the wing leading edge and at the 0.15 chord station. The results show that an improvement in the pitching-moment characteristics resulted from the fences at Mach numbers from 0.60 to about 0.90 and 1.00. The drooped nose improved the pitch characteristics at Mach numbers of 0.98 and above, and no improvement resulted from the vortex generators.

NACA RM L53B16

EFFECTS OF SLOT SIZE AND GEOMETRY ON THE FLOW IN RECTANGULAR TUNNELS AT MACH NUMBERS UP TO 1.4. William J. Nelson and James M. Cubbage, Jr. April 1953. 43p. diagrs., photos., tab. (NACA RM L53B16)

An investigation has been made of the effects of slot width, depth, shape, and spacing on the center-line pressure distribution in rectangular tunnels of constant cross section with several height-to-width ratios. Results are presented in the form of center-line static-pressure distributions and calculated static-pressure and angle-of-flow distributions along the slotted boundary. The latter was accomplished by the method of characteristics using the center-line pressure distribution as a starting point and assuming isentropic flow throughout the length of the tunnel. The data show that transonic flows with a maximum deviation in Mach number less than ± 0.01 can be generated in a rectangular tunnel with fixed-geometry slots for Mach numbers up to 1.4, the limit of the tests. It is also shown that changes in the effective free area ratio of the boundary and in the length of the tapered slot opening cause large changes in axial pressure distribution. With a given slot configuration more uniform flows were obtained in tunnels of large height-width ratio.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53B25a

WIND-TUNNEL INVESTIGATION OF THE STATIC LATERAL STABILITY CHARACTERISTICS OF WING-FUSELAGE COMBINATIONS AT HIGH SUBSONIC SPEEDS. TAPER-RATIO SERIES. James W. Wiggins and Paul G. Fournier. April 1953. 25p. diagrs., photos. (NACA RM L53B25a)

This paper presents the aerodynamic characteristics in sideslip of wing-fuselage combinations. The wings have a sweep angle of 45° at the quarter-chord line, aspect ratio of 4, taper ratios of 0.3, 0.6, and 1.0, and an NACA 65A006 airfoil section. The tests covered a Mach number range from 0.4 to 0.95, a Reynolds number range from 1.7×10^6 to 3.2×10^6, and an angle-of-attack range from -3° to 24°.

NACA RM L54B03

A LOW-SPEED INVESTIGATION OF THE AERODYNAMIC, CONTROL, AND HINGE-MOMENT CHARACTERISTICS OF TWO TYPES OF CONTROLS AND BALANCING TABS ON A LARGE-SCALE THIN DELTA-WING—FUSELAGE MODEL. Marvin P. Fink and Bennie W. Cocke. March 1954. 69p. diagrs., photo., tabs. (NACA RM L54B03)

Low-speed longitudinal and lateral control and hinge-moment characteristics of a 60° delta-wing—fuselage combination having an NACA 65A003 airfoil section are presented. Effects of Reynolds number, inboard flap deflection, and control-tip-radius modification are shown for half-delta and horn-balance-type controls. A limited investigation of balancing tabs on the horn-balance-type control was also included.

NACA RM L54B17

LOW-SPEED LONGITUDINAL STABILITY AND LATERAL-CONTROL CHARACTERISTICS OF A MODEL OF A 40° SWEPT-WING FIGHTER-TYPE AIRPLANE AT A REYNOLDS NUMBER OF 9×10^6. Thomas V. Bollech and H. Neale Kelly. February 1956. 149p. diagrs., photo., tabs. (NACA RM L54B17)

An investigation was conducted in the Langley 19-foot pressure tunnel on a model of a 40° swept-wing fighter airplane to determine modifications which would eliminate the pitch-up that occurred near maximum lift during flight tests of the airplane. The effects of high-lift and stall-control devices, horizontal-tail locations, external stores, and various wing-root inlets on the longitudinal stability characteristics of the model were investigated. For the most part, these tests were conducted at a Reynolds number of 9.0×10^6 and a Mach number of 0.19. All tests were made over an angle-of-attack range from -4° to 31°.

NACA RM L54C29

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE STABILITY CHARACTERISTICS OF A COMPLETE MODEL HAVING SWEPTBACK-, M-, W-, AND CRANKED-WING PLAN FORMS AND SEVERAL HORIZONTAL-TAIL LOCATIONS. Kenneth W. Goodson and Robert E. Becht. May 1954. 72p. diagrs., photo. (NACA RM L54C29)

The present paper presents results of an investigation to determine the effect of composite wing plan forms on the high-speed (M = 0.80 to 0.92) longitudinal and lateral stability characteristics of a complete model having various horizontal-tail locations. The composite M-, W-, and cranked-wing plan forms were obtained by modifying the design of the basic wing having an aspect ratio of 4.0, a taper ratio of 0.3, and 45° of sweepback. Some data are also presented for the swept wing with a 10-percent-mean-aerodynamic-chord slat located on the outboard 35 percent of the swept-wing semispan.

NACA RM L54D15a

AERODYNAMIC CHARACTERISTICS AT SMALL SCALE AND A MACH NUMBER OF 1.38 OF UNTAPERED WINGS HAVING M AND W PLAN FORMS. William B. Kemp, Jr. June 1954. 17p. diagrs., tab. (NACA RM L54D15a)

An investigation was made at a Mach number of 1.38 and a Reynolds number of 390,000 to determine the supersonic aerodynamic characteristics of several wings having M and W plan forms. The wings had panel sweep angles of 60°, NACA 65A006 airfoil sections, and a basic aspect ratio of 4 and were untapered. Several tip plan-form modifications were investigated. The results are compared with approximately equivalent results for sweptback wings.

NACA RM L56A10

LOW-SPEED LONGITUDINAL AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK WING WITH DOUBLE SLOTTED FLAPS. Rodger L. Naeseth. April 1956. 31p. diagrs., tabs. (NACA RM L56A10)

A low-speed investigation has been made to determine the effect of 0.35-semispan double slotted flaps consisting of a 0.213-wing-chord main flap and either a 0.500-flap-chord vane or a 0.266-flap-chord vane on the aerodynamic characteristics of a 45° sweptback wing. The wing had an aspect ratio of 3.7, a taper ratio of 0.41, and a streamwise thickness ratio of 0.086. The Reynolds number was 1.8×10^6. Lift-coefficient increments for the double slotted flaps at an angle of attack of 0° were 0.67 at a flap deflection of 80° for the flap with 0.500-flap-chord vane and 0.55 at a flap deflection of 66° for the flap with 0.266-flap-chord vane. Maximum lift was about the same for the two flaps. Tests with either or both of the slots blocked were also made.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1242

TRANSONIC FLOW PAST CONE CYLINDERS. George E. Solomon, California Institute of Technology. 1955. ii, 16p. diagrs., photos. (NACA Rept. 1242. Supersedes TN 3213)

Experimental results are presented for transonic flow past cone-cylinder, axially symmetric bodies. The drag coefficient and surface Mach number are studied as the free-stream Mach number is varied and, wherever possible, the experimental results are compared with theoretical predictions. Interferometric results for several typical flow configurations are shown and an example of shock-free supersonic-to-subsonic compression is experimentally demonstrated. The theoretical problem of transonic flow past finite cones is discussed briefly and an approximate solution of the axially symmetric transonic equations, valid for a semi-infinite cone, is presented.

NACA Rept. 1285

SUMMARY OF DERIVED GUST VELOCITIES OBTAINED FROM MEASUREMENTS WITHIN THUNDERSTORMS. H. B. Tolefson. 1956. ii, 7p. diagrs., tabs. (NACA Rept. 1285. Supersedes TN 3538)

Available measurements of the derived gust velocities within thunderstorms are summarized for altitudes from 5,000 to 34,000 feet. The results indicate that the intensity of the derived gust velocity is essentially constant up to altitudes of 20,000 feet and that an approximate 10-percent reduction in the gust intensity occurs for altitudes from 20,000 to 30,000 feet.

NACA RM 57A30

PROBLEM OF SLIP FLOW IN AERODYNAMICS. Robert E. Street, University of Washington. March 1957. 29p. (NACA RM 57A30)

The present status of theory in the field of slip-flow aerodynamics was investigated and it was concluded that the Navier-Stokes equations of motion together with first-order velocity slip and temperature jump at any boundary are sufficient insofar as experimental confirmation is available. The use of the Burnett terms in the equations of motion as well as second-order terms in boundary conditions does not seem justified, at least for semirarefied gas flows.

NACA RM E56K30

SURVEY OF MICROSTRUCTURES AND MECHANICAL PROPERTIES OF OVERTEMPERATURED S-816 TURBINE BUCKETS FROM J47 ENGINES. S. Floreen and R. A. Signorelli. March 1957. 41p. diagrs., photos., tabs. (NACA RM E56K30)

Most buckets overtemperatured in service had overaged microstructures. Similar microstructures were observed in some new buckets and in new buckets heated to 1500° F for 50 hours. Therefore, an overaged microstructure is not proof of overtemperature. A partially solutioned microstructure is proof of overtemperature. Partially solutioned buckets had longer rupture lives than overaged ones. Examination of new buckets indicates that scatter in bucket performance may be due to fabricating variables.

NACA RM E57A29a

EVALUATION OF THE USE OF ELECTRICAL RESISTANCE FOR DETECTING OVERTEMPERATURED S-816 TURBINE BLADES. Leonard Robins. March 1957. 22p. diagrs., photos., tabs. (NACA RM E57A29a)

The effects of fabrication variables, dimensional tolerances, and time at various overtemperatures on the resistance of S-816 turbine blades were evaluated. The resistance changes caused by overtemperature were within the scatter band of the resistances of new turbine blades and were less than the maximum variation due to dimensional tolerances. As a consequence, overtemperature is impossible to detect without a knowledge of the blade resistance history. Even if the resistance of the blade prior to operation were known, only severe overtemperatures could be detected.

NACA TN 3835

A STUDY OF SPRAYS FORMED BY TWO IMPINGING JETS. Marcus F. Heidmann, Richard J. Priem, and Jack C. Humphrey. March 1957. 32p. diagrs., photos., tab. (NACA TN 3835. Supersedes TN 2349)

The spray pattern developed by two impinging liquid jets over a velocity range of 5 to 100 feet per second is photographically and numerically described. Surface tension and viscosity effects on the spray pattern are presented for low jet velocities. At high velocities the spray consists of waves of drops. For water sprays the frequency of these waves increased with increasing injection velocity and decreasing impingement angle. Jet diameter and jet length before impingement had a negligible effect on wave frequency. Characteristics of the jets prior to impingement were also studied.

NACA TN 3846

EXPERIMENTAL INVESTIGATION OF THE FORCES AND MOMENTS DUE TO SIDESLIP OF A SERIES OF TRIANGULAR VERTICAL- AND HORIZONTAL-TAIL COMBINATIONS AT MACH NUMBERS OF 1.62, 1.93, AND 2.41. Donald E. Coletti. March 1957. 32p. diagrs., photo., tabs. (NACA TN 3846. Supersedes RM L54G01)

An experimental investigation was made at Mach numbers of 1.62, 1.93, and 2.41 of the sideslip derivatives for tail arrangements consisting of a triangular vertical tail attached symmetrically to a triangular horizontal tail. Comparisons are made with the theoretical derivatives presented in NACA TN 3071 and NACA TN 2412.

NACA TN 3869

INVESTIGATION OF SEPARATED FLOWS IN SUPERSONIC AND SUBSONIC STREAMS WITH EMPHASIS ON THE EFFECT OF TRANSITION. Dean R. Chapman, Donald M. Kuehn, and Howard K. Larson. March 1957. 109p. diagrs., photos. (NACA TN 3869)

Experimental and theoretical research has been conducted on flow-separation phenomena associated with steps, bases, compression corners, curved surfaces, shock-wave boundary-layer reflections, and configurations involving leading-edge separation. Results were obtained from pressure-distribution measurements, shadowgraph observations, high-speed motion pictures, and oil-film studies. The maximum scope of measurement encompassed Mach numbers between 0.4 and 3.6 and length Reynolds numbers between 4,000 and 5,000,000. The principal variable controlling pressure distribution in the various separated flows was found to be the location of transition relative to the reattachment and separation positions.

NACA TN 3876

AN INVESTIGATION AT LOW SPEED OF THE FLOW OVER A SIMULATED FLAT PLATE AT SMALL ANGLES OF ATTACK USING PITOT-STATIC AND HOT-WIRE PROBES. Donald E. Gault. March 1957. 58p. diagrs., photos., tabs. (NACA TN 3876)

Results are presented from pitot-static and hot-wire-anemometer surveys of the low-speed flow about a simulated flat plate for angles of attack of 2°, 4°, and 6°. Measurements were obtained for a Reynolds number of 4×10^{6}. The data are presented in graphical as well as tabular form. Methods for correcting the mean velocity measurements for the effects of the exceedingly high levels of turbulence encountered during the investigation are presented in appendixes.

NACA TN 3880

MEASUREMENTS OF LIFT FLUCTUATIONS DUE TO TURBULENCE. P. Lamson, California Institute of Technology. March 1957. 38p. diagrs. (NACA TN 3880)

The power spectra of the fluctuating lift of a rigid wing in turbulent flow were measured, the aerodynamic admittance was obtained, and comparisons were made with existing theory. Aspect ratio and span were varied by means of movable end plates.

NACA TN 3912

FLIGHT TESTS OF A MODEL OF A HIGH-WING TRANSPORT VERTICAL-TAKE-OFF AIRPLANE WITH TILTING WING AND PROPELLERS AND WITH JET CONTROLS AT THE REAR OF THE FUSELAGE FOR PITCH AND YAW CONTROL. Powell M. Lovell, Jr., and Lysle P. Parlett. March 1957. 28p. diagrs., photo., tab. (NACA TN 3912)

An investigation of the stability and control of a high-wing transport vertical-take-off airplane with four engines during constant-altitude transitions from hovering to normal forward flight was conducted with a remotely controlled free-flight model. The model had four propellers distributed along the wing with the thrust axes in the wing chord plane. The wing could be rotated to 90° incidence so that the propeller thrust axes were vertical for hovering flight. An air jet at the rear of the fuselage provided pitch and yaw control for hovering and low-speed flight.

NACA TN 3925

PRELIMINARY METALLOGRAPHIC STUDIES OF BALL FATIGUE UNDER ROLLING-CONTACT CONDITIONS. H. Robert Bear and Robert H. Butler. March 1957. 38p. diagrs., photos. (NACA TN 3925)

The metallurgical results produced on balls tested in the rolling-contact fatigue spin rig were studied by metallographic examination. Origin and progression

CURRENT NACA RESEARCH REPORTS

of fatigue failures were observed. These evaluations were made on SAE 52100 and AISI M-1 balls fatigue tested at room temperature (80° F) and 200° to 250° F. Most failures originated subsurface in shear; inclusions, structure changes, and directionalism adversely affected ball fatigue life. Structures in the maximum-shear-stress region of the balls of both materials were stable at room temperature and unstable at 200° to 250° F. Failures were of the same type as those found in full-scale bearings.

NACA TN 3932

AN INVESTIGATION OF HIGH-TEMPERATURE VACUUM AND HYDROGEN FURNACE BRAZING. Walter E. Russell and John P. Wisner. March 1957. 29p. diagrs., photos., tabs. (NACA TN 3932)

The vacuum and the hydrogen brazing of four heat-resistant alloys with two types of high-temperature brazing alloy were investigated. The effect of time at various brazing temperatures on the 1200° F shear strength of joints and on the base-metal tensile strength and elongation was also studied. Brazing techniques for alloys that can be age hardened and that contain titanium and aluminum in a vacuum as well as in dry hydrogen were evaluated.

NACA TN 3936

EXPERIMENTAL INVESTIGATION OF TEMPERATURE FEEDBACK CONTROL SYSTEMS APPLICABLE TO TURBOJET-ENGINE CONTROL. C. E. Hart, L. M. Wenzel, and R. T. Craig. March 1957. 56p. diagrs. (NACA TN 3936)

Temperature - fuel-flow and temperature-area feedback control systems were investigated as means of controlling tailpipe gas temperature of a turbojet engine during transient operation in the high-speed region. Proportional-plus-integral control was used in both systems, but in the temperature-area control system it was necessary to add nonlinear components to the basic proportional-plus-integral control to provide satisfactory transient response to a desired step increase in temperature. Time integrals of temperature-error functions were used as criteria for determining optimum transient response. A description of engine dynamics was obtained from frequency-response data.

NACA TN 3937

A COMPARISON OF TYPICAL NATIONAL GAS TURBINE ESTABLISHMENT AND NACA AXIAL-FLOW COMPRESSOR BLADE SECTIONS IN CASCADE AT LOW SPEED. A. Richard Felix and James C. Emery. March 1957. 46p. diagrs., photo., tabs. (NACA TN 3937. Supersedes RM L53B26a)

Comparative cascade tests of the NGTE (National Gas Turbine Establishment of Great Britain) 10C4/30C50 and NACA 65-($12A_{10}$)10 axial-flow compressor blade sections were conducted in a 5-inch low-speed cascade tunnel at the Langley Laboratory at air-inlet angles of 30°, 45°, and 60° and a solidity of 1.0 by using the porous-wall technique. These NACA data for the NGTE 10C4/30C50 section were also compared with data from NGTE design charts for the same section. British and NACA incompressible cascade force-analysis equations are included.

NACA TN 3939

A THEORETICAL AND EXPERIMENTAL STUDY OF PLANING SURFACES INCLUDING EFFECTS OF CROSS SECTION AND PLAN FORM. Charles L. Shuford, Jr. March 1957. 126p. diagrs., photos., tabs. (NACA TN 3939)

A summary is given of the background and present status of pure-planing theory. Data for models having sharp chines have been obtained for a rectangular flat plate and two V-bottom surfaces having constant angles of dead rise of 20° and 40° and also for rectangular-flat-plate surfaces having very slightly rounded chines. The theory presented in NACA Technical Note 3233 for a rectangular flat plate is revised and extended to include triangular flat plates planing with base forward and V-shaped prismatic surfaces having a constant angle of dead rise, horizontal chine flare, or vertical chine strips. The agreement between the results calculated by the proposed theory and the experimental data is satisfactory for engineering calculations of lift and center-of-pressure location.

NACA TN 3949

EXPERIMENTAL INVESTIGATION OF THE OSCILLATING FORCES AND MOMENTS ON A TWO-DIMENSIONAL WING EQUIPPED WITH AN OSCILLATING CIRCULAR-ARC SPOILER. Sherman A. Clevenson and John E. Tomassoni. March 1957. 20p. diagrs., photos. (NACA TN 3949. Supersedes RM L53K18)

Results of a wind-tunnel investigation of the forces, moments, and phase angles on a two-dimensional wing equipped with an oscillating circular-arc spoiler are presented. Schlieren photographs are presented which show the flow over and behind the spoiler. Data for Reynolds numbers from 1.3×10^6 to 6.3×10^6, Mach numbers from 0.2 to 0.82, and reduced frequencies from 0 to 0.92 on the normal-force and pitching-moment coefficients and their respective phase angles referred to spoiler position are indicated.

NACA TN 3951

INVESTIGATION OF THE PLANING LIFT OF A FLAT PLATE AT SPEEDS UP TO 170 FEET PER SECOND. Kenneth W. Christopher. March 1957. 15p. diagrs., photos., tab. (NACA TN 3951)

An experimental investigation was made in the Langley high-speed hydrodynamics facility to determine whether the planing lift coefficient of a flat-bottom planing surface remains constant with increasing speed at the high towing speeds of this facility. No effect of speed was noted for the range of speeds tested. In addition, the data agreed well with that recently obtained in lower speed towing tanks. A brief description of the facility is included.

CURRENT NACA RESEARCH REPORTS

NACA TN 3962

THE EROSION OF METEORS AND HIGH-SPEED VEHICLES IN THE UPPER ATMOSPHERE. C. Frederick Hansen. March 1957. 38p. diagrs., tab. (NACA TN 3962)

Analytic relations for velocity, deceleration, size, and relative magnitude of luminosity of meteors are derived in parametric form. Comparison of the theory with observed meteor behavior indicates that a large fraction of the atmospheric bombardment energy is used in eroding meteor material. Erosion from large, high-speed vehicles in free-molecule flow is calculated and the mass loss is found negligible.

NACA TN 3963

A CORRELATION OF LOW-SPEED, AIRFOIL-SECTION STALLING CHARACTERISTICS WITH REYNOLDS NUMBER AND AIRFOIL GEOMETRY. Donald E. Gault. March 1957. 9p. diagrs., tab. (NACA TN 3963)

Low-speed stalling characteristics of airfoil sections are correlated with Reynolds number and the ordinate at a particular chordwise location. The correlation is appropriate only to airfoils without high-lift devices in flows of very low turbulence and with aerodynamically smooth surfaces.

LOW SPEED WIND TUNNEL TESTS ON PERFORATED SQUARE FLAT PLATES NORMAL TO THE AIRSTREAM: DRAG AND VELOCITY FLUCTUATION MEASUREMENTS. B. G. de Bray. October 1956. 13p. diagrs., tab. RAE Tech.Note Aero 2475. (Ask for N-48156*)

The effects of perforations upon the drag, and velocity fluctuations downstream, of square plates normal to the airstream are described. It is shown that perforations can have a powerful effect upon the level of velocity fluctuations, particularly the low-frequency components, with only a comparatively small reduction in drag coefficient. It is also shown that perforating the central region only of a square plate is as effective in reducing velocity fluctuations as perforating the whole plate while giving a slightly higher drag coefficient than the latter. On the other hand, perforations near the periphery only are less effective.

National Gas Turbine Establishment (Gt. Brit.) REGULARITIES IN CREEP AND HOT-FATIGUE DATA. PART I. A. Graham and K. F. A. Walles. December 1956. 25p. diagrs., tabs. NGTE R. 189. (Ask for N-48160*)

Published experimental results are assembled to support a previously given theory of uniaxial deformation, and the theory is then used to analyze published data on the creep ruture and hot fatigue of engineering materials. The theory enables data for different times and temperatures to be classed together, thereby providing information over a much greater range of times than could practicably be covered by experiments at a single temperature. An underlying numerical pattern common to all the widely different Group VIII materials considered then shows through the experimental scatter. Data for further engineering materials are considered in these terms in Part II.

N-48161*

National Gas Turbine Establishment (Gt. Brit.) THE DISTRIBUTION OF IMPACTED PARTICLES OF VARIOUS SIZES ON THE BLADES OF A TURBINE CASCADE. D. L. Martlew. October 1956. 35p. diagrs., photo. NGTE Memo. M. 274. (Ask for N-48161*)

A turbine blade cascade was exposed to an airstream laden with droplets of paraffin wax. Particles in various size groups were counted and the variation of deposition rate with particle size and position on the blade surface estimated. The airflow in the cascade was calculated and the equations of motion of small particles moving initially with the air were integrated to give their paths. The relative deposition rates were calculated and compared with the measurements; good general agreement was obtained. The velocities and directions of impact with the blade were also estimated.

THE STRUCTURE AND LOW TEMPERATURE EMBRITTLEMENT OF TITANIUM-ALUMINIUM ALLOYS. K. S. Jepson, G. I. Lewis, and D. Clark. June 1956. 31p. diagrs., photos., tabs. RAE Tech. Note Met.241. (Ask for N-48173*)

In the titanium-aluminum system, solid solutions based on the hexagonal close packed allotropic form of titanium may contain up to 24 percent Al at room temperature; they are of interest because they have higher specific moduli than pure titanium. The limiting composition of commercially useful alloys is set at about 6 percent Al, by a progressive deterioration in working properties, with increasing aluminum content. In the present work alloys containing 5, 10, and 15 percent Al were made and all but the higher alloy were successfully fabricated to sheet. Attention was then primarily directed toward understanding the abnormal mechanical properties and microstructure found on examining the Ti 10-percent Al sheet. Specimens of rolled sheet given a recrystallization anneal high in the single-phase field and quenched were ductile, but if slower cooling was employed or if the quenched specimens were subsequently given a low temperature treatment they were rendered brittle. The microstructures of this supposedly single-phase alloy showed anomalous line markings similar to those on strained polished surfaces. X-ray diffraction, resistometric, and metallographic studies failed to show any connection between these two anomalous phenomena, nor has any evidence yet been found that the present phase diagram is wrong. It is suggested that anisotropic thermal contraction strains cause the microstructural abnormalities while the embrittlement is due to a rise in the critical stress for plastic deformation of the solid solution.

FLAME RADIATION IN AN INDUSTRIAL GAS TURBINE COMBUSTION CHAMBER. D. Reeves. October 1956. 65p. diagrs., tabs. NGTE Memo. M.285. (Ask for N-48177*)

Radiation properties of the flame were measured in a large combustion chamber; flame temperatures were deduced and the experimental results are presented in tables and graphically. The observations were made using four fuels, over a range of pressures, velocities, and fuel/air ratios, at four positions along the flame. Analysis of the results was approached by developing an expression for nonluminous emissivity in terms of the combustion variables and comparing the values so obtained with the observed total emissivities; the ratio of total emissivity to ideal nonluminous emissivity varied between 0.5 and 5. A general expression for total emissivity was thereby obtained but included a term, the luminous emission coefficient, which could not be correlated satisfactorily; its values are shown graphically for a range of combustion conditions. In the special case of gas oil flames, the coefficient of average luminous emission along a flame could be expressed empirically in terms of pressure and fuel/air ratio.

National Gas Turbine Establishment (Gt. Brit.)
REGULARITIES IN CREEP AND HOT FATIGUE DATA. PART II. K. F. A. Walles and A. Graham. December 1956. 144p. diagrs., tabs. NGTE R.190. (Ask for N-48178*)

A previously-given theory suggests that (for a single form of loading) strain ε is related to stress σ, time t, and temperature T by a sum of terms of the form $C_{\sigma\beta\phi k}$ where $\phi = t(T' - T)^{-A}$, that the constant A is the same for all terms and a range of materials, and that the ratios β/k take values from the sequence 2^n. In the present report, the theory is compared with 103 sets of published creep-rupture, creep-rate, and hot-fatigue data relating mainly to alloys of the Fe, Ni, Cr, Co, system of 44 different compositions. The results of all analyses are given in detail in the figures and tables. A statistical assessment of the extent of agreement of the theory with the data is given with reference to the number of free constants used.

Royal Aircraft Establishment (Gt. Brit.)
A NOTE ON TEST FACTORS. N. I. Bullen. September 1956. 18p. diagrs., tabs. RAE Structures 215. (Ask for N-48182*)

The calculation of test factors is reviewed. The distribution of the population from which the test sample is taken is assumed to be Gaussian. Three cases are discussed in which: (i) there is no prior knowledge of the mean or standard deviation, (ii) there is no prior knowledge of the mean but the standard deviation is a given fraction of the mean (that is, coefficient of variation known), and (iii) there is no prior knowledge of the mean but the standard deviation is known. In each case an estimate is made of the average proportion of items under strength which go into service as a result of the continued application of a given test factor. The distributions of the statistics used in the solution of cases (i) and (iii) can be found from published tables. The corresponding distributions for case (ii) for the appropriate ranges are given in this paper.

DEVELOPMENT OF PLANT, EQUIPMENT AND WELDING TECHNIQUES FOR FUSION WELDING THIN GAUGE AIRCRAFT MATERIALS WITH 'CRATER FREE' FINISHED WELDS TO AIRCRAFT STANDARDS. J. V. Thomas. October 1956. 25p. diagrs., photos., tabs. MOS S & T Memo. 6/56. (Ask for N-48184*)

Development work was started at Luton on stainless steel and Nimonic 75 in 20 S.W.G., 16 S.W.G., and 10 S.W.G. sheet materials. Arrangements had to be made to modify the existing prototype plant to accommodate the thinner gage materials, enabling sample welds to be produced of the length and diameters commonly used in aircraft industry. When fusion welding thin gage materials the current and voltage valves are usually small (20/70 amperes at 8/10 volts). To avoid even the slightest arc blow due to magnetic fields the clamps were made of non-magnetic materials.

National Gas Turbine Establishment (Gt. Brit.)
METHODS FOR REDUCTION OF HIGH TEMPERATURE DATA IN TERMS OF A THEORY OF DEFORMATION. K. F. A. Walles. December 1956. 41p. diagrs., tabs. NGTE Memo. M. 242. (Ask for N-48185*)

Procedures are described for analysis of creep curves, creep-rupture data, and hot-fatigue data in terms of the theory of NGTE Reports Nos. R. 94 and R. 137 which are summarized. Rapid graphical methods have been developed whose accuracy is fully adequate for data presently available. In addition to providing values of the constants in the theory they coordinate and summarize experimental data upon convenient graphs of stress versus a time-temperature variable from which values of e.g. strain for any combination of stress, time, and temperature within the experimental range may be immediately read by means of a sliding scale. The analysis of an extensive set of data takes only a short while and detailed study of data for a range of materials becomes practicable.

ON THE MINIMISATION AND NUMERICAL EVALUATION OF WAVE DRAG. E. Eminton. November 1955. 23p. diagrs., tabs. RAE Aero 2564. (Ask for N-48189*)

A Fourier analysis of the linearized theory expression for the zero-lift wave drag of a smooth, slender body in terms of its cross-sectional area distribution is used to derive the area distribution which minimizes the expression for given length, volume, nose area, base area, and n intermediate areas. Another minimal deduced from this by relaxing the restriction on volume is used to evolve a method for the numerical evaluation of the original expression. Two practical applications of these results are discussed. The first is in the design of wing-body combinations to have small drag rise at transonic speeds.

BRITISH REPORTS

The second is in the calculation of the wave drag of wing-body combinations at zero lift; an example is constructed to illustrate the method and to give an indication of its accuracy.

ANALYSIS OF A LOADED CANTILEVER PLATE BY FINITE DIFFERENCE METHODS. R. K. Livesley and P. C. Birchall. June 1956. 24p. RAE Tech. Note MS 26. (Ask for N-48190*)

The various difference patterns necessary for finite difference solution of rectangular plate problems, with various boundary conditions and under various transverse loads, are developed. The solution of one particular problem on DEUCE is also described.

N-48249*

Aeronautical Research Council (Gt. Brit.)
A CONSTRUCTIONAL METHOD FOR MINIMISING THE HAZARD OF CATASTROPHIC FAILURE IN A PRESSURE-CABIN. D. Williams. 1956. 13p. diagrs. ARC CP 286. (Ask for N-48249*)

A method is put forward for substantially reducing the chances of a local failure in the shell of a pressure cabin from developing into catastrophic failure of the cabin. The increased safety is achieved without weight penalty, and consists essentially in using closely spaced (10 inches or thereabouts) transverse flat bands, the material for which is obtained by reducing the sheet thickness normally available for the shell walls.

ON THE FORMATION OF SUPERCOOLED WATERDROPS AND ICE CRYSTALS IN THE ATMOSPHERE. (Über die Bildung der unterkühlten Wassertropfen und der Eiskristalle in der freien Atmosphäre). L. Krastanow. (1957). 30p. diagrs., tab. Translation from Meteorologische Zeitschrift, v. 57, no. 10, October 1940, p. 357-371. (Ask for N-51356*)

The formation of undercooled waterdrops and ice crystals under atmospheric conditions is treated quantitatively by using the Gibbs-Volmer theory of nucleation. Based on this theory, a method is developed which makes it possible to determine the rate of aggregation of the first condensation products at temperatures below 0° C and under atmospheric conditions, provided that the properties of condensation nuclei are known.

NACA RM A8J04

AERODYNAMIC STUDY OF A WING-FUSELAGE COMBINATION EMPLOYING A WING SWEPT BACK 63°. - CHARACTERISTICS AT A MACH NUMBER OF 1.53 INCLUDING EFFECT OF SMALL VARIATIONS OF SWEEP. Robert T. Madden. January 26, 1949. 71p. diagrs., photos., tabs. (NACA RM A8J04)

Measured values of lift, drag, and pitching moment at a Mach number of 1.53 and Reynolds numbers of 0.31, 0.62, and 0.84 million are presented for a wing-fuselage combination having a wing leading-edge sweep angle of 63°, an aspect ratio of 3.42, a taper ratio of 0.25, and an NACA 64A006 section in the stream direction. Data are also presented for sweep angles of 57.0°, 60.4°, 67.0°, and 69.9°. The experimentally determined characteristics were less favorable than indicated by the linear theory but the experimental and theoretical trends with sweep were in good agreement. Boundary-layer-flow tests showed that laminar boundary-layer separation was the primary cause of the differences between experiment and theory.

NACA RM A9C07

AERODYNAMIC STUDY OF A WING-FUSELAGE COMBINATION EMPLOYING A WING SWEPT BACK 63°. - INVESTIGATION AT A MACH NUMBER OF 1.53 TO DETERMINE THE EFFECTS OF CAMBERING AND TWISTING THE WING FOR UNIFORM LOAD AT A LIFT COEFFICIENT OF 0.25. Robert T. Madden. May 6, 1949. 33p. diagrs., photo., tabs. (NACA RM A9C07)

Measured values of lift, drag, and pitching moment at a Mach number of 1.53 are presented for wing-fuselage combinations having cambered and twisted wings with leading-edge sweep angles of 63°, 67°, and 70°. The results obtained with the 63° configuration when compared with those of an earlier investigation using a thicker uncambered, untwisted wing showed an increase in maximum lift-drag ratio from 7.2 to 8.3 at a Reynolds number of 0.84 million. The maximum lift-drag ratio increased with increased Reynolds number, a value of 9.0 being obtained at a Reynolds number of 0.95 million with the 67° configuration.

NACA RM A9C16

A COMPARISON OF THEORETICAL AND EXPERIMENTAL LOADING ON A 63° SWEPT-BACK WING AT SUPERSONIC SPEEDS. Victor I. Stevens and John W. Boyd. September 14, 1949. 21p. diagrs., photos. (NACA RM A9C16)

Results are presented for an investigation of the loading over a wing having 63° of sweepback, an aspect ratio of 3.5, and a taper ratio of 0.25 for Mach numbers from 1.15 to 1.7 and a Reynolds number of 4.5 million. The measured loading as a function of angle of attack is compared with that predicted by use of supersonic lifting-surface theory.

NACA RM A9C21

AERODYNAMIC STUDY OF A WING-FUSELAGE COMBINATION EMPLOYING A WING SWEPT BACK 63°. - EFFECTS OF SPLIT FLAPS, ELEVONS, AND LEADING-EDGE DEVICES AT LOW SPEED. Edward J. Hopkins. May 19, 1949. 46p. diagrs., photos. (NACA RM A9C21)

Measurements were made of the effects of a fuselage, split flaps, elevons, sharp leading edges, drooped-nose flaps, and extended-nose flaps on the lift, drag, and pitching-moment characteristics of a wing having the leading edge swept back 63° and having an aspect ratio of 3.5. Rolling moments produced by the elevons were also measured. Most of the tests were conducted at a Reynolds number of 4.2×10^6.

NACA RM A52C07

AERODYNAMIC CHARACTERISTICS OF TWO PLANE, UNSWEPT TAPERED WINGS OF ASPECT RATIO 3 AND 3-PERCENT THICKNESS FROM TESTS ON TRANSONIC BUMP. Horace F. Emerson and Bernard M. Gale. May 1952. 23p. diagrs., photo. (NACA RM A52C07)

An experimental investigation was conducted, using the transonic-bump technique, to determine the aerodynamic characteristics of two unswept tapered wing models, one having the NACA 0003-63 section and the other a 3-percent-thick circular-arc section, both in streamwise planes. The models had an aspect ratio of 3.0, taper ratio of 0.39, and the 60-percent-chord line unswept. Lift, drag, and pitching-moment coefficients are presented for a Mach number range from 0.60 to 1.10. The Reynolds number for the tests varied from 1.9 to 2.5 million.

NACA RM A52C10a

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - PLANE TRIANGULAR WING OF ASPECT RATIO 3 WITH AIR-TO-AIR MISSILE MODELS MOUNTED EXTERNALLY. Donald Conrard. June 1952. 28p. diagrs., photo. (NACA RM A52C10a)

This report presents the results of an investigation to ascertain the effects of externally mounted missile models on the lift, drag, and pitching moment of a

UNPUBLISHED PAPERS

wing-fuselage model having a triangular wing of aspect ratio 3 with an NACA 0003-63 section in streamwise planes. Results are shown for Mach numbers of 0.6, 0.9, 1.2, 1.4, and 1.7 at a constant Reynolds number of 4.8 million.

NACA RM A53A09

BUFFETING OF A VERTICAL TAIL ON AN INCLINED BODY AT SUPERSONIC MACH NUMBERS. Forrest E. Gowen. March 1953. 35p. diagrs., photos., tab. (NACA RM A53A09)

Time histories of the rolling moments on a body of revolution with a single vertical-tail fin were obtained in wind-tunnel tests. Data were taken at Mach numbers of 1.45, 1.98, and 2.90 in the range of Reynolds numbers (based on body diameter) from 0.2 million to 1.3 million. Models were tested with three longitudinal positions of the vertical fin and two nose shapes at angles of attack up to about 31°. At Mach numbers of 1.45 and 1.98, visual-flow studies and time histories of surface pressure were also made near the base of the bodies without the tail fin installed. Large aperiodic fluctuations in rolling moment and surface pressure were found to accompany the unsteadiness in the cross flow at large angles of attack.

NACA RM A54C30, by Rogallo, McCloud, and Yaggy

NACA RM A55C02

THE UNSTEADY NORMAL-FORCE CHARACTERISTICS OF SELECTED NACA PROFILES AT HIGH SUBSONIC MACH NUMBERS. Perry P. Polentz, William A. Page, and Lionel L. Levy, Jr. May 1955. 110p. diagrs., photos., tab. (NACA RM A55C02)

The magnitudes of normal-force fluctuations (unsteady normal force) are reported for 27 NACA profiles for angles of attack generally extending up to those corresponding to maximum lift, and Mach numbers from 0.5 to 0.9 at Reynolds numbers between 1 and 2 million. The variations of unsteady normal force with maximum thickness, camber, position of minimum pressure, and leading-edge radius are presented. Unsteady normal force was found to be a stationary random function of time; the principal defining variables, including the first probability density and the spectral density, are presented for some of the profiles at selected test points.

NACA RM A55C08

A CORRELATION OF AIRFOIL SECTION DATA WITH THE AERODYNAMIC LOADS MEASURED ON A 45° SWEPTBACK WING MODEL AT SUBSONIC MACH NUMBERS. Harold J. Walker and William C. Maillard. May 1955. 78p. diagrs., photo., tabs. (NACA RM A55C08)

A study is made at Mach numbers from 0.50 to 0.95 of the correlation between the experimental chordwise pressure distributions for various stations on a 45° sweptback-wing and body combination of aspect ratio 5.5 and those for the corresponding two-dimensional airfoil corrected for sweep. The applicability of airfoil section data, in conjunction with span-loading theory, for predicting the wing loading is also studied. The characteristics of the flow within and beyond the limiting conditions for good correlation are discussed.

NACA RM A55C23

A STUDY OF THE APPLICATION OF AIRFOIL SECTION DATA TO THE ESTIMATION OF THE HIGH SUBSONIC SPEED CHARACTERISTICS OF SWEPT WINGS. Lynn W. Hunton. June 1955. 37p. diagrs., tab. (NACA RM A55C23)

Estimates of the variation with Mach number of the aerodynamic characteristics of swept wings are made on the basis of airfoil section data combined with span-loading theory. The analysis deals with examinations of the lift, drag, and pitching moment of 26 wings and wing-body combinations ranging in sweep angle from 35° to 60° and for Mach numbers between 0.6 and 1.0.

NACA RM A55K14

EFFECT OF AREA-SUCTION-TYPE BOUNDARY-LAYER CONTROL ON THE LANDING-APPROACH CHARACTERISTICS OF A 35° SWEPT-WING FIGHTER. George E. Cooper and Robert C. Innis. February 1956. 35p. diagrs., photos., tabs. (NACA RM A55K14)

A flight evaluation of porous area-suction boundary-layer control applied to the wing flap of one 35° swept-wing fighter airplane and to the wing leading edge of another has been made. Pilots' opinions of the effects of these applications of porous area suction with respect to the landing-approach characteristics of the test airplanes are presented for 16 NACA, Navy, Air Force, and contractor pilots. Lift and thrust-required data are presented for each configuration and related to the pilots' opinions.

NACA RM A55K29

FLIGHT MEASUREMENTS OF THE LOW-SPEED CHARACTERISTICS OF A 35° SWEPT-WING AIRPLANE WITH AREA-SUCTION BOUNDARY-LAYER CONTROL ON THE FLAPS. Seth B. Anderson and Hervey C. Quigley. February 1956. 35p. diagrs., photos., tab. (NACA RM A55K29)

Tests were conducted to determine the flight characteristics of an F-86A airplane equipped with an area-suction boundary-layer-control system on the flaps. The effectiveness and suction requirements of the flap were determined and compared with wind-tunnel results. Take-off and landing performance data are presented as calculated from lift and drag measurements. Improvements in flap lift increment with suction are reflected in decreases in landing-approach speeds over the normal airplane.

UNPUBLISHED PAPERS

NACA RM A56G30

FLIGHT MEASUREMENTS OF THE LOW-SPEED CHARACTERISTICS OF A 35° SWEPT-WING AIRPLANE WITH BLOWING-TYPE BOUNDARY-LAYER CONTROL ON THE TRAILING-EDGE FLAPS. Seth B. Anderson, Hervey C. Quigley, and Robert C. Innis. October 1956. 52p. diagrs., photos., tabs. (NACA RM A56G30)

Tests were conducted to determine the flight characteristics of an F-86F airplane equipped with a blowing-type boundary-layer control system on the trailing-edge flaps. The effectiveness and flow requirements of the flap were determined and compared with other boundary-layer control applications. Take-off and landing performance data are presented as calculated from lift and drag measurements. Pilot evaluation of the blowing flap is included.

NACA RM E8L13

ALTITUDE-WIND-TUNNEL INVESTIGATION OF AN-F-58 FUEL IN EXPERIMENTAL VERSION OF J47 TURBOJET ENGINE. Carl L. Meyer. May 2, 1949. 16p. diagrs., tab. (NACA RM E8L13)

An altitude-wind-tunnel investigation of the performance of AN-F-58 and AN-F-32 fuels in an experimental turbojet engine was conducted over a range of simulated altitudes and flight Mach numbers. Combustion efficiencies obtained with AN-F-58 and AN-F-32 fuels were approximately equal. The minimum-speed altitude operational limit was essentially the same with either AN-F-58 or AN-F-32 fuel. Starting characteristics of the two fuels were approximately the same at low windmilling speeds. Visual observation showed no apparent differences in the carbon-deposition rates of AN-F-58 and AN-F-32 fuels.

NACA RM E9C11

EXPERIMENTAL INVESTIGATION OF LIQUID DIBORANE - LIQUID OXYGEN PROPELLANT COMBINATION IN 100-POUND-THRUST ROCKET ENGINE. William H. Rowe, Paul M. Ordin, and John M. Diehl. May 9, 1949. 25p. diagrs., photos., tab. (NACA RM E9C11)

Values of specific impulse were determined over a range of mixture ratios using a liquid diborane - liquid oxygen propellant combination in a 100-pound-thrust rocket engine. The maximum value of 274 pound-seconds per pound (correlated for heat rejection) occurred at a ratio of fuel weight to total propellant weight of 0.36. A few runs were made with an engine having a smaller characteristic length and also with an engine having another type of injection. A limited number of shock- and temperature-sensitivity determinations made with diborane produced no explosions nor detonations.

NACA RM E51A04

ALTITUDE OPERATION OF GAS-TURBINE ENGINE WITH VARIABLE-AREA FUEL-NOZZLE SYSTEM. H. Gold and S. Rosenzweig. April 2, 1951. 41p. diagrs., photos. (NACA RM E51A04)

The fuel consumption and combustion efficiency of a gas-turbine engine alternately equipped with variable- and with fixed-area fuel nozzles were investigated at altitudes up to 40,000 feet. At 40,000 feet, the engine when equipped with variable-area fuel nozzles operated with reduced fuel consumption and increased combustion efficiency. At lower altitudes, these gains, which are attributed to improved atomization, occurred at progressively lower engine-speed ranges. A correlation is presented between the percentage reduction in fuel consumption and the fuel consumption of the engine equipped with fixed-area fuel nozzles. This percentage reduction is a function of fuel-flow rate through the nozzles.

NACA RM E51H13

AERODYNAMICS OF SLENDER BODIES AT MACH NUMBER OF 3.12 AND REYNOLDS NUMBERS FROM 2×10^6 TO 15×10^6. I - BODY OF REVOLUTION WITH NEAR-PARABOLIC FOREBODY AND CYLINDRICAL AFTERBODY. John R. Jack and Warren C. Burgess. November 1951. 47p. diagrs., photos. (NACA RM E51H13)

An experimental investigation of the aerodynamic characteristics of a slender, square-based body of revolution was conducted at a Mach number of 3.12 for angles of attack from 0° to 10° and for Reynolds numbers from 2×10^6 to 15×10^6. Boundary-layer measurements at zero angle of attack are compared with several compressible flow formulations for predicting boundary-layer characteristics. Comparison of experimental pressure and force values with theoretical values showed good agreement for low angles of attack. The measured mean skin-friction coefficients agreed well with those predicted by Mangler's transformation for laminar flow over cones.

UNPUBLISHED PAPERS

NACA RM E51H30

PRELIMINARY RESULTS OF TURBOJET-ENGINE ALTITUDE-STARTING INVESTIGATION. H. D. Wilsted and J. C. Armstrong. November 1951. 25p. diagrs. (NACA RM E51H30)

A spark energy of 2.13 joules per spark at 1 spark per second produced ignition to an altitude of 50,000 feet at a flight Mach number of 0.6. The minimum power requirements for ignition were obtained from a combination of low spark repetition rates and high spark energy. The altitude-ignition limit was also increased by increasing spark-gap immersion, fuel temperature, inlet-air temperature, and fuel volatility, and by decreasing flight Mach number. The maximum altitude at which flame propagation was accomplished from combustors with spark plugs to combustors without spark plugs was increased about 5000 feet by increasing fuel volatility.

NACA RM E52H04

SOME DYNAMIC CHARACTERISTICS OF A TURBOJET ENGINE FOR LARGE ACCELERATIONS. Herbert Heppler, David Novik, and Marcel Dandois. August 1952. 20p. diagrs., photos. (NACA RM E52H04)

Dynamics of an axial-flow turbojet engine with a fixed area exhaust nozzle were obtained from successively larger transients including successful accelerations through surge. In the low-speed range, appreciable changes in thrust were obtainable only as a result of changes in speed. Beyond an optimum step increase in fuel flow at each engine speed, further increases in the size of the fuel step did not result in further increases in acceleration and thrust, and a curve of maximum acceleration was obtained. Maximum acceleration and thrust appeared obtainable through the use of a proposed fuel schedule that required only small initial steps in fuel flow.

NACA RM E53J15

A METHOD OF MEASURING JET THRUST OF TURBOJET ENGINES IN FLIGHT INSTALLATIONS. Joseph N. Sivo and David B. Fenn. January 1954. 19p. diagrs., photo. (NACA RM E53J15)

Measurement of the jet thrust of a turbojet engine in flight becomes more difficult as the number and complexity of the engine components increase. It is desirable, therefore, that a general correlation of jet thrust be developed which is applicable to a simple direct reading thrustmeter. In view of this need a correlation is presented which is independent of flight conditions and applicable to both nonafterburning and afterburning engines equipped with nonejector type fixed- and variable-area convergent exhaust nozzles. The general equation used in this correlation was derived from the theoretical jet-thrust equation for a choked convergent nozzle. The data used to verify the correlation were obtained over a range of altitudes from 10,000 to 54,000 feet and a range of flight Mach numbers from 0.4 to 1.1. A thrustmeter based on this equation was installed on an afterburning turbojet engine equipped with a fixed-area convergent exhaust nozzle. The results indicated that a meter based on this correlation would be applicable to a flight installation and that probable error in thrust measurement would be approximately ±1.5 percent provided the exhaust-nozzle thrust coefficient is known.

NACA RM E54C11

EXPERIMENTAL INVESTIGATION OF THE EFFECT OF A SHROUDED ROTOR ON THE PERFORMANCE OF A CONSERVATIVELY DESIGNED TURBINE. Cavour H. Hauser and Henry W. Plohr. May 1954. 14p. diagrs., photo. (NACA RM E54C11)

In order to determine the effect of shrouding the rotor blades of a particular turbine design on the overall turbine performance, a conservatively designed experimental cold-air turbine was investigated both with and without a shroud band on the rotor blades. The tip of the rotor blade was oriented toward the tangential direction so that the adverse effect of blade-tip scraping would not be appreciable. It was found that the addition of a shroud to the turbine rotor blades had only a slight effect and did not improve the turbine performance. The efficiency for the unshrouded-rotor configuration was about one point higher than for the shrouded rotor.

NACA RM E54C18

EXPERIMENTAL INVESTIGATION OF EFFECT OF HIGH-ASPECT-RATIO ROTOR BLADES ON PERFORMANCE OF CONSERVATIVELY DESIGNED TURBINE. Cavour H. Hauser and William J. Nusbaum. May 1954. 13p. diagrs., photo. (NACA RM E54C18)

A considerable weight reduction in the turbine wheel of an aircraft gas turbine is attained through the use of high-aspect-ratio rotor blading. An experimental investigation was made to compare the performance of a turbine of conservative aerodynamic design having shrouded rotor blades with an aspect ratio of 4.48 with that obtained from both a shrouded and an unshrouded rotor design with aspect ratio of 2.24. The use of high-aspect-ratio rotor blades had a negligible effect on the turbine efficiency.

NACA RM E55C22

INJECTION PRINCIPLES FROM COMBUSTION STUDIES IN A 200-POUND-THRUST ROCKET ENGINE USING LIQUID OXYGEN AND HEPTANE. M. F. Heidmann and C. M. Auble. June 1955. 55p. diagrs., photos., tabs. (NACA RM E55C22)

Ten injectors were tested in a 200-pound-thrust rocket engine with liquid oxygen and heptane. The injectors were designed to evaluate the relative importance of atomizing and mixing the propellants. Characteristic velocity, chamber gas velocity, and combustion photographs were compared. The results showed that atomizing the fuel controlled the combustion rate to a much larger extent than atomizing the oxygen. Induced mixing, however, completed combustion in the smallest volume. For stable, high-efficiency combustion and smooth engine starts, mixing after atomization was most promising.

NACA RM E55D28

CORRELATION OF TURBOJET COMBUSTOR CARBON FORMATION WITH SMOKE-VOLATILITY INDEX, SMOKE POINT, AND NACA K FACTOR. Edmund R. Jonash, Helmut F. Butze, and William P. Cook. June 1955. 28p. diagrs., photos., tabs. (NACA RM E55D28)

Carbon-forming characteristics of MIL-F-5624 grades JP-3 and JP-4 jet fuels were determined in a single-tubular combustor. While three empirical fuel factors satisfactorily correlated combustor deposit and exhauxt-gas smoke data obtained at one operating condition, none was satisfacotry at a higher pressure and temperature. Further, only deposit data obtained at the first condition correlated with full-scale engine results obtained with the same fuels.

NACA RM E55J31

EFFECT OF FUEL ADDITIVES ON CARBON DEPOSITION IN A J33 SINGLE COMBUSTOR. IV - NINE OXYGEN-BEARING COMPOUNDS. Edmund R. Jonash, William P. Cook, and Jerrold D. Wear. February 1956. 12p. diagrs., photos., tabs. (NACA RM E55J31)

The effectiveness of nine oxygen-bearing additives in reducing carbon formation of No. 2 furnace oil was studied in a single turbojet combustor. Among the additives tested only four, three alkyl nitrates, and diethyl ether, reduced carbon deposits significantly; the largest reduction, 30 percent, was obtained with a 1.0 percent by weight concentration of iso-octyl nitrate. None of the additives had a significant effect on exhaust-gas-smoke concentration.

NACA RM L8A05a

RESULTS OBTAINED DURING ACCELERATED TRANSONIC TESTS OF THE BELL XS-1 AIRPLANE IN FLIGHTS TO A MACH NUMBER OF 0.92. Hubert M. Drake, Milton D. McLaughlin, and Harold R. Goodman. April 19, 1948. 22p. diagrs., tab. (NACA RM L8A05a)

Results are presented of tests up to a Mach number of 0.92 at altitudes around 30,000 feet. The data obtained show that the airplane can be flown to this Mach number above 30,000 feet. Longitudinal trim changes have been experienced but the forces involved have been small. The elevator effectiveness decreased about one-half with increase of Mach number from 0.70 to 0.87. Buffeting has been experienced in level flight but it has been mild and the associated tail loads have been small. No aileron buzz or other flutter phenomena have been noted.

NACA RM L8A23a

RESULTS OF PRELIMINARY FLIGHT TESTS OF THE XS-1 AIRPLANE (8-PERCENT WING) TO A MACH NUMBER OF 1.25. W. C. Williams and De E. Beeler. April 6, 1948. 14p. diagrs. (NACA RM L8A23a)

Presents results of the U.S. Air Forces' accelerated transonic flight tests of the XS-1 No. 1 airplane for the Mach number range from 0.70 to 1.25 at altitudes from 30,000 to 49,000 feet. Data are included on horizontal-tail loads and buffeting, longitudinal trim changes, elevator effectiveness and control forces, and lateral trim characteristics.

NACA RM L8C23a

RESULTS OBTAINED DURING A DIVE RECOVERY OF THE BELL XS-1 AIRPLANE TO HIGH LIFT COEFFICIENTS AT A MACH NUMBER GREATER THAN 1.0. Milton D. McLaughlin and Dorothy C. Clift. April 6, 1948. 6p. diagrs. (NACA RM L8C23a)

Measured quantities are presented which were obtained on the Bell XS-1 airplane with an 8-percent-thick wing and a 6-percent-thick horizontal tail during a dive recovery at a Mach number greater than 1.0. The data obtained show that it is possible to obtain fairly high load factors with the airplane at Mach numbers greater than 1.0 if the stabilizer is used for longitudinal control. Lift coefficients approaching low-speed maximum-lift values have been obtained at a Mach number of 1.1 with no indication that these values are the maximum obtainable for the airplane. At the Mach number and lift coefficient reported, there was little or no buffeting.

UNPUBLISHED PAPERS

NACA RM L51A12

FREE-FLIGHT-TUNNEL INVESTIGATION OF THE DYNAMIC LATERAL STABILITY AND CONTROL CHARACTERISTICS OF A TIP-TO-TIP BOMBER-FIGHTER COUPLED AIRPLANE CONFIGURATION. Charles V. Bennett and Robert B. Cadman. April 4, 1951. 16p. diagrs., tab. (NACA RM L51A12)

The results are presented of an experimental investigation conducted in the Langley free-flight tunnel to determine the dynamic stability and control characteristics of a coupled airplane configuration consisting of a simplified fighter model attached to each wing tip of a simplified bomber model. The fighter models could be attached either rigidly, or with freedom in roll, freedom in roll and pitch, or freedom in roll, pitch, and yaw with respect to the bombers.

NACA RM L52C26

FLIGHT INVESTIGATION FROM MACH NUMBER 0.8 TO MACH NUMBER 2.0 TO DETERMINE SOME EFFECTS OF WING-TO-TAIL DISTANCE ON THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 60° DELTA-WING-CANARD MISSILE. Clarence A. Brown, Jr., and Reginald R. Lundstrom. June 1952. 42p. diagrs., photos. (NACA RM L52C26)

A flight test was conducted on a 60° delta wing and canard missile configuration with a long fuselage. Stability derivatives, control hinge moment, and drag characteristics are presented throughout a Mach number range of 0.80 to 2.0. Comparison is made with data from a similar model having a shorter fuselage.

NACA RM L52E05a

FLOW SEPARATION FROM RODS AHEAD OF BLUNT NOSES AT MACH NUMBER 2.72. Jim J. Jones. July 1952. 18p. diagrs., photos. (NACA RM L52E05a)

An experimental investigation has been made of the flow separation from slender rods mounted to extend forward along the axes of symmetry of blunt-nosed bodies. The mechanism of the separation and its governing criteria are discussed. Drag data at a Mach number of 2.72 for various rod lengths and nose radii at an angle of attack of 0° are presented.

NACA RM L54C02

THREE-DEGREE-OF-FREEDOM EVALUATION OF THE LONGITUDINAL TRANSFER FUNCTIONS OF A SUPERSONIC CANARD MISSILE CONFIGURATION INCLUDING CHANGES IN FORWARD SPEED. Ernest C. Seaberg. April 1954. 29p. diagrs., photo., tabs. (NACA RM L54C02)

The three-degree-of-freedom longitudinal equations of motion including changes in forward speed are applied to a supersonic canard missile of the boost-glide type to determine the longitudinal transfer functions. These transfer functions are presented in the form of frequency-response plots for several flight conditions. For a constant Mach number, the frequency response is shown to vary with angle of attack, mainly in the region of low-frequency airframe operation. A comparison of the frequency responses thus obtained with those in which the forward speed change is neglected also shows significant variation in the low-frequency region. The additional derivatives necessary for this study (namely C_{D_α}, C_{D_u}, C_{L_u}, and C_{m_u}) were obtained from a reevaluation of existing flight data and are evaluated for a Mach number range from transonic to approximately 1.8.

NACA RM L54C08

MEASUREMENTS AND PREDICTIONS OF FLOW CONDITIONS ON A TWO-DIMENSIONAL BASE SEPARATING A MACH NUMBER 3.36 JET AND A MACH NUMBER 1.55 OUTER STREAM. Donald E. Coletti. May 1954. 56p. diagrs., photos. (NACA RM L54C08)

Results are presented of an investigation made in a mixing-zone apparatus of the effects of jet flow on two-dimensional base pressure, including a prediction of the base pressure. The development of supersonic-channel flow about a two-dimensional base, with and without splitter plates of different thicknesses was also investigated. The Mach number of the outer stream was 1.55 and the center-jet Mach number was 3.36. Pressure measurements and observations of the flow are presented.

NACA RM L54C10

ROCKET-POWERED-MODEL INVESTIGATION OF THE HINGE-MOMENT AND NORMAL-FORCE CHARACTERISTICS OF A HALF-DIAMOND TIP CONTROL ON A 60° SWEPTBACK DIAMOND WING BETWEEN MACH NUMBERS OF 0.5 AND 1.3. James D. Church. April 1954. 30p. diagrs., photos., tab. (NACA RM L54C10)

Control-force and hinge-moment characteristics were obtained from a free-flight investigation of a rocket-powered research model equipped with 60° sweptback diamond wings having 30° sweptforward trailing edges featuring half-diamond tip controls. Data were obtained for control deflections up to ±13° and for angles of attack from ±3° to ±14° between Mach numbers of 0.5 and 1.3. Comparisons are made with other rocket-powered-model test results.

NACA RM L54C26

WIND-TUNNEL INVESTIGATION OF EFFECT OF SWEEP ON ROLLING DERIVATIVES AT ANGLES OF ATTACK UP TO 13° AND AT HIGH SUBSONIC MACH NUMBERS, INCLUDING A SEMIEMPIRICAL METHOD OF ESTIMATING THE ROLLING DERIVATIVES. James W. Wiggins. April 1954. 47p. diagrs., tab. (NACA RM L54C26)

Results are presented of an investigation to determine the rolling derivatives for swept-wing—body configurations. The wing had sweep angles at the quarter-chord line of 3.6°, 32.6°, 45°, and 60°, an aspect ratio of 4, a taper ratio of 0.6, and an NACA

UNPUBLISHED PAPERS

65A006 airfoil section parallel to the free stream. The angle-of-attack range was from 0° to 13° and the Mach number range was from 0.50 to 0.95, corresponding to a Reynolds number range from 1.8×10^{6} to 3.0×10^{6}. Tests at selected angles of attack were repeated for the 45° swept wing with fences located at the 65-percent-semispan station. Included is a semiempirical method for estimating the rolling derivatives.

NACA RM L55G05

A THEORETICAL ANALYSIS OF THE EFFECT OF ENGINE ANGULAR MOMENTUM ON LONGITUDINAL AND DIRECTIONAL STABILITY IN STEADY ROLLING MANEUVERS. Ordway B. Gates, Jr., and C. H. Woodling. October 1955. 20p. diagrs., tab. (NACA RM L55G05)

The effect of engine momentum on the longitudinal and directional stability of aircraft in steady rolling maneuvers has been investigated. The results presented indicate that the gyroscopic moments produced on the aircraft by the rotating engine in rolling maneuvers can have an appreciable effect on the range of rolling velocities for which longitudinal or directional instability might occur.

NACA RM L56F04

A SIMPLIFIED METHOD FOR APPROXIMATING THE TRANSIENT MOTION IN ANGLES OF ATTACK AND SIDESLIP DURING A CONSTANT ROLLING MANEUVER. Leonard Sternfield. August 1956. 38p. diagrs., tabs. (NACA RM L56F04)

A simplified method for approximating the transient motion in angles of attack and sideslip during a constant rolling maneuver is presented. From the expressions presented in the paper, the pertinent modes of motion as well as the modal coefficient corresponding to each mode can be determined. Calculations made with and without the derivatives $C_{Y_{\beta}}$ (side force due to sideslip) and $C_{L_{\alpha}}$ (lift-curve slope) indicate that although these derivatives increase the total damping of the system, they do not markedly affect the transient motion.

NACA Rept. 1268

THEORETICAL CALCULATIONS OF THE PRESSURES, FORCES, AND MOMENTS AT SUPERSONIC SPEEDS DUE TO VARIOUS LATERAL MOTIONS ACTING ON THIN ISOLATED VERTICAL TAILS. Kenneth Margolis and Percy J. Bobbitt. 1956. ii, 44p. diagrs., tabs. (NACA Rept. 1268. Supersedes TN 3373; TN 3240)

Velocity potentials, pressure distributions, and stability derivatives have been derived by use of supersonic linearized theory for families of thin isolated vertical tails performing steady rolling, steady yawing, constant sideslip, and constant-lateral-acceleration motions. Vertical-tail families (half-delta and rectangular plan forms) are considered for a broad Mach number range. Also considered are the vertical tail with arbitrary sweepback and taper ratio at Mach numbers for which both the leading edge and trailing edge of the tail are supersonic and the triangular vertical tail with a subsonic leading edge and a supersonic trailing edge. End-plate effects for several of the derivatives are included.

NACA Rept. 1270

REVIEW OF EXPERIMENTAL INVESTIGATIONS OF LIQUID-METAL HEAT TRANSFER. Bernard Lubarsky and Samuel J. Kaufman. 1956. ii, 33p. diagrs., tab. (NACA Rept. 1270. Supersedes TN 3336)

Experimental data of various investigators of liquid-metal heat-transfer characteristics were reevaluated using as consistent assumptions and methods as possible and then compared with each other and with theoretical results. The reevaluated data for both local fully developed and average Nusselt numbers in the turbulent flow region were found still to have considerable spread, with the bulk of the data being lower than predicted by existing analysis. An equation based on empirical grounds which represents most of the fully developed heat-transfer data is $Nu = 0.625\ Pe^{0.4}$ where Nu represents the Nusselt number and Pe the Peclet number. The theoretical prediction of the heat transfer in the entrance region was found to give lower values, in most cases, than those found in the experimental work.

NACA Rept. 1272

A REEVALUATION OF DATA ON ATMOSPHERIC TURBULENCE AND AIRPLANE GUST LOADS FOR APPLICATION IN SPECTRAL CALCULATIONS. Harry Press, May T. Meadows, and Ivan Hadlock. 1956. ii, 29p. diagrs., tabs. (NACA Rept. 1272. Supersedes TN 3362; TN 3540)

The available information on the spectrum of atmospheric turbulence is first briefly reviewed. On the basis of these results, methods are developed for the conversion of available gust statistics normally given in terms of counts of gusts or acceleration peaks into a form appropriate for use in spectral calculations. The fundamental quantity for this purpose appears to be the probability distribution of the root-mean-square gust velocity. Estimates of this distribution are derived from data for a number of load histories of transport operations; also, estimates of the variation of this distribution with altitude and weather condition are derived from available data and the method of applying these results to the calculation of airplane gust-response histories in operations is also outlined.

NACA Rept. 1275

THE PROPER COMBINATION OF LIFT LOADINGS FOR LEAST DRAG ON A SUPERSONIC WING. Frederick C. Grant. 1956. ii, 9p. diagrs., tab. (NACA Rept. 1275. Supersedes TN 3533)

Lagrange's method of undetermined multipliers is applied to the problem of properly combining lift loadings for the least drag at a given lift on supersonic wings. The interference drag between the optimum loading and any loading at the same lift coefficient is found to be constant on a given plan form. This is an integral form of a criterion established by Robert T. Jones for optimum loadings. The best combination of four loadings on a delta wing with subsonic leading edges is calculated as a numerical example.

NACA Rept. 1276

WIND-TUNNEL AND FLIGHT INVESTIGATIONS OF THE USE OF LEADING-EDGE AREA SUCTION FOR THE PURPOSE OF INCREASING THE MAXIMUM LIFT COEFFICIENT OF A 35° SWEPT-WING AIRPLANE. Curt A. Holzhauser and Richard S. Bray. 1956. ii, 24p. diagrs., photos., tabs. (NACA Rept. 1276. Supersedes RM A52G17; RM A55C07)

Wind tunnel and flight tests were made to evaluate the lift characteristics and suction requirements of a 35° swept-wing airplane with a leading edge area-suction boundary-layer-control installation. Large gains in maximum lift coefficients were obtained, and the resulting stalling characteristics of the airplane were tolerable to good. The porous leading edge had no marked detrimental effect on the operational performance of the airplane.

NACA Rept. 1281

FLIGHT DETERMINATION OF DRAG OF NORMAL-SHOCK NOSE INLETS WITH VARIOUS COWLING PROFILES AT MACH NUMBERS FROM 0.9 TO 1.5. R. I. Sears, C. F. Merlet, and L. W. Putland. 1956. ii, 19p. diagrs., photos., tabs. (NACA Rept. 1281. Supersedes RM L53I25a)

External-drag data are presented for normal-shock nose inlets with NACA 1-series, parabolic, and conic cowling profiles. The tests were made at an angle of attack of 0° by using rocket-propelled models in free flight at Mach numbers from 0.9 to 1.5. The Reynolds number based on body maximum diameter varied from 2.5×10^6 to 5.5×10^6. At maximum flow rate, the inlet models had about the same external drag at a Mach number of approximately 1.1, but at higher Mach numbers the sharp-lip conic cowling had the least drag. Blunting or beveling the lip of the conic cowling while keeping the fineness ratio constant resulted in drag coefficients slightly higher than for the sharp-lip conic cowling at maximum flow rate. At a mass-flow ratio of about 0.8, the conic cowlings with sharp, blunt, or beveled lips and the parabolic cowling all gave about the same drag.

NACA RM L57A11

PRELIMINARY MEASUREMENTS OF ATMOSPHERIC TURBULENCE AT HIGH ALTITUDE AS DETERMINED FROM ACCELERATION MEASUREMENTS ON LOCKHEED U-2 AIRPLANE. Thomas L. Coleman and Jack Funk. March 1957. 14p. diagrs., tab. (NACA RM L57A11)

An analysis of turbulence data obtained from VGH records covering approximately 22,000 flight miles taken on Lockheed U-2 airplanes during research flights up to 55,000 feet over England and Western Europe is presented. Substantial reductions in the number and intensity of gusts with increasing altitude are indicated. The results on the variation of the amount and intensity of turbulence with altitude are compared with turbulence data previously obtained from airplane- and balloon-borne instruments over the United States.

NACA TM 1405

STEADY NUCLEAR COMBUSTION IN ROCKETS. (Stationäre Kernverbrennung in Raketen). E. Sänger. April 1957. 39p. diagrs., tab. (NACA TM 1405. Translation from Astronautica Acta, v.1, pt.2, 1955, p.61-88)

Astrophysical theory is applied to study possibilities for thermonuclear reactions to be used as an energy source for the propulsion of atomic rockets, photon rockets, turbojets, and ram jets. Results indicate maximum heat production at 10^8 °K for the hydrogen isotopes. For chamber pressures of 100 atm the energy release 10^4 kcal/(cu m)(sec) is comparable to that of the chemical fuels. The effect of burnup time and of the degree of complete ionization on the balance between energy release and energy radiated is determined.

NACA TM 1430

THE EFFECT OF SOLID ADMIXTURES ON THE VELOCITY OF MOTION OF A FREE DUSTY AIR JET. (K Voprosu o Vliyanii Tverdykh Primecei na Skorost' Dvizheniya Svobodnoi Pylevozdushnoi Strui). A. P. Chernov. April 1957. 7p. diagr. (NACA TM 1430. Translation from Zhurnal Tekhnicheskoi Fiziki, v.26, no.5, 1956, p.1060-1063)

The presence of solid pulverized particles suspended in air in concentrations of up to 1 kg particles/1 kg air and velocities less than 30 m/sec has no significant effect on the aerodynamics of air jet. For velocities greater than 30 m/sec and concentrations different than 1 the effect can be calculated.

NACA TN 3780

INCOMPRESSIBLE FLUTTER CHARACTERISTICS OF REPRESENTATIVE AIRCRAFT WINGS. C. H. Wilts, California Institute of Technology. April 1957. 121p. diagrs., tabs. (NACA TN 3780)

The present report gives the results of a detailed study of the flutter characteristics of four representative aircraft wings. This study was made using the electric analog computer at the California Institute of Technology. During the course of this investigation, eight important parameters of each wing were varied and, in addition, the effects of mass, inertia, pitching spring, and location of a concentrated mass were investigated for all four wings and several sweepback angles.

NACA TN 3824

EFFECT OF AN INTERFACE ON TRANSIENT TEMPERATURE DISTRIBUTION IN COMPOSITE AIRCRAFT JOINTS. Martin E. Barzelay and George F. Holloway, Syracuse University. April 1957. 51p. diagrs., photo., tabs. (NACA TN 3824)

Geometrically related structural joints representing typical skin-stringer cross sections were tested under radiant heating to simulate the effects of aerodynamic heating. Temperature histories for 15 2024-T fabricated specimens and an equal number of integral control specimens were recorded for two

CURRENT NACA RESEARCH REPORTS

different constant heat inputs, ranging from approximately 5 to 40 Btu/(sq ft)(sec). Interface conductance values were computed for each of the 15 fabricated specimens. A maximum temperature rise of 450° F was attained in the specimens in 8 to 40 seconds of heating. There was no restraint or external loading applied.

NACA TN 3826

INVESTIGATION OF A NONLINEAR CONTROL SYSTEM. I. Flügge-Lotz and C. F. Taylor, Stanford University. April 1957. 92p. diagrs., tabs. (NACA TN 3826)

A discontinuous variation of coefficients of the differential equation describing the linear control system before nonlinear elements are added is studied in detail. The nonlinear feedback is applied to a second-order system. Simulation techniques are used to study performance of the nonlinear control system and to compare it with the linear system for a wide variety of inputs. A preliminary extension of this type of system to higher order systems is presented.

NACA TN 3845

INVESTIGATION OF THE EFFECTS OF LEADING-EDGE CHORD-EXTENSIONS AND FENCES IN COMBINATION WITH LEADING-EDGE FLAPS ON THE AERODYNAMIC CHARACTERISTICS AT MACH NUMBERS FROM 0.40 TO 0.93 OF A 45° SWEPT-BACK WING OF ASPECT RATIO 4. Kenneth P. Spreemann and William J. Alford, Jr. April 1957. 45p. diagrs., photo., tabs. (NACA TN 3845. Supersedes RM L53A09a)

An investigation was conducted in the Langley high-speed 7- by 10-foot tunnel over a Mach number range of 0.40 to 0.93 to determine the effects of a number of wing leading-edge modifications and fences on the aerodynamic characteristics in pitch of a wing-fuselage combination with the wing quarter-chord line swept back 45°, aspect ratio 4.0, taper ratio 0.3, and an NACA 65A006 airfoil section. Lift, drag, and pitching moment were obtained for all configurations over an angle-of-attack range of about -2° to 24°.

NACA TN 3908

HYDRODYNAMIC CHARACTERISTICS OVER A RANGE OF SPEEDS UP TO 80 FEET PER SECOND OF A RECTANGULAR MODIFIED FLAT PLATE HAVING AN ASPECT RATIO OF 0.25 AND OPERATING AT SEVERAL DEPTHS OF SUBMERSION. Victor L. Vaughan, Jr., and John A. Ramsen. April 1957. 23p. diagrs. (NACA TN 3908)

Results of an investigation of the hydrodynamic characteristics over an extended speed range of a rectangular modified flat plate having an aspect ratio of 0.25 and operating at several depths of submersion are presented. Comparisons between these data and data over a lower speed range on a similar aspect-ratio-0.25 flat plate but having one-half the thickness are presented. These comparisons show no significant differences at the low speeds. At high speeds and high angles of attack, where extensive cavitation was present, the lift coefficients were lower than would have been indicated by the results of the previous investigations and the present investigation at the lower angles of attack. A brief discussion and comparison of ventilation are presented which shows two types of planing bubble formation and the effect of increasing the thickness of the model on the ventilation boundary.

NACA TN 3910

THE RESPONSE OF AN AIRPLANE TO RANDOM ATMOSPHERIC DISTURBANCES. Franklin W. Diederich, California Institute of Technology. April 1957. ii, 95p. diagrs., tab. (NACA TN 3910)

The statistical approach to the gust-load problem which consists in considering flight through turbulent air to be a stationary random process is extended by including the effect of lateral variation of the instantaneous gust intensity on the aerodynamic forces. The forces obtained in this manner are used in dynamic analyses of rigid and flexible airplanes free to move vertically, in pitch, and in roll. The effect of the interaction of longitudinal, vertical, and lateral gusts on the wing stresses is also considered.

NACA TN 3953

A LIMITED CORRELATION OF ATMOSPHERIC SOUNDING DATA AND TURBULENCE EXPERIENCED BY ROCKET-POWERED MODELS. Homer P. Mason and William N. Gardner. April 1957. 51p. diagrs., tab. (NACA TN 3953)

Atmospheric turbulence as experienced by rocket-powered models and temperature lapse-rate data obtained from rawinsonde soundings have been analyzed and compared in 38 cases by using an assumed lapse-rate stability boundary. A limited correlation has been obtained which shows that a large percentage of turbulent conditions can be avoided by making rocket-model flight tests only during marginal or stable lapse-rate conditions.

NACA TN 3955

A COLLECTION OF DATA FOR ZERO-LIFT DAMPING IN ROLL OF WING-BODY COMBINATIONS AS DETERMINED WITH ROCKET-POWERED MODELS EQUIPPED WITH ROLL-TORQUE NOZZLES. David G. Stone. April 1957. 23p. diagrs., tab. (NACA TN 3955. Supersedes RM L53E26)

Zero-lift damping-in-roll data have been collected from experimentally determined results through high subsonic, transonic, and low supersonic speeds by a torque-nozzle forced-roll technique utilizing rocket-propelled models. These collections of data show the effects of wing plan form and airfoil section and, qualitatively, the effects of wing aeroelasticity. These collections also show all wings tested to have damping in roll in this speed range at 0° angle of attack.

CURRENT NACA RESEARCH REPORTS

NACA TN 3958

ANALYSIS OF STATIC AEROELASTIC BEHAVIOR OF LOW-ASPECT-RATIO RECTANGULAR WINGS. John M. Hedgepeth and Paul G. Waner, Jr. April 1957. 21p. diagrs. (NACA TN 3958)

Slender-body theory is used in conjunction with plate theory to analyze the static aeroelastic-divergence behavior of low-aspect-ratio rectangular wings of constant thickness when chordwise deformations are considered. In the analysis, the spanwise variation of the deflection is restricted to a parabola but the chordwise variation is allowed complete freedom. Results show the variation of the divergence speed and mode shape with the aspect ratio. Comparisons are made with results obtained by using approximate (linear, parabolic, and cubic) chordwise deflection shapes.

NACA TN 3960

EXPECTED NUMBER OF MAXIMA AND MINIMA OF A STATIONARY RANDOM PROCESS WITH NON-GAUSSIAN FREQUENCY DISTRIBUTION. Franklin W. Diederich. April 1957. 21p. tabs. (NACA TN 3960)

A method is presented for correcting the known results for the expected number of maxima and minima of a random process with Gaussian frequency distribution for cases in which the joint frequency-distribution function of the process and its first two derivatives is non-Gaussian. This correction is based on the statistical moments of the process and its first two derivatives and involves certain given functions.

NACA TN 3974

FULL-SCALE INVESTIGATION OF SEVERAL JET-ENGINE NOISE-REDUCTION NOZZLES. Willard D. Coles and Edmund E. Callaghan. April 1957. 45p. diagrs., photos., tabs. (NACA TN 3974)

A number of nozzles which use the mixing interference of adjacent jets for noise suppression were investigated. Reductions in sound power of nearly 70 percent (5 db) with thrust losses of 1 percent were achieved. A method of calculating the limiting frequency affected by this type of suppression nozzle, that is, multiple-slot nozzles, is presented. Data are shown which indicate that further large reductions in sound power are not likely with mixing-interference nozzles.

NACA TN 3976

RUPTURE STRENGTH OF SEVERAL NICKEL-BASE ALLOYS IN SHEET FORM. James H. Dance and Francis J. Clauss. April 1957. 24p. diagrs., photos., tabs. (NACA TN 3976)

The 100-hour rupture strengths of Inconel X, Inconel 700, Incoloy 901, Refractaloy 26, and R-235 at 1200° and 1350° F in both the annealed and heat-treated conditions were determined. Inconel 700 had the highest rupture strength at both temperatures; Incoloy 901 was second strongest at 1200° F, and R-235 second strongest at 1350° F. With the exception of Incoloy 901, ductility was low. Photomicrographs show that fractures are through the grain boundaries. Results are compared with published data for other sheet alloys and bar stock.

NACA TN 3977

FURTHER EXPERIMENTS ON THE STABILITY OF LAMINAR AND TURBULENT HYDROGEN-AIR FLAMES AT REDUCED PRESSURES. Burton Fine. April 1957. 31p. diagrs., tabs. (NACA TN 3977)

Stability limits for laminar and turbulent hydrogen-air burner flames were measured as a function of pressure, burner diameter, and composition. On the basis of a simple flame model, turbulent flashback involved a smaller effective penetration distance than laminar flashback. No current theoretical treatment predicts the observed pressure and diameter dependence of laminar and turbulent blowoff.

NACA TN 3994

STATIC STRENGTH OF CROSS-GRAIN 7075-T6 ALUMINUM-ALLOY EXTRUDED BAR CONTAINING FATIGUE CRACKS. Walter Illg and Arthur J. McEvily, Jr. April 1957. 25p. diagrs., photos., tabs. (NACA TN 3994)

Cross-grain specimens of 7075-T6 aluminum-alloy extrusion containing fatigue cracks of various lengths were subjected to static tests to determine residual static strength. Small cracks resulted in disproportionately large reductions of static strength. Comparison of the results with those for the with-grain direction revealed no significant difference. However, it is cautioned that cases may arise for 7075-T6 or for other materials where the cross-grain residual static strength is substantially inferior. The effects of biaxiality and ductility on notch sensitivity under static loading are discussed in appendixes.

Aeronautical Research Council (Gt. Brit.) BASE PRESSURES IN SUPERSONIC FLOW. G. E. Gadd, D. W. Holder, and J. D. Regan. 1956. 26p. diagrs., photos. ARC CP 271. (Ask for N-48302*)

The aim of the work is to throw light on the fundamental processes of the flow rather than to accumulate ad hoc data. Hence, only simple model shapes were investigated. These shapes are: two-dimensional wedges with base to chord ratios of one-fourth and one-eighth, cones of 10° semiangle, and cone-cylinder bodies of revolution with 30° semi-angle heads and lengths of 3 and 7 diameters. The base pressure behind a shallow two-dimensional step was measured at $M = 3$, and that behind a wedge on a plate at $M = 3$ and 4.

CALCULATED AERODYNAMIC FORCES ON A SWEPTBACK UNTAPERED WING OSCILLATING IN INCOMPRESSIBLE FLOW. D. L. Woodcock. December 1956. 21p. diagr., tabs. RAE Structures 217. (Ask for N-48421*)

The air forces are given for an untapered wing of aspect ratio 2 and sweepback 40° oscillating with symmetric distortion modes in incompressible flow. The results are for frequency parameters of 0(0.6)1.8. These are presented both as influence matrixes based on the displacement at a particular set of points and also as overall derivatives for modes of the form η^n for $n = 0(1)4$ where η is a nondimensional spanwise coordinate. The method used was the vortex lattice method. The standard lattice was modified by making the mesh size (in a chordwise direction) adjacent to the leading edge smaller than that over the main part of the wing. Comparison is made with some values obtained by a variant of the Multhopp method and the agreement is good. An appendix shows how the vortex lattice method is modified to obtain the virtual inertias.

MULTI-CHANNEL SLIP RINGS FOR STRESS AND TEMPERATURE MEASUREMENT. R. Chaplin. December 1956. 19p. diagrs., photo. NGTE Memo. M.289. (Ask for N-48426*)

The development of the various types of slipring is outlined in the text and the design of a brush and ring type of slipring is discussed in detail. It is shown that a slipring unit of this type can be made sufficiently robust to be a permanent part of the instrumentation of any rig. A highly stable contact potential is obtained in this design making possible stress measurements below 1/2 ton/sq in. in steel and temperature measurements with errors of less than 1° C using chromel-alumel thermocouples.

AN APPROXIMATE MEANS OF DETERMINING THE AXIAL FLAME TEMPERATURE PATTERN WITHIN A ROCKET ENGINE COMBUSTION CHAMBER.
L. J. Purchase and H. Walder. November 1956. 15p. diagrs., photo., tabs. RAE Tech.Note RPD 149. (Ask for N-48427*)

A knowledge of the position and temperature of the flame front in a combustion chamber is of value in the development of rocket engines. This note describes a method of obtaining the approximate position of the flame front in a combustion chamber.

BRITISH REPORTS

Metal rods of differing melting points are encastred at one end to the injector plate so that they lie parallel and close to the axis of the combustion chamber. The length of each rod remaining after a test gives an indication of the temperature at particular points within the chamber.

FATIGUE STRENGTH OF ALUMINIUM ALLOY LUGS (UNBUSHED) WITH AND WITHOUT INTERFERENCE FIT PINS. ALLOYS D.T.D.364 AND D.T.D.363. W. A. P. Fisher and H. Yeomans. November 1956. 21p. diagrs., photo., tabs. RAE Tech.Note Structures 209. (Ask for N-48429*)

The results of fatigue tests in pulsating tension are given for lug specimens in D.T.D.364 and D.T.D. 363 materials. Tests were done at mean stresses of 5.0 and 7.5 tons/in.^{2} and, in the case of D.T.D. 364 only, also at zero mean stress. With a few exceptions, the lugs with interference fit pins had a much longer endurance than those with push fit pins; the improvement was less at a mean stress of 7.5 tons/in.^{2} than at 5 tons/in.^{2} and was more consistent for the D.T.D.364 than for the D.T.D.363 lugs. The use of tapered pins is considered to be a more reliable method of controlling the desired amount of interference.

AN ANALOGUE COMPUTER FOR CONVECTIVE HEATING PROBLEMS. H. G. R. Robinson. October 1956. 24p. diagrs., photo., tabs. RAE Tech.Note GW 434. (Ask for N-48431*)

The computer was designed to assist in the solutions of kinetic heating problems which occur in guided weapon design. Its flexibility allows it to be used for a number of problems involving one-dimensional convective heating in a wall of finite thickness, providing the basic data such as the source temperature of the convective medium and the heat transfer coefficient in the region of interest are known. Completely arbitrary time varying functions of source temperatures and heat transfer coefficient are acceptable. This note describes the design and construction of the computer.

(Gt. Brit.) THE FULL SCALE AIR DRAG OF SOME FLYING BOAT SEAPLANES. A. G. Smith. February 1956. 71p. diagrs., photos., tabs. MAEE F/Res/265. (Ask for N-48432*)

An analysis has been made of the full-scale lift and drag characteristics of a number of British seaplanes. It is found that the drag coefficient and profile drag per 100 lb A.U.W. show progressive decreases, the best aircraft being the Princess. This is caused by improvement in hull design, reduction of drag with changeover to turbojet and turbopropeller propulsion units, and increase in aircraft size. The hull drag is of the order of 0.22 of the total profile drag for all the aircraft but the ratio of the turbulent skin friction drag of the idealized wing, hull, and tail unit to the actual profile drag increases to 0.73 for the Princess from 0.4 for the Sunderland. Further drag reductions would be possible if full use were made of recent methods of reducing hull air drag still further by detail fairing and increase of length-to-beam ratio.

THE MECHANICAL PROPERTIES AND POROSITY OF PARACHUTE FABRICS. A. Baker. September 1956. 61p. diagrs., photos., tabs. RAE Chem.507.
(Ask for N-48433*)

The various parachute textiles are described, and the effects of weave and construction on the porosity of fabrics are discussed. Their mechanical properties are assessed in relation to temperature, humidity, and rate of stressing; data are presented for yarns as well as fabrics. The hysteresis occurring in cyclic stressing is considered as an aspect of creep and recovery. The nature of porosity is clarified by means of light transmission and bubble pressure measurements; the latter are related to the threshold pressures for the commencement of airflow through wet fabrics. The repeated stressing of fabrics produces transient and permanent changes of porosity which may be explained in terms of the recoverable and residual components of deformation. The relative advantages of nylon, Terylene, and other fibers are discussed, for various conditions of use. The trends of future research are indicated.

AN INVESTIGATION INTO THE SUITABILITY OF SHOCK TESTING AS A MEANS OF THERMIONIC VALVE SELECTION FOR PULSE MODULATION TELEMETRY SENDERS. J. S. Whitall and P. C. Dench. November 1956. 13p. diagrs., photo., tabs. RAE Tech.Note TD 9. (Ask for N-48434*)

When CV 467's used as phantastrons in pulse telemetry senders are subjected to a sweep type vibration test there is a wide variation in the magnitude of microphony (approx. 100:1). It is therefore desirable that some simple and nondestructive method of valve selection should be possible prior to fitting to the sender. To make the test equipment as simple

BRITISH REPORTS

as possible, the valves were tested in an amplifier circuit and were excited by a shock produced by a light ebonite hammer falling, through a fixed angle, onto a duralumin block in which the valves were mounted. The peak microphony was observed on a cathode ray oscilloscope with a long persistence screen. Valves of different manufacturers and of different batches from the same manufacturer were tested and the results compared with the microphony obtained when the same valves were incorporated in pulse telemetry sender circuit and were subjected to a sweep-type vibration test.

THE DETERMINATION OF EXCESS ZINC IN NON-STOICHIOMETRIC ZINC OXIDE. H. J. Allsopp. November 1956. 19p. diagrs., tabs. RAE Met.92. (Ask for N-48435*)

This paper describes a hydrogen evolution technique whereby excess zinc in zinc oxide is determined. Under vacuum, the sample to be analyzed is dissolved in previously distilled hydrochloric acid. After solution, the acid is evaporated to insure that all the evolved gas is released. The gases are then analyzed for hydrogen content from the amount of which the excess metal is calculated. The method was standardized radiochemically and although the values obtained showed only about a 70-percent recovery, the method is believed to be absolute. The influence of grinding on the specimens has been studied. The sensitivity is estimated to be 0.1 p.p.m. $\frac{\text{excess zinc}}{\text{zinc oxide}}$ by weight. The zinc oxide specimens analyzed so far have been found to contain excess zinc within the range 0.2 - 18 p.p.m. $\frac{\text{excess zinc}}{\text{zinc oxide}}$ by weight. Reproducibility is good.

THE EXTENSIBILITY OF NYLON AND TERYLENE FABRICS UNDER CYCLIC STRESS. J. E. Swallow. November 1956. 17p. diagrs., tabs. RAE Tech. Note Chem.1289. (Ask for N-48437*)

The effect of cyclic uniaxial and biaxial stressing on the extension of several nylon and Terylene fabrics in plain and mock-leno weaves has been studied. Terylene has a greater strain hysteresis than nylon and its subsequent recovery is slower. Porosity changes in parachute fabrics under cyclic stressing are closely related to the extension under load and to the residual deformation after removal of stress.

AN ASSESSMENT OF THE ACCURACY OF A PRESSURE AND THRUST RECORDING SYSTEM EMPLOYING STRAIN GAUGE TRANSDUCERS, CARRIER AMPLIFIERS AND GALVANOMETER RECORDING. D. S. Dean and D. Young. November 1956. 34p. diagrs., tabs. RAE Tech.Note RPD 148. (Ask for N-48441*)

Tests to determine the accuracy of a recording system prior to installation in a rocket engine test bed are described. The system comprised strain gage

BRITISH REPORTS

pressure and thrust transducers, 2 kc/s carrier amplifiers with a frequency response linear to 100 c/s, and mirror galvanometers recording on photographic paper. Each element of the recording system was checked individually for stability and reproducibility of results. Where relevant, the accuracy of setting up the equipment and reading the results was determined. An estimate was then made of the accuracy to be expected with the complete equipment. During the tests, shortcomings became apparent in some of the instruments, and modifications are described to improve their performance. The complete equipment should have an accuracy of ±1/2 percent of full range when measuring pressure and ±1 percent when measuring thrust. All percentage errors quoted are related to the full usuable scale of the instrument or system, and unless otherwise stated are the maximum errors measured during tests and equivalent to about three standard deviations.

THE ηq METER, A RAPID INSTRUMENTAL METHOD OF COMBUSTION GAS ANALYSIS. F. H. Holderness. November 1956. 52p. diagrs., photos. NGTE R. 194. (Request N-48146*)

An account is given of the operating principles of an apparatus for rapid instrumental gas analytical measurements on combustion gases. An analysis can be completed with the apparatus in 6 to 10 minutes, using a stream of sample taken directly from a combustion chamber. The measurements made are of net carbon dioxide concentration, carbon monoxide, hydrogen, and total carbon dioxide. The last quantity is estimated after all carbon compounds in the sample have been fully oxidized to carbon dioxide in a furnace system. The direct indicating instruments which are incorporated into the meter are two infrared gas analyzers, for carbon dioxide and carbon monoxide measurements, and a sonic gas analyzer for hydrogen measurement. These instruments are described in a section of the report which gives complete constructional details of the meter. The measurements made can be used to derive values of combustion efficiency and fuel/air mixture strength. The calculations involved are included in an appendix. The meter is capable of handling gases from zones where combustion efficiency is in the range 0 to 100 percent and the mixture strength is in the range 0.0125 to 0.125.

BUBBLE-POINTS, FLAMMABILITY LIMITS AND FLASH POINTS OF PETROLEUM PRODUCTS. B. P. Mullins. November 1956. 34p. diagrs., tabs. NGTE R. 200. (Request N-48149*)

Relationships between the bubble points, flammability limits, and flash points of a fuel have been demonstrated numerically for four hydrocarbon fuels ranging from aviation spirit to gas oil. The mean molecular weights of the fuel vapors at the bubble points

BRITISH REPORTS

have been computed and several nomographic methods of presenting corrected bubble-point data are outlined with examples. Weak and rich flammability limits in air of the four fuels were calculated over a range of static pressures. The weak limit curve represents the conditions of the closed flash point test and so by differentiation of this curve a flash point pressure correction factor was obtained for each fuel. Excellent agreement between theoretical and measured values was found in all cases and a simple general rule for estimating flash points is given.

COMPARISON OF THE RESISTANCE TO SHOCK OF LUBRICATING FILMS. (Comparaison de la résistance au choc des films lubrifiants). F. Charron. January 1957. 19p. diagrs., photos., tabs. Translation of Ministere de l'Air Publications Scientifiques et Techniques No. 298, 1955. (Request N-38324*)

The purpose of this paper is to compare the protective properties of lubricating films with regard to continuous or suddenly applied forces. First, a test apparatus is described which has been especially constructed to take care of this double program. The result of steady-state tests shows that the viscosity under atmospheric pressure is a predominant factor whereas the coefficient of the increase of viscosity with pressure appears to be without interest, contrary to expectations. Tests under shock-loading conditions confirm these conclusions. In order to classify lubricants, we form the ratio of breaking-load of the film to the viscosity. This ratio is not constant; it is seen to be higher for certain oils which are particularly suitable for resisting large forces, due to properties little known or even unknown.

NACA RM A51D25

LOW-SPEED CHARACTERISTICS OF A WING HAVING 63° SWEEPBACK AND UNIFORM CAMBER. Leonard M. Rose. June 26, 1951. 18p. diagrs., photo., tabs. (NACA RM A51D25)

Low-speed wind-tunnel tests were made of a semispan wing with the leading edge swept back 63° and having the NACA 0010 airfoil section cambered for a lift coefficient of 1.0 perpendicular to the leading edge. The data, obtained at a Reynolds number of 3.7×10^6 based on the mean aerodynamic chord, include pressure distributions, lift, drag, and pitching-moment characteristics of the wing with and without a fuselage.

NACA RM A51D30

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - PLANE TRIANGULAR WING OF ASPECT RATIO 4 WITH 3-PERCENT-THICK, BICONVEX SECTION. John C. Heitmeyer. June 8, 1951. 26p. diagrs., photo. (NACA RM A51D30)

This report presents the results of an investigation to ascertain the lift, drag, and pitching moment of a wing-body combination having a triangular wing of aspect ratio 4 with 3-percent-thick, biconvex sections in streamwise planes. Results are shown for Mach numbers from 0.60 to 0.92 and from 1.20 to 1.70 at Reynolds numbers of 1.66 million and 2.91 million. Results are also shown for a Reynolds number of 4.15 million at Mach numbers up to 1.60.

NACA RM A51F21

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - PLANE TRIANGULAR WING OF ASPECT RATIO 4 WITH 3-PERCENT-THICK ROUNDED NOSE SECTION. John C. Heitmeyer and Ronald C. Hightower. August 1951. 17p. diagrs. (NACA RM A51F21)

This report presents the results of an investigation to ascertain the lift, drag, and pitching moment of a wing-body combination having a triangular wing of aspect ratio 4 with 3-percent-thick rounded nose sections in streamwise planes. Results are shown for Mach numbers from 0.60 to 0.92 and from 1.20 to 1.70 at Reynolds numbers of 2.91 million and 4.15 million.

NACA RM A51I18

AERODYNAMIC STUDY OF A WING-FUSELAGE COMBINATION EMPLOYING A WING SWEPT BACK 63° - EFFECTIVENESS OF AN INBOARD ELEVON AS A LONGITUDINAL- AND LATERAL-CONTROL DEVICE AT SUBSONIC AND SUPERSONIC SPEEDS. Frank A. Pfyl. December 1951. 38p. diagrs., photo., tabs. (NACA RM A51I18)

This reports presents the results of an experimental investigation of the effectiveness of a constant percent chord inboard elevon as a longitudinal- and lateral-control device for a wing-fuselage combination employing a wing swept back 63°. The investigation was made at Mach numbers of 0.6, 0.9, 1.2, 1.4, and 1.7 at a Reynolds number of 1.5 million. The results were compared with the experimental values obtained from tests at supersonic speeds, NACA RM A50A31a, 1950, and NACA RM A50K07, 1951, and at subsonic Mach numbers, NACA RM A8D20, 1948.

NACA RM A51K05

OBSERVATIONS OF UNSTEADY FLOW PHENOMENA FOR AN INCLINED BODY FITTED WITH STABILIZING FINS. Merrill H. Mead. January 1952. 23p. diagrs., photos. (NACA RM A51K05)

The dynamic rolling-moment characteristics of a slender inclined body of revolution in combination with a triangular cruciform tail have been investigated in the Ames 6- by 6-foot supersonic wind tunnel through a Mach number range of 0.9 to 1.7 at a free-stream Reynolds number of 0.84×10^6 based on maximum body diameter. Approximate measurements of the oscillating rolling moments of the model were obtained through an angle-of-attack range of 0° to 27°, and are presented for a series of Mach numbers. Photographs of the cross-flow field at the tail of the model, obtained by the use of the vapor-screen technique, are presented for several test conditions.

NACA RM A51K28

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - AN INVESTIGATION AT LARGE REYNOLDS NUMBERS OF THE LOW-SPEED CHARACTERISTICS OF SEVERAL WING-BODY COMBINATIONS. Donald W. Smith, Harry H. Shibata, and Ralph Selan. February 1952. 56p. diagrs., photos., tab. (NACA RM A51K28)

This paper contains the results of an investigation to ascertain the lift, drag, and pitching moment of nine wing-body combinations at large Reynolds numbers and low speeds. Results are presented for a range of Reynolds number from 4.9 million to 16.6 million at a constant Mach number of 0.25 for the models having wings of aspect ratio 2. The results for the models having wings of aspect ratios 3 and 4 are presented for a range of Reynolds number from approximately 2.4 million to 10.6 million at a constant Mach number of 0.25. The characteristics are also presented for a Mach number of 0.60 at a Reynolds number of 4.9 million for the models having wings of aspect ratio 2 and approximately 2.4 million for the models having wings of aspect ratios 3 and 4.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A52D01c

AERODYNAMIC CHARACTERISTICS OF TWO 25-PERCENT-AREA TRAILING-EDGE FLAPS ON AN ASPECT RATIO 2 TRIANGULAR WING AT SUBSONIC AND SUPERSONIC SPEEDS. John W. Boyd. July 1952. 82p. diagrs., photos., tabs. (NACA RM A52D01c)

The results of an experimental investigation of flap-type controls on a low-aspect-ratio triangular wing are presented for a constant-chord and a constant-percent-chord control surface. Two flap profiles were investigated, one of which had a ratio of trailing edge to hinge-line thickness of zero and the other of 0.50. The lift, drag, pitching moment, hinge moment, and rolling moments were obtained for Mach numbers of 0.60, 0.80, 0.90, 1.30, 1.53, and 1.70 at a constant Reynolds number of 3.0 million and for angles of attack from -4° to 16°.

NACA RM A52D21

TRANSONIC AERODYNAMIC CHARACTERISTICS OF THREE THIN TRIANGULAR WINGS AND A TRAPEZOIDAL WING, ALL OF LOW ASPECT RATIO. Horace F. Emerson and Bernard M. Gale. July 1952. 35p. diagrs., photos. (NACA RM A52D21)

An experimental investigation was conducted, using the transonic-bump technique, to determine the aerodynamic characteristics of the following three triangular wing models: two of aspect ratio 2 with the NACA 0005-63 and 0003-63 wing sections, respectively, and one of aspect ratio 3 with the NACA 0003-63 wing section. In addition an aspect-ratio-2 trapezoidal wing, obtained by removing the wing tip from the aspect-ratio-3 model, was investigated. Lift, drag, and pitching-moment coefficients are presented for Mach numbers ranging from 0.60 to 1.10. The Reynolds number for the tests varied from 2.1 to 2.8 million.

NACA RM A52D23

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - PLANE TAPERED WING OF ASPECT RATIO 3.1 WITH 3-PERCENT-THICK ROUNDED-NOSE SECTION. John C. Heitmeyer. July 1952. 25p. diagrs., tabs. (NACA RM A52D23)

This report presents the results of an investigation to ascertain the lift, drag, and pitching moment of a wing-body combination having a plane tapered wing of aspect ratio 3.1, taper ratio of 0.39 with 3-percent-thick, rounded-nose sections in streamwise planes. Results are shown for Mach numbers from 0.60 to 0.92 and from 1.20 to 1.90 at Reynolds numbers of 1.5 million and comparisons made with similar results for sharp-nose biconvex sections.

NACA RM A52E01

EFFECTS OF THREE TYPES OF BLUNT TRAILING EDGES ON THE AERODYNAMIC CHARACTERISTICS OF A PLANE TAPERED WING OF ASPECT RATIO 3.1, WITH A 3-PERCENT-THICK BICONVEX SECTION. Duane W. Dugan. July 1952. 34p. diagrs. (NACA RM A52E01)

Results of an experimental investigation of the effects of trailing-edge bluntness on the aerodynamic characteristics of a wing-body combination are given for Mach numbers both subsonic (0.6 to 0.925) and supersonic (1.2 to 1.7) and Reynolds numbers of 1.5 and 3.8 million. Three types of blunt-trailing-edge wings were investigated, each obtained by modifying a basic plane tapered wing of aspect ratio 3.1 having a 3-percent-thick, circular-arc, biconvex section.

NACA RM A52K14

EXPERIMENTAL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF AN AIR-TO-AIR MISSILE EMPLOYING CRUCIFORM WINGS AND TAIL OF RECTANGULAR PLAN FORM AT MACH NUMBERS OF 1.4 AND 1.9. Merrill H. Mead. February 1953. 31p. diagrs. (NACA RM A52K14)

The aerodynamic characteristics of a model of an air-to-air missile employing variable-incidence cruciform wings of rectangular plan form and a fixed cruciform tail of rectangular plan form, and the characteristics of its body-wing and body-tail components have been obtained, from a wind-tunnel investigation, for Mach numbers of 1.4 and 1.9. The results presented include normal-force, pitching-moment, and axial-force data for the body-wing-tail, body-wing, and body-tail combinations, and normal-force, hinge-moment, and axial-force data for the individual wing panels. The investigation was conducted at a constant Reynolds number of 1.51 million based on the wing chord. All of the results are presented in coefficient form plotted against angle of attack. No discussion of the results is included.

NACA RM A52L02

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - COMPARISON OF THREE WINGS OF ASPECT RATIO 2 OF RECTANGULAR, SWEPTBACK, AND TRIANGULAR PLAN FORM, INCLUDING EFFECTS OF THICKNESS DISTRIBUTION. Ronald C. Hightower. February 1953. 30p. diagrs., tabs. (NACA RM A52L02)

Three wing-body combinations of aspect ratio 2, of rectangular, sweptback, and triangular plan form, are compared at subsonic and supersonic Mach numbers. The effects of thickness distribution on the characteristics of the rectangular and sweptback wings are also shown. Data are presented in tabulated form for the rectangular wing at Reynolds numbers of 1.8 million and 4.4 million, the sweptback wing at Reynolds numbers of 1.9 million and 4.8 million, and the triangular wing at Reynolds numbers of 3.0 million and 7.5 million. A summary of the aerodynamic characteristics of the models at the highest Reynolds numbers is presented.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A52L15a

EFFECT OF VERTICAL POSITION OF THE WING ON THE AERODYNAMIC CHARACTERISTICS OF THREE WING-BODY COMBINATIONS. John C. Heitmeyer. February 1953. 56p. diagrs., photo., tabs. (NACA RM A52L15a)

An experimental wind-tunnel investigation has been made of three plane wings of aspect ratio 3, with 3-percent-thick sections each in combination with a body modified for off-the-center-line locations of the wing. The three wings were of the following plan forms: tapered unswept, tapered swept, and triangular. The lift, drag, and pitching-moment characteristics of each configuration were obtained for a range of Mach numbers from 0.61 to 0.91 and from 1.20 to 1.90. The data were obtained at constant Reynolds numbers per foot of 2.57 million and 4.00 million for all Mach numbers except 1.90. At this Mach number the maximum test Reynolds number per foot was limited to 2.57 million. The results at a Reynolds number per foot of 4.0 million are compared with results of the same wings mounted in a midwing position on a body of revolution of the same axial distribution of cross-sectional area as the body of the present investigation.

NACA RM A53C20

SUBSONIC STATIC LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A WING-BODY COMBINATION HAVING A POINTED WING OF ASPECT RATIO 2 WITH CONSTANT-PERCENT-CHORD TRAILING-EDGE ELEVONS. Donald W. Smith and Verlin D. Reed. May 1953. 143p. diagrs., photos., tab. (NACA RM A53C20)

Results of tests made to determine the static longitudinal stability of a pointed wing with an aspect ratio 2 and the effectiveness of trailing-edge elevons as a longitudinal control are presented in this report. The effectiveness of tabs in reducing elevon hinge moments is also included. The data were obtained for a range of Mach numbers from 0.24 to 0.95 at a constant Reynolds number of 3.0 million and for Reynolds numbers up to 15.0 million at a constant Mach number of 0.24.

NACA RM A53D28

A STUDY OF THE MOTION AND AERODYNAMIC HEATING OF MISSILES ENTERING THE EARTH'S ATMOSPHERE AT HIGH SUPERSONIC SPEEDS. H. Julian Allen and A. J. Eggers, Jr. August 1953. 62p. diagrs., photo. (NACA RM A53D28)

A simplified analysis of the velocity and deceleration history of missiles entering the earth's atmosphere at high supersonic speeds is presented. The results of this motion analysis are employed to indicate means available to the designer for minimizing aerodynamic heating. The heating problem considered involves not only the total heat transferred to a missile by convection, but also the maximum average and local time rates of convective heat transfer.

NACA RM A53D29

PERFORMANCE OF A NORMAL-SHOCK SCOOP INLET WITH BOUNDARY-LAYER CONTROL. Alson C. Frazer and Warren E. Anderson. June 1953. 31p. diagrs., photos. (NACA RM A53D29)

An experimental investigation was conducted with a normal-shock scoop inlet mounted on a flat plate and employing a boundary-layer-removal scoop. The performance of the main scoop and the boundary-layer scoop was determined for varying amounts of boundary-layer removal over a Mach number range from 1.35 to 1.75. The maximum net thrust was approximately equal to that for an ideal normal-shock inlet and occurred for a value of scoop height to boundary-layer thickness of about 70 percent. Extending the boundary-layer scoop forward of the main inlet was found to increase the stable range of subcritical mass-flow ratio.

NACA RM A55D07

ESTIMATION OF INCREMENTAL PITCHING MOMENTS DUE TO TRAILING-EDGE FLAPS ON SWEPT AND TRIANGULAR WINGS. Harry A. James and Lynn W. Hunton. June 1955. 31p. diagrs., tab. (NACA RM A55D07)

A method is shown by which the incremental pitching moment of swept and triangular wings due to flaps at low speeds can be estimated by using two-dimensional data in conjunction with span-loading theory. Comparisons of estimated and experimental values of flap pitching-moment increments for some 58 cases indicate a mean deviation of about 0.02 C_m. Some two-dimensional flap parameters pertinent to the application of the method are summarized in graphical form.

NACA RM A55D18

A FLIGHT INVESTIGATION AT TRANSONIC SPEEDS OF A MODEL HAVING A TRIANGULAR WING OF ASPECT RATIO 3. Maurice D. White. June 1955. 39p. diagrs., photos., tabs. (NACA RM A55D18)

The longitudinal aerodynamic characteristics of a model having a triangular wing of aspect ratio 3 and a 45° sweptback horizontal tail located in the extended wing chord plane were investigated at transonic speeds by the free-falling recoverable-model technique. Static and dynamic longitudinal-stability data, and force and moment data for the major components of the model are presented for Mach numbers from 0.80 to 1.12 and angles of attack up to 16° to 22°, depending on the Mach number.

NACA RM E52D16, by Barson.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E55D04

STATIC INVESTIGATION OF SEVERAL JET DEFLECTORS FOR LONGITUDINAL CONTROL OF AN AIRCRAFT. Alfred S. Valerino. June 1955. 19p. diagrs., photos. (NACA RM E55D04)

Results of a static investigation of several radially curved jet deflectors mounted at the exit of a shrouded iris-flap ejector indicate that, when the deflectors were alined with the trailing edge of the afterbody shroud (deflector removed from jet boundary), the lowest lifts per unit deflector area were obtained with the deflector having the shortest length. When the deflectors were alined with the trailing edge of the ejector shrouded iris flap (deflector at jet boundary), the highest lifts per unit deflector area were obtained with the deflector having the shortest length.

NACA RM L7D11, by Kuhn and Polhamus.

NACA RM L51D30

AN INVESTIGATION OF FLOW CHARACTERISTICS AT MACH NUMBER 4.04 OVER 6- AND 9-PERCENT-THICK SYMMETRICAL CIRCULAR-ARC AIRFOILS HAVING 30-PERCENT-CHORD TRAILING-EDGE FLAPS. Edward F. Ulmann and Douglas R. Lord. July 1951. 67p. diagrs., photos., tab. (NACA RM L51D30)

Section data obtained from wind-tunnel tests at Mach number 4.04 and Reynolds numbers of about 5.0×10^6 and 8.4×10^6 are presented for 6- and 9-percent-thick symmetrical circular-arc airfoils with 30-percent-chord trailing-edge flaps. Pressure distributions, schlieren photographs, and force and moment coefficients are included.

NACA RM L52D15a

SOME EFFECTS OF FIN PLAN FORM ON THE STATIC STABILITY OF FIN-BODY COMBINATIONS AT MACH NUMBER 4.06. Edward F. Ulmann and Robert W. Dunning. July 1952. 20p. diagrs., photos. (NACA RM L52D15a)

The results of an investigation in the Langley 9- by 9-inch Mach number 4 blowdown tunnel into the effects of fin plan form on the static stability of fin-body configurations at Mach number 4.06 are presented. Fins of three plan forms were tested as pairs of tail fins on fineness-ratio-9 and -12 ogive-cylinder bodies of revolution. Plan forms were rectangular, delta, and the trapezoidal plan form of the vertical tail of the Bell X-2 airplane. The results were compared with some existing fin-body interaction theories and an alteration to these theories is presented which improves their predictions for blunt bodies at high Mach numbers.

NACA RM L52D29

FREE-FLIGHT INVESTIGATION OF THE ZERO-LIFT DRAG OF SEVERAL WINGS AT SUPERSONIC MACH NUMBERS EXTENDING TO 2.6. Russell N. Hopko and Carl A. Sandahl. December 1952. 19p. diagrs., photos., tabs. (NACA RM L52D29)

The zero-lift drag of some delta and swept wings of current interest was obtained at Mach numbers extending to 2.6. The 60° delta wings had the lowest drag. At Mach numbers above 2.1, the drag coefficients of the 4.5-percent-thick, 10° swept wing and the 5.8-percent-thick, 63° swept tapered wing were about equal.

NACA RM L52L30

EFFECTS OF WING ELASTICITY ON THE AERODYNAMIC CHARACTERISTICS OF AN AIRPLANE CONFIGURATION HAVING 45° SWEPTBACK WINGS AS OBTAINED FROM FREE-FLIGHT ROCKET-MODEL TESTS AT TRANSONIC SPEEDS. A. James Vitale. January 1953. 49p. diagrs., photos., tab. (NACA RM L52L30)

Flight tests were conducted on two rocket-propelled models of an airplane configuration with 45° sweptback wings of aspect ratio 4 and having different stiffnesses. The longitudinal stability, lift, and drag characteristics were determined over a Mach number range of 0.95 to 1.3. A comparison was made between calculated and experimental aeroelastic effects on lift and longitudinal stability.

NACA RM L53D03

AERODYNAMIC CHARACTERISTICS AT MACH NUMBER 4.04 OF A RECTANGULAR WING OF ASPECT RATIO 1.33 HAVING A 6-PERCENT-THICK CIRCULAR-ARC PROFILE AND A 30-PERCENT-CHORD FULL-SPAN TRAILING-EDGE FLAP. Robert W. Dunning and Edward F. Ulmann. May 1953. 26p. diagrs., tab. (NACA RM L53D03)

The results of force tests at a Mach number of 4.04 and a Reynolds number of 8×10^6 of a rectangular-plan-form wing of aspect ratio 1.33 having a 6-percent-thick circular-arc profile and a 30-percent-chord full-span trailing-edge flap are presented and compared with previously obtained two-dimensional data and the predictions of an existing theoretical method. Data presented included lift, drag, pitching-moment, rolling-moment, and wing-root bending-moment coefficients for the wing and flap-hinge-moment coefficients and are presented through an angle-of-attack range of 0° to 10° and a flap-deflection range of $\pm 12^\circ$.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53D10

A TRANSONIC INVESTIGATION BY THE FREE-FALL METHOD OF AN AIRPLANE CONFIGURATION HAVING 45° SWEPTBACK WING AND TAIL SURFACES. Stanley Faber and John M. Eggleston. June 1953. 41p. diagrs., photos., tabs. (NACA RM L53D10)

As part of a general investigation to obtain the characteristics of airplanes in the transonic range, the Langley Laboratory, by using the free-fall technique, has tested an airplane configuration having 45° sweptback wing and tail surfaces. The model was equipped with an all-movable horizontal tail that was stepped cyclically during the drop in order to vary the angle of attack. In this manner, the lift, drag, and longitudinal static and dynamic stability and control characteristics were obtained at various operating lift coefficients (up to 0.26) over a Mach number range of 0.5 to 1.21.

NACA RM L53D24

AN EXPERIMENTAL INVESTIGATION OF THE EFFECT OF VARIOUS PARAMETERS INCLUDING TIP MACH NUMBER ON THE FLUTTER OF SOME MODEL HELICOPTER ROTOR BLADES. George W. Brooks and John E. Baker. June 1953. 68p. diagrs., photos., tabs. (NACA RM L53D24)

Experimental studies have been made to evaluate the effects of parameters such as Mach number, blade angle, and structural damping on the flutter of model helicopter rotor blades in the hovering condition. The model blades had NACA 23012 and 23018 airfoil sections and each was tested at chordwise center-of-gravity locations of approximately 27.5 and 37 percent. Data were obtained at test-medium densities ranging from 0.0012 to 0.0030 slug per cubic foot and at various pitch angles up into the stall. Mixtures of air and Freon-12 were used for the test medium in order to extend the tip Mach number range of the tests to slightly above unity.

NACA RM L53D27

EFFECT OF VARIATIONS IN REYNOLDS NUMBER ON THE AERODYNAMIC CHARACTERISTICS OF THREE BOMB OR STORE SHAPES AT A MACH NUMBER OF 1.62 WITH AND WITHOUT FINS. Robert W. Rainey. June 1953. 40p. diagrs., photos., tab. (NACA RM L53D27)

Results of tests made in the Langley 9-inch supersonic tunnel of three bomb shapes with two sets of cruciform fins as well as without fins are presented. These investigations were made at a Mach number of 1.62 and at Reynolds numbers of from 0.40×10^6 to 9.70×10^6 based upon the closed body lengths. The maximum angle-of-attack range was from -4° to 10°. The results are presented in the form of normal forces, chord forces, and pitching moments with analyses made of the effects of variations of angle of attack and Reynolds number upon the measured characteristics as well as upon the center-of-pressure position and fin effectiveness.

NACA RM L54D01

A WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE LATERAL CONTROL CHARACTERISTICS OF VARIOUS PLAIN SPOILER CONFIGURATIONS ON A 3-PERCENT-THICK 60° DELTA WING. Harleth G. Wiley. May 1954. 45p. diagrs., tabs. (NACA RM L54D01)

Results are presented of wind-tunnel investigations at Mach numbers of 0.60 to 0.94 and angles of attack of -2° to about 24° to determine the lateral control characteristics of spoilers with various wing chordwise and spanwise locations and spoiler spans and deflections on a thin 60° delta wing of NACA 65A003 airfoil section parallel to free stream.

NACA RM L54D09

SUBSONIC FLIGHT INVESTIGATION OF METHODS TO IMPROVE THE DAMPING OF LATERAL OSCILLATIONS BY MEANS OF A VISCOUS DAMPER IN THE RUDDER SYSTEM IN CONJUNCTION WITH ADJUSTED HINGE-MOMENT PARAMETERS. Harold L. Crane, George J. Hurt, Jr., and John M. Elliott. June 1954. 46p. diagrs., photos., tab. (NACA RM L54D09)

Results are presented of a flight investigation at subsonic speeds of a method to improve the damping of lateral oscillations by means of a viscous damping cylinder used in the rudder system in conjunction with adjusted hinge-moment parameters. The single-degree-of-freedom analysis used as a guide to adjust the parameters is included. A brief discussion of related problems which may result from the application of such a viscous damping device is given. The results of rudder trailing-edge strips to control rudder floating tendency are presented.

NACA RM L54D12a

SUPERSONIC FLUTTER OF A 60° DELTA WING ENCOUNTERED DURING THE FLIGHT TEST OF A ROCKET-PROPELLED MODEL. William T. Lauten, Jr., and Joseph H. Judd. June 1954. 20p. diagrs., photos., tabs. (NACA RM L54D12a)

Results of a flight test of a 60° delta-wing airplane configuration indicated wing flutter at a Mach number of about 1.7, continuing through the maximum Mach number of 2.08 to telemeter failure at a Mach number of 1.4. The ratio of flutter frequency to torsional frequency was approximately 1.0 from start to peak speed and gradually decreased as the model speed decreased. The flight time history, natural frequencies of vibration, and structural influence coefficients of the wing, and the mass, moment of inertia, and center of gravity of streamwise strips of the wing are presented. Also presented are calculated mode shapes and frequencies. A comparison is made with results obtained from a flight test of a wing similar in plan form but weaker structurally which fluttered over the same speed range.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L54D15

EXPERIMENTAL EVIDENCE OF SUSTAINED COUPLED LONGITUDINAL AND LATERAL OSCILLATIONS FROM A ROCKET-PROPELLED MODEL OF A 35° SWEPT WING AIRPLANE CONFIGURATION. James H. Parks. May 1954. 28p. diagrs., photos., tab. (NACA RM L54D15)

Flight tests of a rocket-propelled model of a representative 35° sweptback airplane design indicate the existence of coupled longitudinal and lateral oscillations. The flight time history is presented and the primary sources of the cross-coupling moments are shown.

NACA RM L54D26a

FLIGHT INVESTIGATION OF AN AILERON AND A SPOILER ON A WING OF THE X-3 AIRPLANE PLAN FORM AT MACH NUMBERS FROM 0.5 TO 1.6. Roland D. English. June 1954. 16p. diagrs., photos. (NACA RM L54D26a)

A free-flight investigation has been made of the rolling effectiveness and drag of two types of controls on a wing of the X-3 airplane plan form. The controls investigated include a 25-percent-chord aileron deflected 5° and a 2-percent-chord trailing-edge spoiler. The tests were made at essentially zero angle of attack and zero angle of yaw over a Mach number range from 0.5 to 1.6.

NACA RM L54D28

FLIGHT INVESTIGATION TO DETERMINE LIFT AND DRAG CHARACTERISTICS OF A CANARD RAM-JET MISSILE CONFIGURATION IN THE MACH NUMBER RANGE OF 0.8 TO 2.0. Abraham A. Gammal and Thomas L. Kennedy. June 1954. 20p. diagrs., photos. (NACA RM L54D28)

A flight investigation, employing two rocket-boosted models, has been conducted on a canard ram-jet missile configuration consisting of two ram jets mounted on a composite wing of 0° and 60° leading-edge sweepback and a delta-type canard of 60° sweepback. Lift and drag data were obtained at low values of lift in the Mach number range of 0.8 to 2.0.

NACA RM L54L15

TURBULENT CONVECTIVE HEAT-TRANSFER COEFFICIENTS MEASURED FROM FLIGHT TESTS OF FOUR RESEARCH MODELS (NACA RM-10) AT MACH NUMBERS FROM 1.0 TO 3.6. Leo T. Chauvin and Joseph P. Maloney. March 1955. 30p. diagrs., photo., tabs. (NACA RM L54L15)

Free-flight tests at supersonic speeds have been made to determine the heat-transfer coefficient evaluated from measured skin temperatures along a parabolic body of revolution. The Mach number ranged from 1.0 to 3.6 and the Reynolds number ranged from 6×10^6 to 150×10^6. The experimental heat-transfer data from four flight tests are in agreement with previous measurement made on the NACA RM-10 research model. The measured recovery factors were lower than those predicted by theory for turbulent boundary layers. The experimental data were also in agreement with the theory of NACA RM L52H04 for heat transfer in a compressible flow. When a modified Reynolds analogy was used, the measured heat transfer was in agreement with the average measured skin friction.

NACA RM L55D27

EFFECTS OF WING-MOUNTED TANK-TYPE STORES ON THE LOW-LIFT BUFFETING AND DRAG OF A SWEPT-WING AIRPLANE CONFIGURATION BETWEEN MACH NUMBERS OF 0.8 AND 1.3. Homer P. Mason. October 1955. 34p. diagrs., photos., tabs. (NACA RM L55D27)

Results of rocket-powered model tests of a 45° swept-wing airplane configuration with two different underwing fuel-tank installations are presented and compared with previously reported data to show the effect of fuel-tank installations on the buffeting and drag, including an evaluation of interference effects, of the configuration.

NACA RM L55D29

INVESTIGATION OF THE EFFECTS OF MODEL SCALE AND STREAM REYNOLDS NUMBER ON THE AERODYNAMIC CHARACTERISTICS OF TWO RECTANGULAR WINGS AT SUPERSONIC SPEEDS IN THE LANGLEY 9-INCH SUPERSONIC TUNNEL. Donald E. Coletti. June 1955. 32p. diagrs. (NACA RM L55D29)

Results of an investigation made in the Langley 9-inch supersonic tunnel are presented to determine the effect of model scale and stream Reynolds number on the aerodynamic characteristics of two aspect-ratio 1.80 rectangular wings having thickness ratios of 0.059. The tests were conducted at Reynolds numbers varying between 0.13×10^6 and 2.96×10^6 and at Mach numbers of 1.62, 1.94, and 2.41. The angle of attack was varied between 7° and -6°. Comparisons are made with theory.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1282

A SPECIAL METHOD FOR FINDING BODY DISTORTIONS THAT REDUCE THE WAVE DRAG OF WING AND BODY COMBINATIONS AT SUPERSONIC SPEEDS. Harvard Lomax and Max. A. Heaslet. 1956. ii, 38p. diagrs., tabs. (NACA Rept. 1282. Supersedes RM A55B16)

For a given wing and supersonic Mach number, the problem of shaping an adjoining fuselage so that the combination will have a low wave drag is considered. Only fuselages that can be simulated by singularities (multipoles) distributed along the body axis are studied. However, the optimum variations of such singularities are completely specified in terms of the wing geometry.

NACA Rept. 1283

EXTRAPOLATION TECHNIQUES APPLIED TO MATRIX METHODS IN NEUTRON DIFFUSION PROBLEMS. Robert R. McCready. 1956. ii, 10p. diagrs. (NACA Rept. 1283. Supersedes TN 3511)

An iterative scheme is developed for the matrix solution of the type of characteristic-value problem arising from homogeneous linear equations. The scheme is shown to minimize a suitable form at each step. Extrapolation techniques for speeding convergence are developed and refined. An example from nuclear-reactor theory is presented.

NACA Rept. 1292

INTENSITY, SCALE, AND SPECTRA OF TURBULENCE IN MIXING REGION OF FREE SUBSONIC JET. James C. Laurence. 1956. ii, 27p. diagrs., photo., tab. (NACA Rept. 1292. Supersedes TN 3561; TN 3576)

The intensity of turbulence, the longitudinal and lateral correlation coefficients, and the spectra of turbulence in a 3.5-inch-diameter free jet were measured with hot-wire anemometers at exit Mach numbers from 0.2 to 0.7 and Reynolds numbers from 192,000 to 725,000. The results of these measurements show the following: (1) Near the nozzle (distances less than 4 or 5 jet diameters downstream of the nozzle) the intensity of turbulence, expressed as percent of core velocity, is a maximum at a distance of approximately 1 jet radius from the center line and decreases slightly with increasing Mach and/or Reynolds number. At distances greater than 8 jet diameters downstream of the nozzle, however, the maximum intensity moves out and decreases in magnitude until the turbulence-intensity profiles are quite flat and approaching similarity. (2) The lateral and longitudinal scales of turbulence are nearly independent of Mach and/or Reynolds number and in the mixing zone near the jet vary proportionally with distance from the jet nozzle. (3) Farther downstream of the jet the longitudinal scale reaches a maximum and then decreases approximately linearly with distance. (4) Near the nozzle the lateral scale is much smaller than the longitudinal and does not vary with distance from the center line, while the longitudinal scale is a maximum at a distance from the center line of about 0.7 to 0.8 of the jet radius. (5) Farther downstream this maximum moves out from the center line. (6) A statistical analysis of the correlograms and spectra yields a "scale" which, although different in magnitude from the conventional, varies similarly to the ordinary scale and is easier to evaluate.

NACA RM 57B25

PROPAGATION OF SOUND INTO A WIND-CREATED SHADOW ZONE. David C. Pridmore-Brown, Massachusetts Institute of Technology. April 1957. 25p. diagrs. (NACA RM 57B25)

The general wave equation is derived governing the propagation of sound in a stratified moving medium, the velocity of which varies only along one coordinate. Under the assumption that the flow velocity is small and slowly varying, a simplified equation is adopted which is satisfactory for the present application. A solution is found to this equation corresponding to the pressure field around a spherical source located above a plane ground in a horizontal wind whose velocity increases with altitude. It is shown that within the acoustic shadow that forms on the upwind side of such a source the pressure field is similar to that which is obtained in the corresponding problem of a sound source in a temperature gradient. An expression is derived for the rate of attenuation within a shadow which is brought about by the presence of both a wind and a temperature gradient.

NACA RM E57B14

A REVIEW OF THE PHYSICAL AND THERMODYNAMIC PROPERTIES OF BORIC OXIDE. Paul C. Setze. April 1957. 25p. diagrs., photo., tabs. (NACA RM E57B14)

The properties of boric oxide (B_2O_3) are presented in tabular and graphical form and include specific heat, sensible enthalpy, total enthalpy, entropy, latent heat of vaporization, and vapor pressure, (for the crystal, liquid, and vapor states) and specific gravity, surface tension, viscosity, and electrical resistivity. In addition, basic molecular and structural data are included. The data presented are discussed, and the reasons are given for choosing one set of data in preference to another.

NACA TM 1429

WALL INTERFERENCE IN A PERFORATED WIND TUNNEL. (Studio dell'Interferenza delle Gallerie Aerodinamiche con Pareti a Fessure). Riccardo Brescia. May 1957. 28p. diagrs. (NACA TM 1429. Translation from Accademia delle Scienze di Torino, Atti, v. 87, 1952-1953)

The interference of perforated walls on sources and doublets is treated by showing that as the dimensions of a cascade wall become small, the cascade wall approximates a vortex sheet. Special singularities called "reflected" and "transmitted" are developed to simulate the interference of the vortex sheet on the original singularities. Equations are given for the interference of two perforated walls on the flow fields of two-dimensional sources and doublets.

NACA TN 3878

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF RANDOM GUST LOADS. PART I - AERODYNAMIC TRANSFER FUNCTION OF A SIMPLE WING CONFIGURATION IN INCOMPRESSIBLE FLOW. Raimo J. Hakkinen and A. S. Richardson, Jr., Massachusetts Institute of Technology. May 1957. 64p. diagrs., photos. (NACA TN 3878)

Sinusoidally oscillating downwash and lift produced on a simple rigid airfoil were measured and compared with calculated values. Statistically stationary random downwash and the corresponding lift on a simple rigid airfoil were also measured and the transfer functions between their power spectra determined. The random experimental values are compared with theoretically approximated values. Limitations of the experimental technique and the need for more extensive experimental data are discussed.

NACA TN 3879

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF RANDOM GUST LOADS. PART II - THEORETICAL FORMULATION OF ATMOSPHERIC GUST RESPONSE PROBLEM. A. S. Richardson, Jr., Massachusetts Institute of Technology. May 1957. 50p. diagrs., tab. (NACA TN 3879)

Equations of motion are derived for the dynamic response of an aircraft to random atmospheric gust loads. These equations include the degrees of freedom of plunging, pitching, rolling, and an arbitrary number of elastic normal modes. Solutions are obtained by use of the Dirac delta function and certain cross correlations and autocorrelations enter the analysis. Several simplified cases are analyzed. Comparisons are made with results of the sharp-edged-gust formula.

NACA TN 3903

AN EXPERIMENTAL HYDRODYNAMIC INVESTIGATION OF THE INCEPTION OF VORTEX VENTILATION. John A. Ramsen. April 1957. 31p. diagrs., photos. (NACA TN 3903)

Results are presented from a hydrodynamic investigation of the inception of vortex ventilation on modified-flat-plate rectangular lifting surfaces of aspect ratio 0.25 differing in scale and thickness ratio. Two types of bubble-formation processes are described. Inception speeds were correlated for bubble formation in the high angle-of-attack range by using the Froude number and for that in the low angle-of-attack range by expressing the speed as a function of the thickness ratio.

NACA TN 3920

EFFECT OF SPANWISE VARIATIONS IN GUST INTENSITY ON THE LIFT DUE TO ATMOSPHERIC TURBULENCE. Franklin W. Diederich and Joseph A. Drischler. April 1957. 56p. diagrs., tabs. (NACA TN 3920)

The effect of spanwise variations in gust intensity on the power spectrum directly due to atmospheric turbulence is calculated for several analytic approximations to the correlation function or power spectra of atmospheric turbulence, for several spanwise weighting functions (span loadings), and for various angles of sweepback.

NACA TN 3934

EXPERIMENTAL STUDY OF HEAT TRANSFER TO SMALL CYLINDERS IN A SUBSONIC, HIGH-TEMPERATURE GAS STREAM. George E. Glawe and Robert C. Johnson. APPENDIX C: METHOD USED TO COMPUTE VISCOSITY AND THERMAL CONDUCTIVITY OF COMBUSTION GAS MIXTURES. Richard S. Brokaw and Robert C. Johnson. May 1957. 21p. diagrs., photo. (NACA TN 3934)

A Nusselt-Reynolds number relation for cylindrical thermocouple wires in crossflow was obtained from the experimental determination of time constants. Tests were conducted in exhaust gas over a temperature range of 2000° to 3400° R, a Mach number range of 0.3 to 0.8, and a static-pressure range from 2/3 to 1-1/3 atmospheres, yielding a Reynolds number range of 450 to 3000. The correlation obtained is $Nu = (0.428 \pm 0.003)\sqrt{Re^*}$ with average deviations of a single observation of 8.5 percent. This relation is the same as one previously reported for room-temperature conditions.

CURRENT NACA RESEARCH REPORTS

NACA TN 3935

HYDROGEN-OXYGEN EXPLOSIONS IN EXHAUST DUCTING. Paul M. Ordin. April 1957. 31p. diagrs., photos., tab. (NACA TN 3935)

An investigation was undertaken to determine the detonation combustion pressure of hydrogen-oxygen mixtures at a pressure of 1 atmosphere in a 2-foot-diameter duct. Detonation pressures of about 315 lb/sq in. abs were obtained at oxidant-fuel mole ratios of 0.82. Water sprays distributed through sections of the duct did not prevent a detonation but did reduce the peak pressures. The total pressures obtained on various designs of 90° steel elbows by the detonation were about 900 lb/sq in. abs. A design stress of 38,400 psi and suitable supporting members for the duct elbows contained the detonation without any damage to the structure.

NACA TN 3950

CHARTS FOR THE ANALYSIS OF FLOW IN A WHIRLING DUCT. Robert A. Makofski. May 1957. 21p. diagrs. (NACA TN 3950)

Charts are developed for the analysis of flow in a whirling constant-diameter duct. These charts permit the determination of the duct-exit Mach number, or the Mach number at any point along the duct, for practical ranges of duct-inlet Mach number, duct-tip Mach number, friction factor, ratio of ambient temperature to duct-flow total temperature, ratio of duct-tip radius to duct hydraulic diameter, and heat conductivity through the duct wall and surrounding material. The method of using the charts is illustrated through the computation of a sample problem.

NACA TN 3956

LIFT AND MOMENT RESPONSES TO PENETRATION OF SHARP-EDGED TRAVELING GUSTS, WITH APPLICATION TO PENETRATION OF WEAK BLAST WAVES. Joseph A. Drischler and Franklin W. Diederich. May 1957. 85p. diagrs., tabs. (NACA TN 3956)

The lift and moment responses to penetration of sharp-edged traveling gusts are calculated for wings in incompressible and supersonic two-dimensional flow, for wide delta and rectangular wings in supersonic flow, and for very narrow delta wings. By using the two-dimensional indicial-lift functions, some calculations of normal-acceleration response are made for two mass ratios. The relation between gusts traveling at supersonic speeds and blast waves is indicated.

NACA TN 3959

CASCADE INVESTIGATION OF A RELATED SERIES OF 6-PERCENT-THICK GUIDE-VANE PROFILES AND DESIGN CHARTS. James C. Dunavant. May 1957. 48p. diagrs., tabs. (NACA TN 3959. Supersedes RM L54I02)

A new guide-vane blade series for high critical speeds of improved section characteristics has been derived. Low-speed cascade tests were made of four blade sections of this series at solidities of 0.75, 1.00, and 1.50. From these tests, design angles of attack were selected and are presented as a method of determining camber for guide-vane turning angles as high as 50°. The results of a number of simple computations made to estimate the high-speed characteristics of the blade series are presented.

NACA TN 3961

EFFECTS OF FUSELAGE NOSE LENGTH AND A CANOPY ON THE STATIC LONGITUDINAL AND LATERAL STABILITY CHARACTERISTICS OF 45° SWEPTBACK AIRPLANE MODELS HAVING FUSELAGES WITH SQUARE CROSS SECTIONS. Byron M. Jaquet and H. S. Fletcher. April 1957. 47p. diagrs., photos., tabs. (NACA TN 3961)

Results are presented of an investigation made in the Langley stability tunnel to determine the effect of fuselage nose length and canopy on the static longitudinal and lateral characteristics of complete models (fuselage fineness ratio varied from 7.41 to 10.18) over an angle-of-attack range of -10° to 32°. The effects of the canopy and wing on the tail contribution to the static longitudinal and static directional stability characteristics were determined for a fuselage of fineness ratio 9.26. Data were also obtained with the fuselage nose blunted for a complete model originally having the pointed-nose fuselage of fineness ratio 9.26. Data through a sideslip-angle range of -24° to 24° were obtained at a few angles of attack. The test Mach number was 0.13 and the Reynolds number, based on the wing mean aerodynamic chord, was 0.83×10^6.

NACA TN 3964

THE LINEARIZED SUBSONIC FLOW ABOUT SYMMETRICAL NONLIFTING WING-BODY COMBINATIONS. John B. McDevitt. April 1957. 67p. diagrs. (NACA TN 3964)

A theory is presented for calculating the linearized subsonic flow about symmetrical, nonlifting wing-body combinations. The wing is represented by a planar distribution of sources and the required boundary condition of tangential flow at the body surface is satisfied by placing along the body center line axial distributions of sources and multipoles.

CURRENT NACA RESEARCH REPORTS

NACA TN 3965

MEASUREMENTS OF THE NONLINEAR VARIATION WITH TEMPERATURE OF HEAT-TRANSFER RATE FROM HOT WIRES IN TRANSONIC AND SUPERSONIC FLOW. Warren Winovich and Howard A. Stine. April 1957. 33p. diagrs., photo., tab. (NACA TN 3965)

An experimental investigation was undertaken to determine heat-loss characteristics of hot wires operating at Mach numbers between 0.5 and 2.5. At constant temperature potential, the Nusselt number is given as a function of the Reynolds number and Mach number. The influence of Mach number on nonlinearity between temperature and heat-transfer rate was determined at various Reynolds numbers.

NACA TN 3966

THEORETICAL INVESTIGATION OF THE EFFECTS OF CONFIGURATION CHANGES ON THE CENTER-OF-PRESSURE SHIFT OF A BODY-WING-TAIL COMBINATION DUE TO ANGLE OF ATTACK AND MACH NUMBER AT TRANSONIC AND SUPERSONIC SPEEDS. J. Richard Spahr. May 1957. 43p. diagrs. (NACA TN 3966. Supersedes RM A55F02)

A theoretical investigation was made to determine the effects of systematic configuration changes on the center-of-pressure shift of an unbanked canard missile configuration having coplanar triangular-wing and -tail surfaces due to angle of attack and Mach number in the transonic and supersonic ranges. The following geometric variables were investigated independently of the others: ratio of wing semispan to tail semispan, ratio of body radius to wing semispan, ratio of tail length to body length, wing aspect ratio, tail aspect ratio, wing taper ratio, tail taper ratio, wing sweep, tail sweep, ratio of tail height to body radius, and wing-tail interdigitation.

NACA TN 3967

CHARACTERISTICS OF A 40° CONE FOR MEASURING MACH NUMBER, TOTAL PRESSURE, AND FLOW ANGLES AT SUPERSONIC SPEEDS. Frank J. Centolanzi. May 1957. 36p. diagrs. (NACA TN 3967)

An experimental investigation of the characteristics of a 40° cone for measuring Mach number, total pressure, and flow angles has been conducted. Data were taken for angles of pitch up to 26° at Mach numbers of 1.72, 1.95, and 2.46 for Reynolds numbers of 3.12 and 5.41 million per foot. This instrument is capable of measuring Mach number within approximately ±1.0 percent and the flow direction measured within ±0.25°. Charts are presented for the direct determination of these flow quantities.

NACA TN 3968

THE APPLICATION OF MATRIX METHODS TO COORDINATE TRANSFORMATIONS OCCURRING IN SYSTEMS STUDIES INVOLVING LARGE MOTIONS OF AIRCRAFT. Brian F. Doolin. May 1957. 36p. (NACA TN 3968)

The paper shows the method and advantages of matrix algebra in setting up geometric aspects of problems of airplane motion. Such aspects arise particularly in studies of systems which include aircraft. The paper first discusses the matrix properties needed. Then it applies them in several examples.

NACA TN 3969

A THEORETICAL STUDY OF THE EFFECT OF UPSTREAM TRANSPIRATION COOLING ON THE HEAT-TRANSFER AND SKIN-FRICTION CHARACTERISTICS OF A COMPRESSIBLE, LAMINAR BOUNDARY LAYER. Morris W. Rubesin and Mamoru Inouye. May 1957. 41p. diagrs., tab. (NACA TN 3969)

The present analysis considers a compressible, laminar boundary layer on a flat plate. The flat plate is divided into two regions: an upstream region of finite length which is porous and transpiration cooled with air, and a downstream region which is nonporous and is protected by the upstream cooling process.

NACA TN 3973

ORIGIN AND PREVENTION OF CRASH FIRES IN TURBOJET AIRCRAFT. I. Irving Pinkel, Solomon Weiss, G. Merritt Preston, and Gerard J. Pesman. May 1957. 65p. diagrs., photos., tab. (NACA TN 3973)

The manner in which the jet engine may start a crash fire was explored in test-stand and full-scale crash studies. On the basis of these studies, a method was devised for inerting and cooling the engine parts that may serve as ignition sources in crash. This method was tried successfully in full-scale crashes of jet-powered airplanes carrying engines in pod nacelles and engines buried within the airplane structure.

NACA TN 3975

INVESTIGATION OF A FULL-SCALE, CASCADE-TYPE THRUST REVERSER. Robert C. Kohl and Joseph S. Algranti. April 1957. 53p. diagrs., photos. (NACA TN 3975)

A double set of turning vanes was carried inside the jet tailpipe. To produce reverse thrust, the tailpipe opens into two side sections and the turning vanes move outward to form a V-shaped cascade, which deflects the exhaust-gas flow. Forward and reverse net thrust were measured over a range of engine speeds with the airplane stationary. Taxi tests were made to determine the comparative stopping distances using wheel braking and reverse thrust separately, and a combination of both. The effect of turning-vane spacing on thrust-reverser performance was determined by scale-model tests using unheated air.

CURRENT NACA RESEARCH REPORTS

NACA TN 3978

SURVEY OF THE ACOUSTIC NEAR FIELD OF THREE NOZZLES AT A PRESSURE RATIO OF 30. Harold R. Mull and John C. Erickson, Jr. April 1957. 32p. diagrs., photos. (NACA TN 3978)

The sound pressures radiating from the exhaust streams of two convergent-divergent and one convergent nozzle were measured. Exit diameters were 1.206 in. for the expanded nozzle and 0.625 in. for the convergent nozzle. The results are presented in a series of contour maps of overall and fine 1/3-octave-band sound pressures. The location of the source of the noise in each 1/3-octave band in the frequency range of 30 to 16,000 cps and the total power radiated were determined and compared with those of subsonic jets.

NACA TN 3979

EFFECT OF BLUNTNESS ON TRANSITION FOR A CONE AND A HOLLOW CYLINDER AT MACH 3.1. Paul F. Brinich and Norman Sands. May 1957. 42p. diagrs. (NACA TN 3979)

Bluntness was more effective in displacing transition downstream on a cylinder than on a cone. The downstream displacement of transition is related to the formation of a shock layer within which the Reynolds and Mach numbers are reduced and to pressure gradients that exist over the forward part of the model. Round bluntness in general had a favorable effect, whereas sharp-cornered flat bluntness above a certain size had unfavorable effects on the location of the transition point.

NACA TN 3980

INVESTIGATION OF SEMIVANELESS TURBINE STATOR DESIGNED TO PRODUCE AXIALLY SYMMETRICAL FREE-VORTEX FLOW. Harold E. Rohlik and William T. Wintucky. April 1957. 39p. diagrs., photos., tabs. (NACA TN 3980)

A semivaneless turbine stator designed to eliminate blade wakes and secondary-flow accumulations of boundary-layer air was built and tested. Performance of this stator was evaluated with static pressures measured in the vaneless section and surveys of total pressure and flow angle made at the stator exit. Results are presented in terms of theoretical and experimental velocities and flow angles, boundary-layer parameters, and contours of total-pressure loss across the stator.

NACA TN 3981

TABLES OF VARIOUS MACH NUMBER FUNCTIONS FOR SPECIFIC-HEAT RATIOS FROM 1.28 TO 1.38. Lewis Laboratory Computing Staff. April 1957. 76p. tabs. (NACA TN 3981)

Tables of Mach number functions are presented for a range of specific-heat ratios. The tables provide information supplemental to the notes and tables of Report 1135.

NACA TN 3982

EXPLORATORY STUDY OF GROUND PROXIMITY EFFECTS ON THRUST OF ANNULAR AND CIRCULAR NOZZLES. Uwe H. von Glahn. April 1957. 48p. diagrs., photos. (NACA TN 3982)

The proximity of the ground to an annular nozzle can result in thrust augmentation of up to 50 percent. The magnitude of thrust augmentation was a function of ground-to-nozzle distance, nozzle configuration, and nozzle pressure ratio. With a conventional circular nozzle a thrust reduction of 15 to 40 percent due to ground effect was obtained. The degree of thrust reduction was primarily a function of nozzle pressure ratio and ground-to-nozzle distance.

NACA TN 3993

BURSTING STRENGTH OF UNSTIFFENED PRESSURE CYLINDERS WITH SLITS. Roger W. Peters and Paul Kuhn. April 1957. 21p. diagrs., photos., tabs. (NACA TN 3993)

Internal-pressure tests were made on aluminum-alloy unstiffened cylinders with precut slits to study the effect of slit length and curvature on the hoop stress developed at the bursting pressure. The results are predicted with good accuracy by applying a curvature correction to the method presented in NACA TN 3816 for computing the strength of flat plates with cracks. In this investigation cylinders were pressurized with air and oil. The results indicate that the pressurizing medium has a negligible effect on the bursting pressure.

NACA TN 3997

A NOTE ON THE EFFECT OF HEAT TRANSFER ON PEAK PRESSURE RISE ASSOCIATED WITH SEPARATION OF TURBULENT BOUNDARY LAYER ON A BODY OF REVOLUTION (NACA RM-10) AT A MACH NUMBER OF 1.61. K. R. Czarnecki and Archibald R. Sinclair. April 1957. 13p. diagrs., photos. (NACA TN 3997)

The effects of heat transfer on the peak pressure rise associated with the separation of a turbulent boundary layer on a body of revolution (NACA RM-10) at a Mach number of 1.61 have been determined experimentally. Tests were made over a Reynolds number range, based on the distance from model nose to separation point, from 11.6×10^6 to 34.8×10^6 for a ratio of model-wall temperature to stagnation temperature of 0.96 (zero heat transfer) to 0.75. The results indicate little or no effect of heat transfer on the peak pressure rise for separation. The technique of using shock angles to determine the peak pressure rise for separation gave results that were in fairly good agreement with those obtained in previous investigations by means of measured pressures.

CURRENT NACA RESEARCH REPORTS

NACA TN 3998

GROUND SIMULATOR STUDIES OF THE EFFECTS OF VALVE FRICTION, STICK FRICTION, FLEXIBILITY, AND BACKLASH ON POWER CONTROL SYSTEM QUALITY. B. Porter Brown. April 1957. 45p. diagrs., photo. (NACA TN 3998)

Ground simulator tests were made to study the effects of various ratios of valve friction to stick friction on power control system quality. Boundaries are determined for good, tolerable, and unsatisfactory ranges of valve and stick friction for a rigid control system and a system with flexibility between the source of stick friction and the valve. The effect of various friction ratios with flexibility between the pilot and the source of stick friction is presented. The effect of backlash with various friction ratios is also presented.

NACA TN 4000

A PHENOMENOLOGICAL RELATION BETWEEN STRESS, STRAIN RATE, AND TEMPERATURE FOR METALS AT ELEVATED TEMPERATURES. Elbridge Z. Stowell. May 1957. 19p. diagrs., tab. (NACA TN 4000)

A phenomenological relation between stress, strain rate, and temperature is suggested to account for the behavior of polycrystalline metals above the equicohesive temperature. The properties of the metal included in the relation are elasticity, linear thermal expansion, and viscosity. The relation may be integrated under various conditions to provide information on creep rates, creep rupture, stress-strain curves, and rapid-heating curves. It is shown that for one material - 7075-T6 aluminum-alloy sheet - the information yielded by the relation for these four applications agrees reasonably well with test data.

NACA TN 4002

INTERACTION OF MOVING SHOCKS AND HOT LAYERS. Robert V. Hess. May 1957. 65p. diagrs. (NACA TN 4002)

Interactions are treated of normal and oblique shocks with hot layers at various temperatures. A brief discussion of spherical and cylindrical shocks is also given. Emphasis is on the fact that at very high temperatures the hot-layer shape undergoes drastic changes. The hot layer is forced to accumulate in a growing bubble-shaped region bound to the moving shock. If the cold flow over the bubble is subsonic, it may divide as it approaches the wall at the end of the bubble and cause a cold jet to penetrate under the bubble. A supersonic flow over the bubble can meet the wall with a shock. Under the influence of mixing, the hot-layer flow can no longer accumulate and a separation bubble is formed. It differs significantly from that in steady boundary layers since it is bound to the moving shock.

NACA TN 4010

EXPERIMENTALLY DETERMINED NATURAL VIBRATION MODES OF SOME CANTILEVER-WING FLUTTER MODELS BY USING AN ACCELERATION METHOD. Perry W. Hanson and W. J. Tuovila. April 1957. 46p. diagrs., photo., tab. (NACA TN 4010)

Three-dimensional views are presented of the first three natural vibration mode shapes of ten cantilever-wing models. A table of normalized deflections at six spanwise and five chordwise stations is included for each mode. These mode shapes were measured by a rather unique experimental technique using grains of sand as accelerometers. The technique, which is particularly suited for measuring mode shapes of small wing models, is described and some of the difficulties likely to be encountered in applying the technique are discussed.

National Gas Turbine Establishment (Gt. Brit.) TEMPERATURE EFFECTS IN A TURBO-JET ENGINE NOZZLE BLADE DURING TRANSIENT OPERATION. H. Taylor, R. E. Wilsdon, and M. R. Abbott. January 1957. 83p. diagrs., photos. NGTE R.191. (Ask for N-48514*)

Transient operation of a turbojet engine may result in the turbine blading being subjected to severe thermal stresses. An engine experiment showed that shutdown from full speed was the most severe case and subsequent work was directed to this problem. Calculations of blade temperature were made based on equilibrium heat-transfer data to assess a quasi-static approach to the transient temperature problem. Reasonable correlation was obtained between calculated results and the engine experiment.

A STUDY OF THE CORRELATION BETWEEN FLIGHT AND WIND-TUNNEL BUFFET LOADS. Wilber B. Huston. (Presented to Structures and Materials Panel, Advisory Group for Aeronautical Research and Development, Copenhagen, Denmark, April 29-May 4, 1957). 31p. diagrs.
(Ask for N-51482*)

Methods and concepts developed in the study of random processes are applied to the loads on an airplane wing in buffeting. The power spectrum and probability distribution of the buffet loads as measured by electrical wire resistance strain gages suggest that these loads can be considered as the linear response of a lightly damped single-degree-of-freedom system to a random input. Dimensional analysis and beam theory are employed to develop a relation between the buffet loads on an airplane in flight and the loads on a model in a wind tunnel. Flight and model results are compared for several different configurations.

Advisory Group for Aeronautical Research and Development. A METHOD FOR SOLVING DYNAMIC PROBLEMS OF MODERN TRANSONIC AND SUPERSONIC WINGS. Luigi Broglio, Ministero Difesa, Aeronautica, Roma. (Presented at 3rd meeting of Structures & Materials Panel, AGARD, Washington, D. C., April 10-17, 1956). April 1956. 25p. diagrs. AGARD Report 38.
(Ask for N-51811*)

Presents a method for the general solution of dynamic problems of delta, swept, or crescent wings, or those of a more general type. The first part gives a method for the determination of frequencies and modes of vibration, with the influence coefficients and mass distribution assumed known. In the second part the calculation of the influence functions is discussed and, in the third, the methods of the previous two parts are applied to practical problems. The appendix shows how to determine the influence functions in specific simplified cases.

Advisory Group for Aeronautical Research and Development. NEEDED RESEARCH FOR MACHINE INFORMATION SYSTEMS. John W. Kuipers, Eastman Kodak Co. (Presented at 6th meeting of Documentation Committee, AGARD, Rome, February 20-25, 1956). February 1956. 18p. diagrs. AGARD Report 47.
(Ask for N-51812*)

Explains the difficulties which have arisen in using machines for documentation purposes and analyzes their causes. Emphasizes the need for research on the nature of the units to be handled and indicates lines along which research should be directed to overcome these difficulties.

N-51813*

Advisory Group for Aeronautical Research and Development. OPERATIONAL PROBLEMS REQUIRING DOCUMENTATION RESEARCH. Verner W. Clapp, Library of Congress. (Presented at 6th meeting of Documentation Committee, AGARD, Rome, February 20-25, 1956). February 1956. 7p. AGARD Report 48. (Ask for N-51813*)

The operations involved in documentation are so interrelated as to form a seamless whole: the form of the document affects the manner of its treatment and storage, and these in turn affect the retrieval of the information contained in it and the creation of new documents. No part of the cycle may, in consequence, be taken in isolation or for granted - least of all the "information-gathering habits" of intellectual workers, because these assume existing methods of documentation. Similarly, most documentation enterprises involve special activity in one or more parts of the cycle while assuming stability of the other parts, and since such enterprises are under pressure to serve the immediate needs of particular constituencies, no one has a broad assignment for criticism and experimental improvement with respect to the whole cycle. Some suggestions are made with respect to this situation.

Advisory Group for Aeronautical Research and Development. THE PROBLEMS OF VISION IN FLIGHT AT HIGH ALTITUDE. Thomas C. D. Whiteside, U. of Glasgow and Royal Air Force Institute of Aviation Medicine. 1957. 162p. diagrs., photos., tabs., discussion. AGARDograph 13.

This study refers to flight in the stratosphere or upper limits of the troposphere above the clouds. Observations were made at about 40,000 feet, but the findings can also be applied to flight outside the earth's atmosphere. Generally the problems dealt with were not an effect of speed, so the findings are applicable to balloons, civil transports, or high performance fighters. The subjects studied included the effects of changes in intensity and spectral distribution of sunlight, physiological changes affecting visibility of objects inside the cockpit, and physiological factors affecting air-to-air visibility.

FLIGHT LOADS MEASUREMENTS ON NACA RESEARCH AIRPLANES. De E. Beeler. (Presented to Structures and Materials Panel, Advisory Group for Aeronautical Research and Development, Copenhagen, Denmark, April 29 - May 4, 1957). 36p. diagrs., photos. (Ask for N-51987*)

Summarizes results from flight loads investigations conducted primarily for the purpose of confirming wind-tunnel results by comparing the full-scale results with comparable wind-tunnel results. Generally, the data have been selected from three research aircraft having a wide range of configuration (X-1, X-5, and XF-92A). Flight loads for the various components of these aircraft were determined by use of calibrated strain gages. Pressure distribution measurements were also made of the fuselage and the wing of the X-1 airplane.

Advisory Group for Aeronautical Research and Development. FLUCTUATIONS AND HOT-WIRE ANEMOMETRY IN COMPRESSIBLE FLOWS. Mark V. Morkovin, Johns Hopkins University. November 1956. (xiv), 102p. diagrs., tabs. AGARDograph 24.
(Ask for N-53172*)

The problem of extracting information from a heated thin wire cooled by an unsteady compressible flow is treated. Empirical evidence on heat transfer from thin wires at high speeds is analyzed. Procedure for the different speed ranges is outlined and probable accuracy discussed. Parallel procedures for mean-flow measurements are also given.

THREE-DIMENSIONAL LAMINAR SEPARATION. (Le Decollement Laminaire En Trois Dimensions). E. A. Eichelbrenner and A. Oudart. November 1956. 11p. diagr., photos., tab. Translation from Recherche Aeronautique, no. 47, p. 11-14, September - October 1955. (Ask for N-41489*)

A three-dimensional definition leads to a new interpretation of laminar separation which coincides with the customary picture in particular cases (three-dimensional separation, separation generatrix of an infinite cylinder in sideslip). This new definition has been confirmed by tests performed in the hydrodynamic tunnel at Chatillon.

N-43015*

THE FLOW PATTERN AROUND A ROTATING DISK IN AN AIRSTREAM. (Die Strömung an einer angeblasenen rotierenden Scheibe). H. Schlichting and E. Truckenbrodt. April 1957. 33p. diagrs., tabs. Translation from Zeitschrift für angewandte Mathematik und Mechanik, v. 32, no. 4/5, Apr./May 1952, p. 97-111. (Ask for N-43015*)

The laminar flow about a rotating plane disk which is simultaneously approached by an airstream in the direction of the axis of rotation is computed. The thickness of the layer carried along by the rotational motion, and therefore the torque, are strongly dependent on the ratio of the free-stream velocity and the peripheral velocity of the disk.

FABRICATION OF MODELS WITH THE AID OF PLASTIC MATERIALS. (Fabrication de maquettes à l'aide des matières plastiques). G. Dixmier. March 1957. 45p. photos. Translation of Office National d'Etudes et de Recherches Aeronautiques Note Technique 33. (Ask for N-43153*)

Shows examples of the fabrication of models which illustrate the use that can be made of low-pressure polymerizable resins in conjunction with glass cloth in the testing technique of experimental aerodynamics.

N-43469*

FLOW AHEAD OF A SUPERSONIC ROTOR. (Strömung vor einem Überschall-Laufrad). H. Söhngen. January 1957. 19p. diagrs. Translation from Deutsche Versuchsanstalt für Luftfahrt E.V., Mülheim/Ruhr, Report 11, December 1955, p. 1-23. (Ask for N-43469*)

We consider a supersonic axial compressor; the blades of the rotor are in a supersonic flow. In the designs which are of chief interest at present, the axial component of the flow velocity lies below the speed of sound; in contrast, the rotational velocity of the rotor is large. We shall limit ourselves to this case. In order to eliminate the difficult question of interference between stator and rotor, we shall further assume that no stator is present, that therefore the rotor alone operates in the annular channel. In order to avoid the difficulties introduced by the radical extension of the blades, we shall finally assume that the height of the blades is small compared to the diameter of the blade rim. The flow process about the blades can then be developed into a plane.

PROPAGATION OF SOUND IN THE ATMOSPHERE AND AUDIBILITY OF ALARM SIGNALS IN SURROUNDING NOISE. (Propagation du Son dans l'Atmosphere et Audibilite des Signaux Avertisseurs dans le Bruit Ambiant). Paul Baron. October 1956. 46p. diagrs., photos. Translation from Groupement des Acousticieus de Langue Francaise, Cahiers d'Acoustique 66, 1954. (Ask for N-45453*)

In the introduction, the author recalls the origin of this study which is quite old but of renewed interest today. He defines the general conditions of the propagation of sound in the atmosphere. He describes the various series of tests performed in the Yonne valley, specifying the character of the region, the sound sources, the devices for measuring the sound pressure, the meteorological measuring devices, the organization of the tests, and the results obtained (variation of the signal received, influence of the height above the ground of the source, of the topographical situation, etc.) in Paris. He then studies the influence of the wind on the propagation of sound, by its direction, by its velocity, and the influence of factors other than the wind. He gives the conditions of audibility of the signals in the presence of noises; and determines the range of the sound sources.

N-51921*

APPLICATION OF THE DISTRIBUTION THEORY TO THE PROBLEM OF THE SUPERSONIC AIRFOIL. (Anwendung der Distributionstheorie auf das Problem des Überschall-Traglügels). R. Sauer. January 1957. 24p. diagrs. Translation from Ministère de l'Air. Publications Scientifiques et Techniques, 1954, p. 289-308. (Ask for N-51921*)

Schwartz's distribution theory is applied to initial- and boundary-value problems of the wave equation, namely to the calculation of the linearized three-dimensional steady supersonic flow about an airfoil of finite width. The fundamental representation formulas of airfoil theory result in a very simple manner, since the difficulties arising in the ordinary analysis due to divergent integrals are eliminated in the distribution theory, because of the enlarged concept of functions. We begin with a short introduction into the distribution theory and develop the fundamental concepts of distribution theory as graphically as possible.

DIFFERENTIAL EQUATIONS OF MOTION CONTAINING A SLOWNESS PARAMETER. (Differentsialnye uravneniya dvizheniya coderzhashchie parametr medlennosti). V. M. Volosov. (1957). 6p. Translation from Akademiia Nauk SSSR, Doklady, v.106, no.1, p.7-10, 1956. (Ask for N-51948*)

The problem of second-order differential equations is considered wherein the slowness of the change in the analogous factors of mass, damping, and spring is characterized by a small slowness parameter appearing as a multiplier of the independent variable, time. The small parameter is also a multiplier of the damping, or friction, term. Several special cases are considered as examples, and some general mathematical formulations are given for the determination of regions of oscillatory solutions.

SUBSTITUTES FOR WIND-TUNNEL MEASUREMENTS, WITH SPECIAL CONSIDERATION OF FREE-FLIGHT MEASUREMENTS. (Ersatz für Windkanalmessungen, bei besonderer Berücksichtigung von Messungen im freien Fluge). Wilhelm Neuberger. December 1956. 69p. diagrs., tabs. Translation from Zeitschrift für Flugwissenshaften, v.3, no.7, July 1955. (Ask for N-51950*)

In the present paper, possibilities and indications for a future development regarding the problem of replacing large and expensive wind tunnels by other more simple methods are discussed. Intensive research and development work in various fields will be necessary before a complete and practical method will be available. Great interest is focused on a method in which the aerodynamic force is determined indirectly from the motion of a rigid body of arbitrary shape in free air.

N-53001*

THE TEST FACILITIES USED FOR THE FLYING ATAR. (Les Installations d'Essais Mises en Oeuvre pout l'ATAR volant). G. Eggers and J. Jardinier. (Presented at 6th meeting of AGARD, Brussels, August 29, 1956). December 1956. 24p. photos. Translation from Societé Nationale d'Etude et de Construction de Moteurs d'Aviation. (Ask for N-53001*)

The special problems involved in vertical take-off and landing have been studied and experimented on separately. After this preliminary period, the S.N.E.C.M.A. has built a device called the "Flying ATAR" which has proved that the system chosen operates well. This engine assembly, equipped with its controls and its stabilization system, lends itself to the construction of an airplane of any aerodynamic conception which can take off vertically.

NACA RM A9E09

AERODYNAMIC STUDY OF A WING-FUSELAGE COMBINATION EMPLOYING A WING SWEPT BACK 63°.- CHARACTERISTICS FOR SYMMETRICAL WING SECTIONS AT HIGH SUBSONIC AND MODERATE SUPERSONIC MACH NUMBERS. Newton A. Mas. July 7, 1949. 28p. diagrs., photos. (NACA RM A9E09)

Results of wind-tunnel tests are presented for a wing with the leading edge swept back 63° and of symmetrical section in combination with a body at Mach numbers from 0.5 to 0.95 and from 1.09 to 1.51. The measured variations with Mach number of lift, drag, and pitching-moment coefficients are compared with calculated variations and the results of higher-scale investigations.

NACA RM A50A23

WIND-TUNNEL INVESTIGATION AT LOW SPEED OF A WING SWEPT BACK 63° AND TWISTED AND CAMBERED FOR A UNIFORM LOAD AT A LIFT COEFFICIENT OF 0.5. James A. Weiberg and Hubert C. Carel. May 9, 1950. 53p. diagrs., photos., tabs. (NACA RM A50A23)

Results are presented of force and pressure-distribution measurements at low speed on a semi-span model of a wing with the leading edge swept back 63° and with the wing cambered and twisted for uniform load at a lift coefficient of 0.5 and at a Mach number of 1.4. Compared with a thicker flat wing of the same plan form, the twisted and cambered wing showed no improvement in longitudinal-stability characteristics. Spanwise boundary-layer flow and separation resulted in large stability changes with angle of attack. By adding flaps and fences to the wing these separation effects were delayed to higher angles of attack. Good agreement was obtained between the measured span load distribution and that computed by methods of Weissinger.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A53E21

INVESTIGATION OF THE USE OF A STICK FORCE PROPORTIONAL TO PITCHING ACCELERATION FOR NORMAL-ACCELERATION WARNING. Marvin Abramovitz, Stanley F. Schmidt, and Rudolph D. Van Dyke, Jr. August 1953. 23p. diagrs., tab. (NACA RM A53E21)

The feasibility of providing an additional stick force which leads the normal acceleration, in order to serve as a prior warning of excessive normal acceleration in rapid maneuvers, is investigated both experimentally in flight and analytically. It is determined that large stick forces proportional to rate of change of normal acceleration can be provided without adversely affecting the control-system dynamic stability, and that pilots consider the feel characteristics introduced by such a force to be very desirable.

NACA RM A53E28

EXPERIMENTAL INVESTIGATION OF THE EFFECT OF ENTRANCE WIDTH-TO-HEIGHT RATIO ON THE PERFORMANCE OF AN AUXILIARY SCOOP-TYPE INLET AT MACH NUMBERS FROM 0 TO 1.3. George B. Brajnikoff and John F. Stroud. July 1953. 16p. diagrs., photos. (NACA RM A53E28)

As a part of an investigation of variable-area auxiliary inlets intended to provide for the variation of engine air requirements with speed and altitude, three auxiliary scoop inlets were tested in combination with a nose inlet at Mach numbers from 0 to 1.3 at zero angle of attack. The pressure recovery and mass-flow characteristics are presented for these three models with auxiliary-inlet areas of 12 percent of the main-inlet area. The effects of the ratio of scoop width to height, lip alinement, and lip shape are discussed.

NACA RM A55E04

GROUND EFFECTS ON THE LONGITUDINAL CHARACTERISTICS OF TWO MODELS WITH WINGS HAVING LOW ASPECT RATIO AND POINTED TIPS. Donald A. Buell and Bruce E. Tinling. July 1955. 48p. diagrs., photos., tabs. (NACA RM A55E04)

Wind-tunnel tests were conducted to determine the ground effects on a tailless model with a wing of aspect ratio 2 and infinite taper, and on a tailed model with a triangular wing of aspect ratio 3, with flaps. Control-surface hinge moments were measured on the tailless model. The results are compared with the predictions of the theory of Tani, et al.

NACA RM E51E04

INVESTIGATION OF INTERNAL FILM COOLING OF 1000-POUND-THRUST LIQUID-AMMONIA - LIQUID-OXYGEN ROCKET-ENGINE COMBUSTION CHAMBER. Gerald Morrell. July 1951. 42p. diagrs., photos., tabs. (NACA RM E51E04)

Internal film cooling of the combustion chamber of a 1000-pound-thrust liquid ammonia - liquid oxygen rocket engine was investigated at chamber pressures ranging from 220 to 270 pounds per square inch absolute and coolant flows from 2 to 21 percent of total flow. The three coolants investigated were water, ethyl alcohol, and liquid ammonia. The fuels were found to be satisfactory film coolants in the absence of simultaneous regenerative cooling and data were presented for estimating film-cooling requirements of rocket-engine chambers.

NACA RM E51E29

DATA PRESENTATION OF FORCE CHARACTERISTICS OF SEVERAL ENGINE-STRUT-BODY CONFIGURATIONS AT MACH NUMBERS OF 1.8 AND 2.0. Robert T. Madden and Emil J. Kremzier. August 1951. 32p. diagrs. (NACA RM E51E29)

Investigation to determine lift, drag, and pitching-moment characteristics of several engine-strut-body combinations was conducted over range of angles of attack from 0° to 10° at Mach numbers of 1.8 and 2.0. The average Reynolds number based on body length was 28×10^{6}. Data are presented without analysis and indicate decreases in minimum drag and lift curve slope with decreasing strut length. Decreases in minimum drag were also noted with rearward movement of engines.

NACA RM E52E01

AN ANALYSIS OF THE POTENTIALITIES OF A TWO-STAGE COUNTERROTATING SUPERSONIC COMPRESSOR. Ward W. Wilcox. July 1952. 41p. diagrs., tab. (NACA RM E52E01)

Evaluation of the potentialities of a two-stage counterrotating supersonic compressor was made by using one-dimensional analysis to indicate magnitude of major design variables at various pressure ratio levels. Results of simplified three-dimensional design study for pressure ratio of 8 are presented to demonstrate similarities to and differences from one-dimensional analysis. Comparison of component performance of two compressor stages recently investigated with analytical requirements for pressure ratio of 5 indicated that a counterrotating compressor with the following characteristics might be constructed: weight flow, 30 pounds per second per square foot frontal area, pressure ratio 5, tip speed 1100 feet per second, adiabatic efficiency 0.80 or higher. If weight penalty resulting from mechanical details of coaxial shafting were not too severe, a distinct advantage in engine size would be possible.

NACA RM E53B10

DETERMINATION OF SURGE AND STALL LIMITS OF AN AXIAL-FLOW TURBOJET ENGINE FOR CONTROL APPLICATIONS. Ross D. Schmidt, George Vasu, and Edward W. McGraw. August 1953. 30p. diagrs., tab. (NACA RM E53B10)

Limitations on the transient operation of an axial-flow turbojet engine were determined in relation to altitude and exhaust-nozzle-area parameters. A high-frequency oscillation (stall) at the compressor inlet limited transient operation of the engine below approximately 70 percent of the generalized engine rotational speed. Over 70 percent of the engine-speed transient operation was limited by a low-frequency oscillation (surge) which occurred throughout the engine. The data presented are the result of an analysis of oscillograph traces obtained when the engine was operated off steady state by introducing either a step increase or a ramp increase in fuel flow. For a given speed, a lower fuel flow was required for the engine to recover from surge or stall than was necessary for surge or stall to occur. Very little difference existed between the surge line (compressor pressure ratio against engine rotational speed) obtained under transient conditions and that obtained under steady-state conditions by decreasing the flow area with an adjustable first-stage turbine stator.

NACA RM E55E11

REMOVAL OF SECONDARY-FLOW ACCUMULATIONS IN A TWO-DIMENSIONAL TURBINE NOZZLE PASSAGE BY BOUNDARY-LAYER BLEED. Robert Y. Wong. June 1955. 22p. diagrs., photos., tab. (NACA RM E55E11)

The results of this investigation indicate that boundary-layer bleed along the juncture of the passage suction surface and end wall may be effectively used to prevent the local accumulation of boundary-layer fluids due to secondary flows in a single-passage nozzle. Bleed-slot geometry and position and bleed pressure were found to markedly influence bleed weight flow and bleed-slot effectiveness. Boundary-layer bleed applied in this manner to a turbine stator thus offers a means of investigating the effect of these loss regions on turbine rotor performance. Bleed weight flow required for an annular cascade remains to be determined.

NACA RM E56B10

ANALYSIS OF A FORM OF PEAK HOLDING CONTROL. G. J. Delio. March 1956. 57p. diagrs. (NACA RM E56B10)

A typical plant process possessing sudden drops and inert zones in its output was studied. The output was subjected to harmonic analysis to determine signal possibilities and the results were used in the design of a control. The particular form of peak holding control used, being only one of the possible forms, was studied for various performance criteria. It was found that a stable control of the type investigated was realizable and the average output could be maintained near the peak output value.

NACA RM L8E25

FREE-FLIGHT INVESTIGATION AT TRANSONIC AND SUPERSONIC SPEEDS OF THE ROLLING EFFECTIVENESS OF A 42.7° SWEPTBACK WING HAVING PARTIAL-SPAN AILERONS. Carl A. Sandahl. October 25, 1948. 13p. diagrs., photo., tab. (NACA RM L8E25)

An investigation of the rolling effectiveness at transonic and supersonic speeds of partial-span ailerons on a 42.7° sweptback wing having symmetrical circular-arc airfoil sections of 10-percent thickness ratio normal to the wing quarter-chord line has been made by means of rocket-propelled test vehicles. The results are compared with results of a supersonic wind-tunnel test at Mach number 1.9.

NACA RM L8E28

FREE-FLIGHT INVESTIGATION AT TRANSONIC AND SUPERSONIC SPEEDS OF A WING-AILERON CONFIGURATION SIMULATING THE D-558-2 AIRPLANE. Carl A. Sandahl. July 21, 1948. 10p. diagrs., photo., tab. (NACA RM L8E28)

An investigation of the rolling effectiveness at transonic and supersonic speeds of a wing-aileron configuration simulating the D-558-2 airplane has been made by means of a rocket-propelled test vehicle. The variation of rolling effectiveness with Mach number is similar to that obtained previously for tapered sweptback wings having full-span, 0.2-chord ailerons.

NACA RM L8H09

FLIGHT AND WIND-TUNNEL INVESTIGATION TO DETERMINE THE AILERON-VIBRATION CHARACTERISTICS OF 1/4-SCALE WING PANELS OF THE DOUGLAS D-558-2 RESEARCH AIRPLANE. Ellwyn E. Angle and Reginald R. Lundstrom. November 30, 1948. 27p. diagrs., photos., tabs. (NACA RM L8H09)

Report contains results of flight and wind-tunnel tests to determine the vibration characteristics of 1/4-scale dynamically similar ailerons for the D-558-2 research airplane. On one flight no vibrations occurred up to a Mach number of 1.03. On a second flight an oscillation developed believed to be flexure-aileron flutter from a Mach number of 0.58 up to a Mach number of 0.73 and aileron "buzz" above a Mach number of 0.96. Wind-tunnel tests confirmed that the vibration between a Mach number of 0.58 and 0.70 was flexure-aileron flutter.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L8K19a

AN INVESTIGATION OF THE SPIN AND RECOVERY CHARACTERISTICS OF A 1/25-SCALE MODEL OF THE DOUGLAS D-558-II AIRPLANE. Stanley H. Scher and Lawrence J. Gale. January 18, 1949. 29p. diagrs., photos., tabs. (NACA RM L8K19a)

An investigation has been conducted on a 1/25-scale model of the Douglas D-558-II airplane in the Langley 20-foot free-spinning tunnel. The effects of control disposition and movement upon the erect and inverted spins and recoveries have been determined for the normal design gross weight loading. The spin-recovery parachute requirements and the effect of varying the stabilizer incidence, of extending the slats, and of removing the stall-control vanes were also investigated. The results of the investigation indicated that the recovery characteristics of the airplane may be unsatisfactory and that installation of a large ventral fin would cause recoveries to be satisfactory.

NACA RM L9A06

FLIGHT INVESTIGATION OF FLUTTER MODELS WITH 1/10-SCALE DOUGLAS D-558-2 WING PANELS. Jerome M. Teitelbaum. February 16, 1949. 15p. diagrs., photos., tab. (NACA RM L9A06)

Contains the results of flight tests on three models containing scaled versions of the D-558-2 wing panels as horizontal fins. Results indicate that no flexure-torsion flutter occurred during the flights but a pitching oscillation of the entire model developed as the model passed through the transonic range.

NACA RM L9A24

ANALYSIS OF THE EFFECTS OF VARIOUS MASS, AERODYNAMIC, AND DIMENSIONAL PARAMETERS ON THE DYNAMIC LATERAL STABILITY OF THE DOUGLAS D-558-2 AIRPLANE. M. J. Queijo and W. H. Michael, Jr. April 15, 1949. 33p. diagrs., tabs. (NACA RM L9A24)

The effects of various mass, aerodynamic, and dimensional parameters on the dynamic lateral stability of the Douglas D-558-2 airplane have been investigated by means of calculations of the stability boundaries and the period and damping of the lateral oscillation. The results indicate that accurate determination of the stability derivatives, the radii of gyration, and the inclination of the principal axes are required if calculations of the dynamic lateral stability are to be of quantitative significance. Variations in the magnitudes of these quantities that might correspond to errors resulting from casual estimates may be very important.

NACA RM L9C04

HIGH-SPEED WIND-TUNNEL INVESTIGATION OF THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 1/16-SCALE MODEL OF THE D-558-2 RESEARCH AIRPLANE AT HIGH SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. Robert S. Osborne. April 5, 1949. 87p. diagrs., photos., tabs. (NACA RM L9C04)

A 1/16-scale model of the D-558-2 was tested to determine its force, longitudinal stability, and control characteristics at Mach numbers from 0.6 to 0.95 and at a Mach number of 1.2. The effects of chordwise fences on the force and moment characteristics of the model are also presented.

NACA RM L9E20a

EFFECTS OF CERTAIN FLOW NONUNIFORMITIES ON LIFT, DRAG, AND PITCHING MOMENT FOR A TRANSONIC-AIRPLANE MODEL INVESTIGATED AT A MACH NUMBER OF 1.2 IN A NOZZLE OF CIRCULAR CROSS SECTION. Virgil S. Ritchie. August 31, 1949. 12p. diagrs., photo. (NACA RM L9E20a)

Investigation of a model of a transonic airplane at Mach number 1.2 in the Langley 8-foot high-speed tunnel showed no significant changes in model lift, drag, and pitching-moment coefficients for various axial locations of a given flow nonuniformity along the length of the model. The stream normal shock produced no appreciable force changes for the sting-supported model as long as the shock was located entirely downstream of the model base and tail surfaces.

NACA RM L9E27a

A PRESSURE-DISTRIBUTION INVESTIGATION OF A SUPERSONIC AIRCRAFT FUSELAGE AND CALIBRATION OF THE MACH NUMBER 1.59 NOZZLE OF THE LANGLEY 4- BY 4-FOOT SUPERSONIC TUNNEL. Morton Cooper, Norman F. Smith, and Julian H. Kainer. July 29, 1949. 51p. diagrs., photos., tabs. (NACA RM L9E27a)

Experimental pressure distributions have been obtained on a supersonic-aircraft fuselage with and without canopies (body of revolution) in the Langley 4- by 4-foot supersonic tunnel at a Mach number of 1.59 and a Reynolds number of 2.60×10^6. A comparison of the experimental pressures with theoretical pressures for the body of revolution is presented in addition to the experimental pressures over the fuselage with canopies. Calibration data of the test section are also presented.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L9G18

PRELIMINARY MEASUREMENTS OF THE DYNAMIC LATERAL STABILITY CHARACTERISTICS OF THE DOUGLAS D-558-II (BUAERO NO. 37974) AIRPLANE. Sigurd A. Sjoberg. August 18, 1949. 8p. diagrs., tab. (NACA RM L9G18)

This paper presents some data on the dynamic lateral stability characteristics of the Douglas D-558-II (BuAero No. 37974) airplane. For the airplane in the clean condition, the lateral oscillations are lightly damped. In the landing condition, the airplane performs a constant-amplitude lateral oscillation.

NACA RM L9H31a

PRELIMINARY FLIGHT MEASUREMENTS OF THE STATIC LONGITUDINAL STABILITY AND STALLING CHARACTERISTICS OF THE DOUGLAS D-558-II RESEARCH AIRPLANE (BUAERO. NO. 37974). S. A. Sjoberg and R. A. Champine. October 18, 1949. 16p. diagrs., photos., tab. (NACA RM L9H31a)

Contains results of brief flight measurements of the static longitudinal stability and stalling characteristics of the Douglas D-558-II (BuAero. No. 37974) research airplane.

NACA RM L9L22

LONGITUDINAL TRIM AND DRAG CHARACTERISTICS OF ROCKET-PROPELLED MODELS REPRESENTING TWO AIRPLANE CONFIGURATIONS. James H. Parks and Jesse L. Mitchell. February 6, 1950. 25p. diagrs., photos., tab. (NACA RM L9L22)

The longitudinal trim and drag characteristics of two airplane configurations of a rocket-propelled model are presented. One configuration employed a thin straight wing and tail and the other had a thicker sweptback wing and tail. The basic data obtained were the variation of normal acceleration and Mach number with time at a series of fixed stabilizer incidences and center-of-gravity locations.

NACA RM L50C14

FLIGHT MEASUREMENTS WITH THE DOUGLAS D-558-II (BUAERO NO. 37974) RESEARCH AIRPLANE. STATIC LATERAL AND DIRECTIONAL STABILITY CHARACTERISTICS AS MEASURED IN SIDESLIPS AT MACH NUMBERS UP TO 0.87. S. A. Sjoberg. May 19, 1950. 29p. diagrs., photos., tab. (NACA RM L50C14)

The paper presents flight measurements during sideslips of the static lateral and directional stability characteristics of the Douglas D-558-II (BuAero No. 37974) research airplane. Data are presented for the Mach number range from 0.27 to 0.87.

NACA RM L50E16

SOME EFFECTS OF CHORDWISE FENCES ON THE AERODYNAMIC CHARACTERISTICS OF FOUR MODERATELY SWEPTBACK WINGS IN THE LOW-LIFT RANGE AT TRANSONIC MACH NUMBERS AND AT MACH NUMBER 1.9. Lawrence D. Guy. July 21, 1950. 22p. diagrs., photo., tab. (NACA RM L50E16)

A study of data from available wind-tunnel investigations has been made to determine the effects of several chordwise fences on some of the aerodynamic characteristics of moderately sweptback wings in the low-lift range at transonic Mach numbers and at Mach number 1.9. The wings were equipped with upper-surface fences of comparable size having a height above the wing-chord plane of less than 14 percent of the local chord. The data from tests of a small leading-edge vane and a triangular fin on one wing are also included.

NACA RM L50E17

FLIGHT MEASUREMENTS WITH THE DOUGLAS D-558-II (BUAERO NO. 37974) RESEARCH AIRPLANE. LATERAL CONTROL CHARACTERISTICS AS MEASURED IN ABRUPT AILERON ROLLS AT MACH NUMBERS UP TO 0.86. J. V. Wilmerding, W. H. Stillwell, and S. A. Sjoberg. July 20, 1950. 27p. diagrs., photos., tab. (NACA RM L50E17)

The paper presents flight measurements of the lateral control characteristics of the Douglas D-558-II (BuAero No. 37974) airplane as measured in abrupt rudder-fixed aileron rolls. Data are presented for a Mach number range from 0.25 to 0.86.

NACA RM L50E31

FLIGHT MEASUREMENTS WITH THE DOUGLAS D-558-II (BUAERO NO. 37974) RESEARCH AIRPLANE. MEASUREMENTS OF THE BUFFET BOUNDARY AND PEAK AIRPLANE NORMAL-FORCE COEFFICIENTS AT MACH NUMBERS UP TO 0.90. John P. Mayer and George M. Valentine. August 28, 1950. 31p. diagrs., photos., tab. (NACA RM L50E31)

The airplane buffet boundary and highest normal-force coefficients obtained in flight are presented for the Mach number range from 0.26 to 0.90.

NACA RM L50G10

FLIGHT MEASUREMENTS WITH THE DOUGLAS D-558-II (BUAERO NO. 37974) RESEARCH AIRPLANE. LOW-SPEED STALLING AND LIFT CHARACTERISTICS. W. H. Stillwell, J. V. Wilmerding, and R. A. Champine. September 5, 1950. 45p. diagrs., photos., tab. (NACA RM L50G10)

The paper presents the results of flight measurements of the low-speed stalling and lift characteristics of the Douglas D-558-II (BuAero No. 37974) research airplane. Data are presented for four different combinations of slat and flap settings.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L50H16a

CALCULATIONS OF THE DYNAMIC LATERAL STABILITY CHARACTERISTICS OF THE DOUGLAS D-558-II AIRPLANE IN HIGH-SPEED FLIGHT FOR VARIOUS WING LOADINGS AND ALTITUDES. M. J. Queijo and Alex Goodman. October 3, 1950. 31p. diagrs., tabs. (NACA RM L50H16a)

The dynamic lateral stability characteristics of the Douglas D-558-II airplane in high-speed flight were investigated by means of calculation of the period and rate of damping of the lateral oscillation. The aerodynamic derivatives used in the investigation were based on values measured at low speeds on a 0.13-scale model of the Douglas D-558-II. The effects of principal-axes inclination, wing loading, altitude, and Mach number were investigated.

NACA RM L50K13

FLIGHT MEASUREMENTS WITH THE DOUGLAS D-558-II (BUAERO NO. 37974) RESEARCH AIRPLANE. STATIC LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS AT MACH NUMBERS UP TO 0.87. S. A. Sjoberg, James R. Peele, and John H. Griffith. January 17, 1951. 48p. diagrs., photos., tab. (NACA RM L50K13)

The paper presents the results of flight measurements of the longitudinal stability and control characteristics of the Douglas D-558-II research airplane. Data are presented in the speed range from the stalling speed of the airplane up to a maximum Mach number of 0.87.

NACA RM L51C23

FLIGHT MEASUREMENTS WITH THE DOUGLAS D-558-II (BUAERO NO. 37974) RESEARCH AIRPLANE. DYNAMIC LATERAL STABILITY. W. H. Stillwell and J. V. Wilmerding. June 18, 1951. 36p. diagrs., photos., tabs. (NACA RM L51C23)

The paper presents flight measurements of the dynamic lateral stability of the D-558-II (BuAero No. 37974) research airplane. Data are presented for a range of calibrated airspeed from 167 miles per hour to 474 miles per hour.

NACA RM L51E08

LIFT AND DRAG COEFFICIENTS FOR THE BELL X-1 AIRPLANE (8-PERCENT-THICK WING) IN POWER-OFF TRANSONIC FLIGHT. L. Robert Carman and John R. Carden. June 1951. 24p. diagrs., photo., tab. (NACA RM L51E08)

Drag coefficients have been determined by the accelerometer method for the Bell X-1 airplane with 8-percent-thick wing and 6-percent-thick tail in power-off flight over a Mach number range of 0.64 to 1.14 and at lift coefficients from 0.1 to 1.2.

NACA RM L51E11

INVESTIGATION OF MINIMUM DRAG AND MAXIMUM LIFT-DRAG RATIOS OF SEVERAL WING-BODY COMBINATIONS INCLUDING A CAMBERED TRIANGULAR WING AT LOW REYNOLDS NUMBERS AND AT SUPERSONIC SPEEDS. Clinton E. Brown and L. K. Hargrave. August 1951. 62p. diagrs., photos., tabs. (NACA RM L51E11)

Theoretical and experimental results of the minimum drag and maximum lift-drag ratio of several wing-body combinations with wings of triangular, arrow, and diamond plan form are presented for $M = 1.62$, 1.93, and 2.41 and Reynolds number range of 1.4×10^6 to 0.7×10^6. Also included are two each of triangular and arrow plan-form wings cambered for approximately uniform load at $M = 1.62$ and lift coefficients of 0.08 and 0.20. Also included are liquid-film studies of the flow over the various configurations.

NACA RM L51E25

FLIGHT INVESTIGATION OF THE DRAG OF ROUND-NOSED BODIES OF REVOLUTION AT MACH NUMBERS FROM 0.6 TO 1.5 USING ROCKET-PROPELLED TEST VEHICLES. Roger G. Hart. July 1951. 9p. diagrs., photos., tab. (NACA RM L51E25)

Values of total drag coefficient were measured for four round-nosed bodies of revolution in free flight at Mach numbers from 0.6 to 1.5 and Reynolds numbers from 10×10^6 to 50×10^6. The bodies were designed by rounding off the sharp, fineness-ratio-3.56 nose of a previously tested configuration. The nose radii tested were 27.4, 38.7, 80.6, and 100 percent of the maximum body radius.

NACA RM L52C25

EFFECTS OF CHORD DISCONTINUITIES AND CHORDWISE FENCES ON LOW-SPEED STATIC LONGITUDINAL STABILITY OF AN AIRPLANE MODEL HAVING A 35° SWEPTBACK WING. Byron M. Jaquet. June 1952. 54p. photos., diagrs., tab. (NACA RM L52C25)

Results are presented for a low-speed investigation to determine effects of chord discontinuities and chordwise fences on static longitudinal stability characteristics of a 35° sweptback-wing model. Included are wake surveys, surface-tuft photographs, and tuft-grid photographs.

NACA RM L52E02

LONGITUDINAL FREQUENCY-RESPONSE AND STABILITY CHARACTERISTICS OF THE DOUGLAS D-558-II AIRPLANE AS DETERMINED FROM TRANSIENT RESPONSE TO A MACH NUMBER OF 0.96. Euclid C. Holleman. September 1952. 35p. diagrs., tabs. (NACA RM L52E02)

By an application of the Fourier transformation to transient-flight data the longitudinal frequency response of the Douglas D-558-II airplane has been determined over a Mach number range of 0.62 to 0.96 at altitudes between 21,000 and 43,000 feet; however,

the results have been reduced to airplane stability derivatives which are presented as functions of Mach number.

NACA RM L52E06a

FLUTTER OF A 60° DELTA WING (NACA 65A003 AIRFOIL) ENCOUNTERED AT SUPERSONIC SPEEDS DURING THE FLIGHT TEST OF A ROCKET-PROPELLED MODEL. Joseph H. Judd and William T. Lauten, Jr. September 1952. 24p. diagrs., photos., tabs. (NACA RM L52E06a)

Results of flight tests of a 60° delta-wing (NACA 65A003 airfoil section) airplane configuration indicated wing flutter during the latter part of accelerating flight to the peak Mach number of 2.29, and during decelerating flight to a Mach number of 1.07. An abrupt change in mode of flutter, from a ratio of flutter to torsional frequency of 0.625 to approximately 1.0 at a Mach number of 1.72, was observed. The flight-time history, natural frequencies of vibrations, and structural influence coefficients of the wing, and the mass, moment of inertia, and center of gravity of streamwise strips of the wing are presented.

NACA RM L52E12a

AN EXPERIMENTAL INVESTIGATION OF THE EFFECT OF HIGH-PRESSURE TAILPIPE LENGTH ON THE PERFORMANCE OF SOLID-PROPELLANT MOTORS FOR ROCKET-POWERED AIRCRAFT. Charles J. Rodriguez. August 1952. 37p. diagrs., tabs. (NACA RM L52E12a)

The effect of high-pressure exhaust duct length on the performance of solid-propellant rocket motors has been evaluated from thrust-stand tests. For increasing pipe lengths, boundary-layer development progressively reduces the effective throat area, with resultant marked increases in operating pressure and thrust. Duct losses result in lower values of impulse as pipe length is increased. The magnitude of these losses is within practical limits. The increases in operating pressure may prove significant when structural considerations are critical.

NACA RM L52E14

AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK WING-FUSELAGE COMBINATION AND THE FUSELAGE ALONE OBTAINED IN THE LANGLEY 8-FOOT TRANSONIC TUNNEL. Robert S. Osborne and John P. Mugler, Jr. September 1952. 71p. diagrs., photos., tabs. (NACA RM L52E14)

A fuselage and a wing-fuselage combination employing a wing with 45° sweepback of the 0.25-chord line, aspect ratio 4, taper ratio 0.6, and NACA 65A006 airfoil sections were tested at Mach numbers from 0.6 to 1.13 at angles of attack up to 36°. Force, moment, and base pressure characteristics were determined and tuft patterns were photographed. Maximum lift was reached at Mach numbers from 0.6 to 0.92.

NACA RM L52E15

WIND-TUNNEL INVESTIGATION OF A RAM-JET CANARD MISSILE MODEL HAVING A WING AND CANARD SURFACES OF DELTA PLAN FORM WITH 70° SWEPT LEADING EDGES. LONGITUDINAL AND LATERAL STABILITY AND CONTROL CHARACTERISTICS AT A MACH NUMBER OF 1.60. M. Leroy Spearman and Ross B. Robinson. August 1952. 63p. diagrs., photo., tabs. (NACA RM L52E15)

An investigation has been conducted in the Langley 4- by 4-foot supersonic pressure tunnel to determine the longitudinal and lateral stability and control characteristics of a ram-jet canard missile at a Mach number of 1.60 and a Reynolds number of 3.83×10^6 based on the wing mean aerodynamic chord. The model had a wing and vertical and horizontal canard surfaces of delta plan form with 70° swept leading edges. Nacelles were mounted in the vertical plane on unswept pylons near the rear of the model. The effects of vertical canard size and nacelle location on the stability characteristics were investigated. The tests covered an angle-of-attack range from -4° to 14° and an angle-of-sideslip range from -4° to 10°. The aileron deflection range was ±10° and the canard controls were deflected up to 12°.

NACA RM L52G07

WIND-TUNNEL INVESTIGATION OF THE LOW-SPEED STATIC AND ROTARY STABILITY DERIVATIVES OF A 0.13-SCALE MODEL OF THE DOUGLAS D-558-II AIRPLANE IN THE LANDING CONFIGURATION. M. J. Queijo and Evalyn G. Wells. August 1952. 17p. diagrs., photo., tab. (NACA RM L52G07)

An investigation was made in the Langley stability tunnel to determine the low-speed static and rotary stability derivatives of a 0.13-scale model of the Douglas D-558-II in the landing configuration. Results are presented for the model with tail surfaces on and off for an angle-of-attack range from 0° to about 24°.

NACA RM L52K14a

AN ANALYSIS OF THE LATERAL STABILITY OF THE DOUGLAS D-558-II AIRPLANE EQUIPPED WITH A YAW DAMPER, WITH SPECIAL REFERENCE TO THE EFFECT OF YAW-DAMPER RATE-GYRO SPIN-AXIS ORIENTATION. Ordway B. Gates, Jr., Albert A. Schy, and C. H. Woodling. March 1953. 36p. diagrs., tabs. (NACA RM L52K14a)

An investigation has been made to determine the effect of a yaw damper on the lateral stability of the Douglas D-558-II airplane. Effects of rate-gyro spin-axis inclination and possible advantages of orientation in the direction of the airplane Y-axis are considered. A combination of control gearing and rate-gyro inclination is recommended which should give satisfactory stability to the airplane for the flight conditions considered. Also, a particular auxiliary control surface is proposed for use with the damper and the characteristics of the surface are discussed. Airplane motions subsequent to an initial disturbance in sideslip are presented for each flight condition, with and without the yaw damper assumed installed.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L52K21a

EFFECTS OF CHORD-EXTENSION AND DROOP OF COMBINED LEADING-EDGE FLAP AND CHORD-EXTENSION ON LOW-SPEED STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A 35° SWEPTBACK WING WITH PLAIN FLAPS NEUTRAL OR DEFLECTED. Byron M. Jaquet. January 1953. 34p. diagrs., photos. (NACA RM L52K21a)

Low-speed results are presented of an investigation made in the Langley stability tunnel to determine mainly the effects of a chord-extension and droop of the combined leading-edge flap and chord-extension on static longitudinal characteristics of an airplane model having a 35° sweptback wing with plain flaps neutral or deflected. Comparisons are made between a drooped leading-edge flap and chord-extension combination and a previously investigated slat arrangement.

NACA RM L53E05

FLIGHT DETERMINATION OF THE PRESSURE RECOVERY AND DRAG CHARACTERISTICS OF A TWIN SIDE-INLET MODEL AT TRANSONIC SPEEDS. Howard S. Carter and Charles F. Merlet. July 1953. 35p. diagrs., photos., tabs. (NACA RM L53E05)

External-drag and total-pressure-recovery data are presented for a twin side-inlet configuration between Mach numbers 0.8 and 1.45, and between mass-flow ratios of 0.3 and 0.9. At mass-flow ratios of 0.8 and 0.9, the supersonic external-drag coefficient was about 0.35, and the subsonic drag coefficient was about 0.12. The maximum total-pressure recovery varied from 0.92 at a Mach number of 0.8 and a mass-flow ratio of 0.8 to 0.77 at a Mach number of 1.45 and a mass-flow ratio of 0.9. Oscillating flow, which occurred at reduced mass-flow ratios throughout the Mach number range, affected the total drag as much as ±0.10. The Reynolds number per foot varied from 4×10^6 to 10×10^6.

NACA RM L53H31

SOME LOW-SPEED WIND-TUNNEL EXPERIMENTS PERTAINING TO THE LONGITUDINAL STABILITY CHARACTERISTICS OF A 35° SWEPT-WING MODEL AND AN UNSWEPT-WING MODEL. Byron M. Jaquet. October 1953. 43p. diagrs., photos., tab. (NACA RM L53H31)

Results are presented of an investigation made in the Langley stability tunnel to determine the effects of various leading-edge flow-control notches, leading- and trailing-edge extensions, horizontal-tail span, wing sweep, aspect ratio of an unswept wing, and horizontal-tail position on the static longitudinal stability characteristics of an airplane model having swept tail surfaces.

NACA RM L53J01

CALCULATED LATERAL FREQUENCY RESPONSE AND LATERAL OSCILLATORY CHARACTERISTICS FOR SEVERAL HIGH-SPEED AIRPLANES IN VARIOUS FLIGHT CONDITIONS. Byron M. Jaquet. December 1953. 72p. diagrs., tabs. (NACA RM L53J01)

Results are presented to show for several high-speed airplanes the effects of Mach number and altitude on the period and damping of the lateral oscillation, the lateral frequency response, and the response to a sinusoidal lateral gust distribution. Aeroelastic and unsteady lift effects have not been included in the calculations. The results are presented without analysis.

NACA RM L54E04

EFFECT OF WING FLEXIBILITY ON THE DAMPING IN ROLL OF A NOTCHED DELTA WING-BODY COMBINATION BETWEEN MACH NUMBERS 0.6 AND APPROXIMATELY 2.2 AS DETERMINED WITH ROCKET-PROPELLED MODELS. William M. Bland, Jr. June 1954. 20p. diagrs., photos. (NACA RM L54E04)

An experimental investigation employing sting-mounted rocket-propelled models in free flight at approximately zero lift has been made to determine the effect of wing flexibility on the damping-in-roll characteristics of a wing-body combination in the range of Mach numbers from 0.6 to approximately 2.2. The wing used in this investigation had a notched delta plan form of aspect ratio 3.2 with leading edges swept back 55°, trailing edges swept back 10°, and NACA 65A003 airfoil sections parallel with the model center line. Wing flexibility was varied by changing from solid-steel construction to solid-magnesium construction.

NACA RM L54E05a

INVESTIGATION OF THE JET EFFECTS ON A FLAT SURFACE DOWNSTREAM OF THE EXIT OF A SIMULATED TURBOJET NACELLE AT A FREE-STREAM MACH NUMBER OF 2.02. Walter E. Bressette. June 1954. 38p. diagrs., photos., tab. (NACA RM L54E05a)

Static-pressure surveys were made on a flat surface that was located in the vicinity of the propulsive jet from a convergent sonic nozzle at a free-stream Mach number of 2.02. It was found that shock waves, formed in the external flow from the presence of the propulsive jet, impinged on the flat surface and greatly altered the pressure distribution. The integration of this pressure distribution resulted in a strong incremental lift on the flat surface.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L54E27

STUDY OF THE ATTACK OF AN AUTOMATICALLY CONTROLLED INTERCEPTOR ON A MANEUVERING BOMBER WITH EMPHASIS ON PROPER COORDINATION OF LIFT-ACCELERATION AND ROLL-ANGLE COMMANDS DURING ROLLING MANEUVERS. Charles W. Mathews. August 1954. 52p. diagrs., photo., tabs. (NACA RM L54E27)

The study is primarily concerned with the coordination or combination of lift-acceleration and roll-attitude commands of an automatic interceptor. The results were obtained from an investigation on an analog computer of encounters of an interceptor with a maneuvering bomber. The effects on tracking errors of several types of coordination are discussed and some information on the effect of interceptor rolling performance on tracking is also presented.

NACA RM L55C17

LOW-SPEED INVESTIGATION OF THE EFFECTS OF WING TANKS AND SPEED BRAKES ON THE STATIC STABILITY OF A MODEL HAVING A 40° SWEPT WING. William C. Sleeman, Jr., and William J. Alford, Jr. May 1955. 62p. diagrs., photo., tabs. (NACA RM L55C17)

A wind-tunnel investigation was conducted to determine the effects of wing tanks and speed brakes on the directional stability characteristics of a complete model having sweptback wing and tail surfaces. The wing had 40° sweepback of the quarter-chord line, aspect ratio 3.45, taper ratio 0.578, and had NACA 64A010 airfoil sections normal to the quarter-chord line. The two wing tanks were of fineness ratio 10.4 and were pylon-mounted at approximately the 22-percent-wing-semispan station. The test results include effects of several modifications investigated to improve the directional stability of the model, such as dorsal fins and an extended vertical tail.

NACA RM L55E03

STATISTICAL MEASUREMENTS OF LANDING-CONTACT CONDITIONS OF A HEAVY BOMBER. Norman S. Silsby and Eziaslav N. Harrin. June 1955. 22p. diagrs., tabs. (NACA RM L55E03)

Statistical measurements of landing-contact conditions have been obtained by a special photographic technique for 144 landings of a heavy bomber airplane during routine daytime operations at Carswell Air Force Base, Fort Worth, Texas. From these measurements, sinking speeds, bank angles, rolling velocities, and horizontal speeds at the instant before contact have been evaluated and a limited statistical analysis of the results has been made.

NACA RM L55E06

AN INVESTIGATION OF JET EFFECTS ON ADJACENT SURFACES. Walter E. Bressette and Maxime A. Faget. June 1955. 13p. diagrs. (NACA RM L55E06)

Static-pressure surveys were made on a flat surface that was located in the vicinity of a propulsive jet issuing into subsonic and supersonic free-stream flow. In conjunction with the static-pressure surveys a temperature analysis was made at subsonic speeds. There was also a preliminary investigation of the acoustic pressure fluctuations from the propulsive jet made at supersonic speeds. The steady pressure loads as well as the temperature change on adjacent surfaces due to the presence of a propulsive jet at free-stream subsonic speeds are shown to be insignificant, whereas at free-stream supersonic speeds the steady pressure loads were found to increase greatly on surfaces downstream of the propulsive jet exit.

NACA RM L55E09b

REDUCTION OF HYDRODYNAMIC IMPACT LOADS FOR WATERBORNE AIRCRAFT. Emanuel Schnitzer. July 1955. 17p. diagrs. (NACA RM L55E09b)

Recent NACA research aimed at the reduction of water loads on both hull and hydro-ski-equipped seaplanes is presented. It is shown that hull loads can be reduced by proper trim programming from elevator action and by use of high dead rise. For the hydro-ski-equipped seaplanes, loads are shown to be reduced by a decrease of ski beam or length and by mounting the ski on either conventional shock struts or on a new type of frequency-discriminating shock strut.

NACA RM L55E10

EXPERIMENTAL DRAG COEFFICIENTS OF ROUND NOSES WITH CONICAL WINDSHIELDS AT MACH NUMBER 2.72. Jim J. Jones. June 1955. 18p. diagrs., photos. (NACA RM L55E10)

An exploratory investigation at Mach number 2.72 has been made to show the decrease in the drag of a round-nose model achieved by mounting a small cone on a rod ahead of the nose. The geometric parameters which were varied were the cone-base diameter, cone angle, and rod length. On one model the rod was replaced by two off-axis legs. All models showed large decreases in drag compared to that of the round nose alone.

NACA RM L55E12

SIMPLIFIED PROCEDURES FOR ESTIMATING FLAP-CONTROL LOADS AT SUPERSONIC SPEEDS. K. R. Czarnecki and Douglas R. Lord. May 1955. 14p. diagrs. (NACA RM L55E12)

An investigation has been made to determine the possibility of using simplified procedures for the estimation of control loads at supersonic speeds. The results of the investigation indicate that relatively simple procedures are possible for the estimation of loadings on flap-type controls at supersonic speeds for the case where no flow separation occurs ahead of the hinge line. For tip-type controls, the simplified procedures have been tested only in a few cases and need further development. For controls with swept hinge lines, experimental data are lacking, but

DECLASSIFIED NACA RESEARCH REPORTS

it is anticipated that the procedures developed for the unswept hinge-line controls will apply provided that there is no flow separation at the hinge line or that the sweep angle is not too large. In general, the loadings predicted by the simplified procedures are in better agreement with experiment than is unmodified three-dimensional linear theory.

NACA RM L55E13

AN INVESTIGATION OF LOADS ON AILERONS AT TRANSONIC SPEEDS. Jack F. Runckel and W. H. Gray. May 1955. 8p. diagrs. (NACA RM L55E13)

Some load characteristics of unbalanced ailerons for three thin wings varying in sweep are presented for Mach numbers from 0.80 to 1.05.

NACA RM L55E18c

LANDING CONDITIONS FOR LARGE AIRPLANES IN ROUTINE OPERATIONS. Norman S. Silsby and Eziaslav N. Harrin. July 1955. 10p. diagrs. (NACA RM L55E18c)

Measurements have been obtained by means of a specially developed photographic method of landing contact conditions of some commercial transports, the Boeing KC-97 tanker, the Boeing B-47 jet bomber, and the Convair B-36 bomber. From these measurements, vertical velocities and airspeeds at contact have been evaluated and a brief statistical analysis of the results, including the effect of horizontal gusts on the landing conditions for the transports, has been made.

NACA RM L55E20b

SOME FACTORS AFFECTING THE VARIATION OF PITCHING MOMENT WITH SIDESLIP OF AIRCRAFT CONFIGURATIONS. Edward C. Polhamus. July 1955. 29p. diagrs. (NACA RM L55E20b)

A brief study of available wind-tunnel data with regard to the variation of pitching-moment coefficient with sideslip angle is presented. The effects of such factors as wing plan form, wing-body interference, and tail location are illustrated and discussed, and regions where additional data are needed are indicated.

NACA RM L55E25

EFFECTS OF COMBINING AUXILIARY BLEED WITH EJECTOR PUMPING ON THE POWER REQUIREMENTS AND TEST-SECTION FLOW OF AN 8-INCH BY 8-INCH SLOTTED TUNNEL. B. H. Little, Jr., and James M. Cubbage, Jr. July 1955. 44p. diagrs., photo. (NACA RM L55E25)

The effects of using varying amounts of auxiliary bleed for slot-flow removal in an 8-inch by 8-inch slotted tunnel were determined for two ejector configurations. Auxiliary bleed adversely affected the test-section Mach number distributions for the ejector with slot-flow reentry flaps 1 tunnel height in length, but this effect was relieved when the flaps were shortened. Total-horsepower requirements were always reduced by using some auxiliary bleed. The amounts of bleed required for minimum total horsepower were determined by the ejector characteristics and the test-section Mach number.

NACA RM L55E25a

EXPERIMENTAL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE EFFECTS OF LEADING-EDGE RADIUS ON THE AERODYNAMIC CHARACTERISTICS OF A SWEPTBACK-WING—FUSELAGE COMBINATION WITH LEADING-EDGE FLAPS AND CHORD-EXTENSIONS. Kenneth P. Spreemann. July 1955. 42p. diagrs., photo., tabs. (NACA RM L55E25a)

A limited investigation was made at high subsonic speeds to determine the effects of wing leading-edge radius on the aerodynamic characteristics of a sweptback-wing—fuselage combination with leading-edge flaps and chord-extensions. The basic wing had 45° sweepback, aspect ratio 4, taper ratio 0.3, and NACA 65A006 airfoil section. The investigation was made in the Langley high-speed 7- by 10-foot tunnel over a Mach number range of 0.80 to 0.92 and an angle-of-attack range of -2° to 24°. The results indicate that the changes in leading-edge radius employed in this investigation generally had only small effects on the aerodynamic characteristics of the model and the altered leading edges usually were less favorable than the normal NACA 65A006 airfoil section.

NACA RM L57A30a

THEORETICAL INVESTIGATION OF THE EFFECT OF RUDDER AND STABILIZER DEFLECTIONS ON THE ANGLES OF ATTACK AND SIDESLIP IN RAPID ROLLS. C. H. Woodling. March 1957. 43p. diagrs., tabs. (NACA RM L57A30a)

A theoretical investigation has been made of the effect of rudder and stabilizer deflections on the angles of attack and sideslip in rapid rolls. Expressions are derived from the five-degree-of-freedom airplane equations of motion which define the rudder and stabilizer motions necessary to maintain constant angle of attack and zero sideslip during an aileron roll. The control motions calculated by using these expressions are useful in determining the magnitude and direction of the rudder and stabilizer deflections that might be applied by a pilot or by automatic controls to maintain small variations in the angles of attack and sideslip during aileron rolls.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1277

INTERACTION OF A FREE FLAME FRONT WITH A TURBULENCE FIELD. Maurice Tucker. 1956. ii, 19p. diagrs., tabs. (NACA Rept. 1277. Supersedes TN 3407)

Theoretical values are obtained for the root-mean-square flame-generated turbulence velocities and the attenuating pressure fluctuations resulting from a linearized interaction of a constant-pressure combustion front with a field of isotropic turbulence. The anisotropic flame-generated turbulence is found to be of about the same intensity as the incident turbulence. A brief discussion of turbulent flame speed is given. Directly at the flame front the noise pressure levels characterizing the pressure fluctuations are fairly intense (59 to 81 decibels) even at moderate approach-flow turbulence intensities.

NACA Rept. 1278

EFFECT OF INTERACTION ON LANDING-GEAR BEHAVIOR AND DYNAMIC LOADS IN A FLEXIBLE AIRPLANE STRUCTURE. Francis E. Cook and Benjamin Milwitzky. 1956. ii, 30p. diagrs., tabs. (NACA Rept. 1278. Supersedes TN 3467)

The effects of interaction between a landing gear and a flexible airplane structure on the behavior of the landing gear and the loads in the structure have been studied by treating the equations of motion of the airplane and the landing gear as a coupled system where the landing gear is considered to have nonlinear characteristics. Numerical examples, based on the characteristics of two large airplanes, show the effects of interaction on the loads in the landing gear and in the structure. The effects of neglecting interaction and using the landing-gear forcing function for a rigid body in a dynamic analysis of a flexible airframe are also discussed.

NACA Rept. 1279

THEORETICAL ANALYSIS OF INCOMPRESSIBLE FLOW THROUGH A RADIAL-INLET CENTRIFUGAL IMPELLER AT VARIOUS WEIGHT FLOWS. James J. Kramer, Vasily D. Prian, and Chung-Hua Wu. 1956. ii, 16p. diagrs., tab. (NACA Rept. 1279. Supersedes TN 3448; TN 3449)

A method for the solution of the incompressible nonviscous flow through a centrifugal impeller, including the inlet region, is presented. Several numerical solutions are obtained for four weight flows through an impeller at one operating speed. These solutions are refined in the leading-edge region. The results are presented in a series of figures showing streamlines and relative velocity contours. A comparison is made with the results obtained by using a rapid approximate method of analysis.

NACA Rept. 1280

THEORETICAL INVESTIGATION OF FLUTTER OF TWO-DIMENSIONAL FLAT PANELS WITH ONE SURFACE EXPOSED TO SUPERSONIC POTENTIAL FLOW. Herbert C. Nelson and Herbert J. Cunningham. 1956. ii, 24p. diagrs., tabs. (NACA Rept. 1280. Supersedes TN 3465)

A Rayleigh type analysis is used to treat the flutter of a two-dimensional flat panel supported at its leading and trailing edges and subjected to a middle-plane tensile force, with a supersonic stream over its upper surface and still air below. Numerical results in the form of stability boundaries are presented for determining some effects of number of modes, Mach number, densities of the supersonic stream and still air, panel mass and stiffness, edge fixity, structural damping, and middle-plane tensile force. Comparison is made with a few experimental results.

NACA Rept. 1286

PROPAGATION OF A FREE FLAME IN A TURBULENT GAS STREAM. William R. Mickelsen and Norman E. Ernstein. 1956. ii, 26p. diagrs., photos., tabs. (NACA Rept. 1286. Supersedes TN 3456)

Effective turbulent free-flame speeds measured in turbulent, flowing propane-air mixtures were found to have statistical distributions about mean values. The statistical spread was greater for rich and lean fuel-air ratios and at high turbulence intensities. The measured flame speeds, together with hot-wire-anemometer measurements, formed a basis for comparison with three theories and other types of flames. Although the free-flame speeds are lower than those for turbulent Bunsen and stabilized flames, values calculated from the Tucker analysis and a modified Scurlock-Grover analysis seem to form an upper limit to the turbulent free-flame-speed data.

NACA Rept. 1290

DEVELOPMENT OF CRAZE AND IMPACT RESISTANCE IN GLAZING PLASTICS BY MULTIAXIAL STRETCHING. G. M. Kline, I. Wolock, B. M. Axilrod, M. A. Sherman, D. A. George, and V. Cohen, National Bureau of Standards. 1956. ii, 16p. diagrs., photos., tabs. (NACA Rept. 1290)

The loss of strength of cast polymethyl methacrylate plastic as a result of crazing is of considerable importance to the aircraft industry. In the course of this study of crazing the following factors were examined: (1) The effect of stress-solvent crazing on tensile strength of polymethyl methacrylate; (2) the critical stress and strain for onset of crazing at various temperatures; (3) the effect of molecular weight on crazing; and (4) the effect of multiaxial stretching on crazing of polymethyl methacrylate and other acrylic glazing materials.

NACA Rept. 1291

LIFT HYSTERESIS AT STALL AS AN UNSTEADY BOUNDARY-LAYER PHENOMENON. Franklin K. Moore. 1956. ii, 10p. diagrs., tab. (NACA Rept. 1291. Supersedes TN 3571)

With the problem of rotating compressor stall in view, an unsteady boundary-layer calculation is made to find the unsteady increment of lift of a stalled elliptic airfoil in a flow of time-dependent incidence. The analysis indicates a counterclockwise hysteresis loop of the lift curve, the various forms of which are discussed.

NACA Rept. 1293

SIMILAR SOLUTIONS FOR THE COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH HEAT TRANSFER AND PRESSURE GRADIENT. Clarence B. Cohen and Eli Reshotko. 1956. ii, 38p. diagrs., tabs. (NACA Rept. 1293. Supersedes TN 3325)

Stewartson's equations for the compressible laminar boundary layer with pressure gradient and heat transfer are solved for pressure gradients varying from that causing separation to the infinitely favorable gradient and for wall temperatures from absolute zero to twice the free-stream stagnation temperature. For the case of favorable pressure gradients with heated walls, it is shown that the velocity within a portion of the boundary layer must exceed the local external velocity. The variation of a Reynolds analogy parameter, which indicates the ratio of skin friction to heat transfer, is from zero to 7.4 for a surface of temperature twice the free-stream stagnation temperature and from zero to 2.8 for a surface held at absolute zero, where the value 2 applies to a flat plate.

NACA Rept. 1294

THE COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH HEAT TRANSFER AND ARBITRARY PRESSURE GRADIENT. Clarence B. Cohen and Eli Reshotko. 1956. ii, 16p. diagrs., tabs. (NACA Rept. 1294. Supersedes TN 3326)

An approximate method for the calculation of the compressible laminar boundary layer with heat transfer and arbitrary pressure gradient, based on Thwaites' correlation concept, is presented. With the definition of dimensionless shear and heat-transfer parameters and an assumed correlation of these parameters in terms of a momentum parameter, a complete system of relations for calculating skin friction and heat transfer results. Knowledge of velocity or temperature profiles is not necessary in using this calculation method. When the method is applied to a convergent-divergent, axially symmetric rocket nozzle, it shows that high rates of heat transfer are obtained at the initial stagnation point and at the throat of the nozzle. Also indicated are negative displacement thicknesses in the convergent portion of the nozzle; these occur because of the high density within the lower portions of the cooled boundary layer.

NACA Rept. 1295

AN ANALYSIS OF ONCE-PER-REVOLUTION OSCILLATING AERODYNAMIC THRUST LOADS ON SINGLE-ROTATION PROPELLERS ON TRACTOR AIRPLANES AT ZERO YAW. Vernon L. Rogallo, Paul F. Yaggy, and John L. McCloud, III. 1956. ii, 30p. diagrs., photos. (NACA Rept. 1295. Supersedes TN 3395)

A simplified procedure is shown for calculating the once-per-revolution oscillating aerodynamic thrust loads on propellers of tractor airplanes at zero yaw. The only flow field information required is a knowledge of the upflow angles at the horizontal center line of the propeller disk. Methods are presented whereby these angles may be determined by theoretical procedures.

NACA RM L57D19b

RECENT DATA ON TIRE FRICTION DURING LANDING. Sidney A. Batterson. June 1957. 7p. diagrs. (NACA RM L57D19b)

An investigation was made at the Langley landing loads track to obtain data on the coefficient of friction during wheel spin-up. A landing gear was tested at horizontal velocities ranging from 0 to 180 feet per second together with vertical velocities of 7.0 and 9.3 feet per second. The results indicate the effect of forward speed and tire inflation pressure on the coefficient of friction.

CURRENT NACA RESEARCH REPORTS

NACA TM 1428

EFFECT OF FATIGUE CRACK ON STATIC STRENGTH: 2014-T6, 2024-T4, 6061-T6, 7075-T6 OPEN-HOLE MONOBLOC SPECIMENS. Glenn E. Nordmark and Ian D. Eaton, Aluminum Company of America. May 1957. 22p. diagrs., tabs. (NACA TM 1428)

Static tensile test results are presented for specimens of 2014-T6, 2024-T4, 6061-T6, and 7075-T6 aluminum alloy containing fatigue cracks. The results are found to be in good agreement with the results reported for similar tests from other sources. The results indicate that the presence of a fatigue crack reduced the static strength, in all cases, by an amount larger than the corresponding reduction in net area; the 6061-T6 alloy specimens were least susceptible to the crack and the 7075-T6 alloy specimens most susceptible. It is indicated that a 7075-T6 specimen may develop as little as one-third of the expected static tensile strength when the fatigue crack has consumed only one-fourth of the original area.

NACA TN 3858

A LOW-SPEED EXPERIMENTAL INVESTIGATION OF THE EFFECT OF A SANDPAPER TYPE OF ROUGHNESS ON BOUNDARY-LAYER TRANSITION. Albert E. von Doenhoff and Elmer A. Horton. October 1956. 45p. diagrs., photos. (NACA TN 3858) CORRECTED COPY

An investigation conducted in the Langley low-turbulence pressure tunnel at low speeds showed that for sandpaper-type roughness the occurrence of transition could be correlated on the basis of a local roughness Reynolds number based on the size of the roughness and the velocity at the top of the roughness. The extent of the roughened area does not appear to have an important effect on the critical value of the roughness Reynolds number.

NACA TN 3943

A POWER-SERIES SOLUTION FOR THE UNSTEADY LAMINAR BOUNDARY-LAYER FLOW IN AN EXPANSION WAVE OF FINITE WIDTH MOVING THROUGH A GAS INITIALLY AT REST. Nathaniel B. Cohen. June 1957. 56p. diagrs., tabs. (NACA TN 3943)

The equations of motion and energy for the laminar boundary-layer flow in an expansion fan moving into undisturbed fluid were considered. Infinite power-series solutions were indicated and the first three terms of each series were numerically evaluated. Validity of the numerical results was restricted to the region near the leading edge of the fan. Results were compared with those given by a solution which considered the expansion fan as an isentropic wave of zero thickness. The solutions were shown to be very different, qualitatively as well as quantitatively. Singularities in the flow field were discussed in regard to both finite- and zero-width expansion-wave solutions.

NACA TN 3944

AN INTEGRAL SOLUTION TO THE FLAT-PLATE LAMINAR BOUNDARY-LAYER FLOW EXISTING INSIDE AND AFTER EXPANSION WAVES AND AFTER SHOCK WAVES MOVING INTO QUIESCENT FLUID WITH PARTICULAR APPLICATION TO THE COMPLETE SHOCK-TUBE FLOW. Robert L. Trimpi and Nathaniel B. Cohen. June 1957. ii, 180 p. diagrs., tab. (NACA TN 3944)

A solution to the unsteady two-dimensional laminar boundary-layer flow inside centered expansion waves and behind both centered expansion waves and shock waves is obtained by utilizing an extension of the Kármán-Pohlhausen method. The reduced hyperbolic differential equations are integrated in closed form for flow behind shock waves and by numerical methods for the flow inside or following expansion waves. An integral technique is applied at the discontinuities existing at the trailing edge of the expansion fan and at contact discontinuities (entropy discontinuities) so that the characteristic solution may proceed across these discontinuities. The solution to the two-dimensional unsteady laminar boundary layer existing at all points in an air-air shock tube is obtained by this method. A much shorter approximate method of solution is devised and is found to agree favorably with this method. This approximate method is used to predict the flow in hydrogen-air and helium-air shock tubes. Plots of wall heat-transfer rate and skin friction in air-air, helium-air, and hydrogen-air shock tubes are presented.

NACA TN 3952

EFFECTS OF HORIZONTAL-TAIL POSITION AND A WING LEADING-EDGE MODIFICATION CONSISTING OF A FULL-SPAN FLAP AND A PARTIAL-SPAN CHORD-EXTENSION ON THE AERODYNAMIC CHARACTERISTICS IN PITCH AT HIGH SUBSONIC SPEEDS OF A MODEL WITH A 45° SWEPTBACK WING. William D. Morrison, Jr., and William J. Alford, Jr. June 1957. 37p. diagrs., photo., tab. (NACA TN 3952. Supersedes RM L53E06)

The effects of horizontal-tail position (13.9 percent wing semispan below and 13.9 and 25.6 percent semispan above chord plane extended) on the pitch characteristics of a general research model having full-span wing leading-edge deflection and a partial-span chord-extension have been determined at Mach numbers of 0.40 to 0.93 at Reynolds numbers ranging from about 2,000,000 to 3,000,000. Lift, drag, and pitching moments were determined for three horizontal-tail angles at all Mach numbers investigated for angles of attack ranging from -2° to 24° except at the higher Mach numbers where tunnel choking restricted this angle range.

NACA TN 3954

A THEORY FOR THE LATERAL RESPONSE OF AIRPLANES TO RANDOM ATMOSPHERIC TURBULENCE. John M. Eggleston. May 1957. i, 75p. diagrs., tabs. (NACA TN 3954)

The power spectra of the lateral motions of an airplane flying through continuous random isotropic turbulence are derived in terms of airplane transfer functions, the power spectra of coefficients relating the lateral moments and forces to gust velocities, and the power spectra of the three orthogonal components of gust velocities along the flight path. Random variations of gust velocities across the span and along the fuselage are considered. Three example airplanes are used to demonstrate the method, trends, and simplifications. Comparisons with less comprehensive methods are drawn.

NACA TN 3957

SOME EFFECTS OF TAIL HEIGHT AND WING PLAN FORM ON THE STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF A SMALL-SCALE MODEL AT HIGH SUBSONIC SPEEDS. Albert G. Few, Jr., and Thomas J. King, Jr. May 1957. 62p. diagrs., photo. (NACA TN 3957. Supersedes RM L54G12)

The present paper presents some effects of horizontal-tail height and wing plan form on the static longitudinal characteristics of a complete model at high subsonic speeds. All wings had an aspect ratio of 3, quarter-chord sweep angles of 25°, 30°, and 35°, and NACA 65A004 airfoil sections parallel to the free stream. The Mach number range extended from about 0.80 to 0.94 with corresponding Reynolds numbers ranging from about 1.17×10^6 to 1.29×10^6. The drag due to lift increases with increasing sweep through the Mach number range. In relation to the pitch-up problem, the low-tail arrangement provides, in general, stable breaks and fairly linear pitching-moment curves above an angle of attack of approximately 4° for all wing plan forms at the low Mach numbers but not at the highest test Mach number.

NACA TN 3970

THIN AIRFOIL THEORY BASED ON APPROXIMATE SOLUTION OF THE TRANSONIC FLOW EQUATION. John R. Spreiter and Alberta Y. Alksne. May 1957. 82p. (NACA TN 3970)

A method is presented for the approximate solution of the nonlinear equations of transonic flow theory. Solutions are found for two-dimensional flows at a Mach number of 1 and for purely subsonic and purely supersonic flows. Results are obtained in closed analytic form for a large and significant class of nonlifting airfoils. At a Mach number of 1 general expressions are given for the pressure distribution on an airfoil of specified geometry and for the shape of an airfoil having a prescribed pressure distribution. Extensive comparisons are made with available data, particularly for a Mach number of 1, and with existing solutions.

NACA TN 3971

ON FLOW OF ELECTRICALLY CONDUCTING FLUIDS OVER A FLAT PLATE IN THE PRESENCE OF A TRANSVERSE MAGNETIC FIELD. Vernon J. Rossow. May 1957. 54p. tabs. (NACA TN 3971)

Several basic boundary-layer solutions for the velocity and temperature profiles are found for flow of electrically conducting fluid over a flat plate in the presence of a transverse magnetic field. It is concluded that the skin friction and the heat-transfer rate are reduced when the transverse magnetic field is fixed relative to the plate and increased when fixed relative to the fluid. The total drag is increased in all the cases studied.

NACA TN 3983

EFFECT OF STANDING TRANSVERSE ACOUSTIC OSCILLATIONS ON FUEL-OXIDANT MIXING IN CYLINDRICAL COMBUSTION CHAMBERS. William R. Mickelsen. May 1957. (i), 49p. diagrs. (NACA TN 3983)

Vapor fuel-oxidant mixing is analyzed for standing transverse acoustic fields simulating those existing in screeching or screaming combustors. The additional mixing due to the acoustic field is shown to be a function of sound pressure and frequency, stream velocity, and turbulence. The effects of these parameters are shown graphically for a realistic range of combustor conditions. The fuel-oxidant ratio at various combustor stations is shown to have a cyclic fluctuation which is in phase with the pressure fluctuations. Possible mechanisms contributing to screech and scream are discussed.

NACA TN 3984

STATISTICAL STUDY OF AIRCRAFT ICING PROBABILITIES AT THE 700- AND 500-MILLIBAR LEVELS OVER OCEAN AREAS IN THE NORTHERN HEMISPHERE. Porter J. Perkins, William Lewis, and Donald R. Mulholland. May 1957. 31p. diagrs., tabs. (NACA TN 3984)

A statistical study is made of icing observations reported from weather reconnaissance aircraft flown by Air Weather Service (USAF). Wide areas of the Pacific, Atlantic, and Arctic Oceans were surveyed at fixed flight levels of 500 mb (18,000 ft) and 700 mb (10,000 ft). Icing statistics presented include the relative frequencies of the occurrence of icing, the estimated probability of flight in icing, and the relation of these probabilities to the frequencies of flight in clouds and cloud temperatures. Icing probabilities varied widely throughout the year from near zero in cold Arctic areas in winter up to 7 percent in areas where greater cloudiness and warmer temperatures prevail.

CURRENT NACA RESEARCH REPORTS

NACA TN 3986

COMPRESSIBLE LAMINAR BOUNDARY LAYER OVER A YAWED INFINITE CYLINDER WITH HEAT TRANSFER AND ARBITRARY PRANDTL NUMBER. Eli Reshotko and Ivan E. Beckwith. June 1957. (i), 86p. diagrs., tabs. (NACA TN 3986)

Numerical solutions to the equations for the compressible laminar boundary layer have been obtained for the flow in the stagnation region of an infinite cylinder in yaw for large free-stream Mach numbers and large yaw angles. The wall temperature was varied from zero to twice the stream stagnation temperature. Solutions are given for Prandtl numbers of 1 and 0.7. The results indicate that the heat-transfer coefficient decreases with yaw angle about as the square root of the cosine of the yaw angle for subsonic Mach numbers and somewhat less than the cosine of the yaw angle for Mach numbers greater than 2.

NACA TN 3992

CHARTS FOR ESTIMATING THE EFFECTS OF SHORT-PERIOD STABILITY CHARACTERISTICS ON AIRPLANE VERTICAL-ACCELERATION AND PITCH-ANGLE RESPONSE IN CONTINUOUS ATMOSPHERIC TURBULENCE. Kermit G. Pratt and Floyd V. Bennett. June 1957. 61p. diagrs., tabs. (NACA TN 3992)

Charts are presented from which the root-mean-square vertical acceleration and pitch angle in dimensionless form can be estimated for values of four other dimensionless parameters that describe the airplane short-period stability characteristics and the scale of atmospheric turbulence. The trends of the root-mean-square responses with each of the four parameters are discussed in terms of two significant combinations of the parameters involved. The vertical-acceleration response is compared with that of an airplane free to be disturbed in the vertical direction only. Some examples of chart application are given.

NACA TN 3996

INVESTIGATION OF A SHORT-ANNULAR-DIFFUSER CONFIGURATION UTILIZING SUCTION AS A MEANS OF BOUNDARY-LAYER CONTROL. Stafford W. Wilbur and James T. Higginbotham. June 1957. 33p. diagrs., photo. (NACA TN 3996)

A straight outer-wall annular diffuser having a center-body length of one-half the outer-body diameter and an area ratio of 1.9:1 has been investigated for mean inlet flow angles of 0° and 19.5° with an inlet Mach number of 0.26 in order to determine the effect of area suction applied on the inner wall. The entrance shape, number, and location of the openings through which the air was removed were varied. The auxiliary air flow was varied from 0 to approximately 4 percent of the main-stream air flow. For most of the configurations, significant improvement in performance was obtained over no control when a suction flow rate of as little as 1 percent was utilized. The diffuser-exit velocity distributions were also improved by the increase in suction area and by an increase in the amount of suction.

NACA TN 3999

EXPERIMENTAL INFLUENCE COEFFICIENTS AND VIBRATION MODES OF A BUILT-UP 45° DELTA-WING SPECIMEN. Eldon E. Kordes, Edwin T. Kruszewski, and Deene J. Weidman. May 1957. 41p. diagrs., photos., tabs. (NACA TN 3999)

Experimental influence coefficients and vibration modes and frequencies of a built-up 45° delta-wing specimen are presented. The symmetrical and antisymmetrical static influence coefficients were obtained on a three-point support. The first 10 vibration modes and frequencies were obtained for an essentially free-free condition. A detailed description of the structural properties of the specimen is also given.

NACA TN 4001

SOME CONSIDERATIONS OF HYSTERESIS EFFECTS ON TIRE MOTION AND WHEEL SHIMMY. Robert F. Smiley. June 1957. 45p. diagrs. (NACA TN 4001)

A theoretical study is made of the influence of tire hysteresis effects on the rolling motion and wheel shimmy of landing gears. The results of this study indicate that hysteresis forces and moments have a noticeable secondary influence on the landing-gear rolling behavior. Comparisons of the available experimental data with the corresponding theoretical predictions provide a fair confirmation of the theory.

NACA TN 4003

A VARIATIONAL THEOREM FOR CREEP WITH APPLICATIONS TO PLATES AND COLUMNS. J. Lyell Sanders, Jr., Harvey G. McComb, Jr., and Floyd R. Schlechte. May 1957. 23p. diagrs. (NACA TN 4003)

A variational theorem is presented for a body undergoing creep. Solutions to problems of creep bending and creep collapse of plates, columns, beams, and shells can be obtained by means of the direct methods of the calculus of variations in conjunction with the stated theorem. The application of the theorem is illustrated for plates and columns by the solution of two sample problems.

NACA TN 4004

SOME EFFECTS OF VALVE FRICTION AND STICK FRICTION ON CONTROL QUALITY IN A HELICOPTER WITH HYDRAULIC-POWER CONTROL SYSTEMS. B. Porter Brown and John P. Reeder. May 1957. 8p. diagr. (NACA TN 4004)

Flight tests have been made in a helicopter with hydraulic-power control systems to investigate the effect of various ratios of servovalve friction and stick friction, both with and without feel devices.

CURRENT NACA RESEARCH REPORTS

The tests showed that, when an objectionable amount of valve friction is present, some benefits can be gained by introducing stick friction. The addition of feel devices resulted in an overall improvement in the control systems and was therefore considered to be very desirable.

NACA TN 4006

INVESTIGATION AT TRANSONIC SPEEDS OF DEFLECTORS AND SPOILERS AS GUST ALLEVIATORS ON A 35° SWEPT WING. TRANSONIC-BUMP METHOD. Delwin R. Croom and Jarrett K. Huffman. June 1957. 19p. diagrs. (NACA TN 4006)

An investigation was made in the Langley high-speed 7- by 10-foot tunnel by means of the transonic-bump method to determine the gust-alleviation capabilities of a deflector control and a spoiler-deflector control when mounted on a 35° swept semispan wing having NACA 65A006 airfoil sections. The lift-curve slope was reduced by about 20 percent, the drag was increased, and a destabilizing effect was noted because of the addition of the controls.

NACA TN 4008

A SUMMARY OF GROUND-LOADS STATISTICS. John R. Westfall, Benjamin Milwitzky, Norman S. Silsby, and Robert C. Dreher. May 1957. 15p. diagrs. (NACA TN 4008)

This paper briefly summarizes the more important statistical data obtained by the NACA on the subject of ground loads. The information presented relates primarily to landing-impact and taxiing loads; however, some limited data are also presented on one phase of ground-handling loads, namely, braking friction. A number of experimental and theoretical papers dealing with various aspects of the subject are listed in the bibliography.

NACA TN 4009

SOME RESEARCH RESULTS ON SANDWICH STRUCTURES. Melvin S. Anderson and Richard G. Updegraff. June 1957. 12p. diagrs., photos. (NACA TN 4009)

The results of compressive-buckling tests of steel sandwich plates are given, and the significant parameters which affect the strength of the plates are discussed. The various types of sandwich construction are shown to be comparable on a weight-strength basis with conventional high-strength aluminum-alloy construction.

NACA TN 4011

SOME ASPECTS OF FAIL-SAFE DESIGN OF PRESSURIZED FUSELAGES. Paul Kuhn and Roger W. Peters. June 1957. 13p. diagrs. (NACA TN 4011)

Separate investigations have dealt with the critical crack length of flat sheets or of unstiffened cylinders and with the type of rupture experienced by stiffened cylinders. These investigations are correlated, supplemented by new tests, and combined into a uniform scheme for predicting critical crack length and type of rupture in stiffened pressurized cylinders.

NACA TN 4012

FATIGUE-CRACK PROPAGATION AND RESIDUAL STATIC STRENGTH OF BUILT-UP STRUCTURES. Herbert F. Hardrath and Richard E. Whaley. May 1957. 11p. diagrs. (NACA TN 4012)

Crack-propagation and static-strength tests in several types of built-up specimens and full-scale wings are reviewed. The results, to date, indicate that the rate of crack propagation is influenced strongly by the mode of connecting the skin to stringers and by the proportions of areas of the skin and stringers. The analysis of residual static strength of complex structures indicates the feasibility of applying simple methods, but the results are subject to questions regarding the redistribution of loads, interactions between various members, and such seemingly trivial considerations as whether or not a crack terminates at a rivet.

NACA TN 4015

THEORETICAL AND EXPERIMENTAL INVESTIGATIONS OF DELTA-WING VIBRATIONS. Edwin T. Kruszewski, Eldon E. Kordes, and Deene J. Weidman. June 1957. 11p. diagrs., photo., tab. (NACA TN 4015)

The results of some theoretical and experimental investigations of delta-wing vibrations are discussed. Nodal-line patterns and frequencies of a 45° built-up thin-skin delta-wing specimen obtained experimentally are compared with those calculated by the Levy method (with and without transverse shear) and by the Stein-Sanders method. Experimental nodal-line patterns and frequencies for a 60° thick-skin delta wing are also shown.

NACA TN 4021

NONUNIFORMITIES IN SHOCK-TUBE FLOW DUE TO UNSTEADY-BOUNDARY-LAYER ACTION. Harold Mirels and W. H. Braun. May 1957. 45p. diagrs. (NACA TN 4021)

The boundary layer along the walls of a shock tube induces pressure and velocity gradients within the core of potential flow. These nonuniformities are

CURRENT NACA RESEARCH REPORTS

evaluated herein for shock tubes in which the boundary layer is thin relative to the tube diameter and is either wholly laminar or wholly turbulent. The hot gas region between the shock wave and the contact surface is considered. Both the axial distributions at any instant and the temporal distributions at any axial position within this region are found. Numerical computations are presented for an air-air shock tube.

NACA TN 4022

ESTIMATION OF COMPRESSIBLE BOUNDARY-LAYER GROWTH OVER INSULATED SURFACES WITH PRESSURE GRADIENT. Gerald W. Englert. June 1957. 35p. diagrs. (NACA TN 4022)

The incompressible boundary-layer theory of Truckenbrodt was extended using a modified Stewartson-type transformation to include compressible boundary-layer development over insulated surfaces. The variation of turbulent shear stress with Mach number of the bounding potential stream was considered using the reference-temperature method of Eckert. The explicit technique of Truckenbrodt for determining profile parameter in the incompressible theory was unchanged so that profile parameter as well as momentum thickness can still be evaluated by simple quadratures in the present method. Good agreement of theory with experimental boundary-layer measurements on several small axisymmetric bodies and on the wall of a large supersonic tunnel was obtained.

NACA TN 4023

DESIGN AND EXPERIMENTAL EVALUATION OF A LIGHT-WEIGHT TURBINE-WHEEL ASSEMBLY. W. C. Morgan and R. H. Kemp. June 1957. 25p. diagrs., photos. (NACA TN 4023)

Light-weight design concepts were developed and tested in a full-scale turbine wheel with a tip diameter of 34.3 inches and a tip speed of 1190 feet per second. The rotor consisted of two thin disks attached to each other by spacers and bolts. Each disk was contoured for optimum stress distribution. The turbine blades were hollow castings with an integral serrated root. The total weight of the wheel, exclusive of the shafts and bolts, was 121 pounds. A disk serration segment failed after 6 hours and 46 minutes of engine operation. Failure was attributed to excessive blade vibration.

NACA TN 4024

APPRAISAL OF THE HAZARDS OF FRICTION-SPARK IGNITION OF AIRCRAFT CRASH FIRES. John A. Campbell. May 1957. 23p. photos., tabs. (NACA TN 4024)

A study was made to determine if common aircraft metals produce friction sparks capable of igniting combustibles that might be spilled in an airplane crash. Samples of aluminum, titanium, magnesium, chrome-molybdenum steel, and stainless steel were dragged over both concrete and asphalt runways while a combustible mixture of gasoline, JP-4 fuel, kerosene, or preheated oil was sprayed around the sample. No ignitions occurred from the sliding aluminum; but the titanium, magnesium, chrome-molybdenum steel, and stainless steel produced friction sparks that ignited the combustibles.

NACA TN 4025

THERMODYNAMIC STUDY OF A ROOTS COMPRESSOR AS A SOURCE OF HIGH-TEMPERATURE AIR. Clarence B. Cohen, Richard R. Woollett, and Kenneth C. Weston. June 1957. 34p. diagrs., tab. (NACA TN 4025)

Thermodynamic analysis of a Roots blower indicates that leakage of hot air from the high- to the low-pressure side produces a large preheating effect on the supply air. The resulting outlet temperatures are extremely sensitive to heat losses in the cycle. Calculations indicate that outlet temperatures of 7000° and 5000° R will result if the Stanton numbers, based on rotor tip speed, are 0.002 and 0.003, respectively.

NACA TN 4038

PERFORATED SHEETS AS THE POROUS MATERIAL FOR A SUCTION-FLAP APPLICATION. Robert E. Dannenberg, James A. Weiberg, and Bruno J. Gambucci. May 1957. 36p. diagrs., photos. (NACA TN 4038)

Two-dimensional tests were made of an NACA 0006 airfoil with area suction applied to a porous region on a 0.3-chord trailing-edge flap deflected 50°. The lift with suction approached the value computed from thin-airfoil theory. The lift gains and suction quantity requirements were unaffected by the perforation patterns of the surface over a wide range of hole sizes and spacings.

NACA TN 4049

INFLUENCE OF CRUCIBLE MATERIALS ON HIGH-TEMPERATURE PROPERTIES OF VACUUM-MELTED NICKEL-CHROMIUM-COBALT ALLOY. R. F. Decker, John P. Rowe, and J. W. Freeman, University of Michigan. June 1957. 34p. diagrs., photos., tabs. (NACA TN 4049)

A study of the effect of induction-vacuum-melting procedure on the high-temperature properties of a titanium-and-aluminum-hardened nickel-base alloy revealed that a major variable was the type of ceramic used as a crucible. Reactions between the melt and magnesia or zirconia crucibles apparently increased high-temperature properties by introducing small amounts of boron or zirconium into the melts. Heats melted in alumina crucibles had relatively low rupture life and ductility at 1,600° F and cracked during hot-working as a result of deriving no boron or zirconium from the crucible.

CURRENT NACA RESEARCH REPORTS

NACA TN 4051

EFFECTS OF RAPID HEATING ON STRENGTH OF AIRFRAME COMPONENTS. Richard A. Pride, John B. Hall, Jr., and Melvin S. Anderson. June 1957. 14p. diagrs., photos., tab. (NACA TN 4051)

Results of several experimental investigations are presented which indicate that thermal stresses reduce the bending load carried by beams and ring-stiffened cylinders at buckling. For beams that buckle locally, no apparent effect of thermal stress on the maximum load has been found. For beams that buckle in the wrinkling mode and for cylinders, a reduction in maximum load has been observed.

NACA TN 4052

TWO FACTORS INFLUENCING TEMPERATURE DISTRIBUTIONS AND THERMAL STRESSES IN STRUCTURES. William A. Brooks, Jr., George E. Griffith, and H. Kurt Strass. June 1957. 13p. diagrs. (NACA TN 4052)

The influence of joint conductivity and internal radiation on temperature distribution and thermal stresses has been discussed. Joints of poor conductivity can occur in normal fabrication procedure and greatly alter temperature distributions and increase thermal stresses. On the other hand, internal radiation tends to make the temperature distributions more uniform and thereby relieves thermal stress.

NACA TN 4053

THE COMBINATIONS OF THERMAL AND LOAD STRESSES FOR THE ONSET OF PERMANENT BUCKLING IN PLATES. George W. Zender and Richard A. Pride. June 1957. 10p. diagrs., photo. (NACA TN 4053)

A simple and practical method for evaluating the onset of permanent buckling in plates in the presence of combined thermal and compressive load stresses is outlined. A particular application of the method shows reasonable agreement with tests of 17-7 PH stainless-steel square tubes. The results indicate that the compressive load stress which the plate can support at the onset of permanent buckling is substantially reduced as the temperature difference of the plate and adjoining members increases.

NACA TN 4054

EFFECT OF TRANSIENT HEATING ON VIBRATION FREQUENCIES OF SOME SIMPLE WING STRUCTURES. Louis F. Vosteen, Robert R. McWithey, and Robert G. Thomson. June 1957. 10p. diagrs. (NACA TN 4054)

Thermal stresses, which may result from transient heating, can cause changes in the effective stiffness of wing structures. Some effects of this change in stiffness were investigated experimentally by radiantly heating three types of simple wing structures: a uniform plate, a solid double-wedge section, and a circular-arc multiweb-wing section. Changes in stiffness were determined by measuring the changes in natural frequency of vibration during transient heating. Some comparisons are made between theoretical calculations and the measured data.

NACA TN 4056

LOADS IMPLICATIONS OF GUST-ALLEVIATION SYSTEMS. William H. Phillips. June 1957. 11p. diagrs., tab. (NACA TN 4056)

A brief review is presented of the basic methods of gust alleviation. Some results obtained in flight tests of a gust-alleviation system are included.

NACA TN 4057

INVESTIGATION AT LOW SPEEDS OF DEFLECTORS AND SPOILERS AS GUST ALLEVIATORS ON A MODEL OF THE BELL X-5 AIRPLANE WITH 35° SWEPT WINGS AND ON A HIGH-ASPECT-RATIO 35° SWEPT-WING—FUSELAGE MODEL. Delwin R. Croom and Jarrett K. Huffman. June 1957. 37p. diagrs., tab. (NACA TN 4057)

Results of an investigation at low speeds to determine the gust-alleviation capabilities (reduction in lift-curve slope) of spoilers and deflectors on a 35° swept-wing model of high aspect ratio and on a 1/4-scale model of the X-5 airplane with 35° swept wings indicate that deflector and spoiler-deflector types of controls can be designed to provide considerable gust alleviation for a swept-wing airplane while still maintaining stability and control.

NACA TN 4060

A WIDE-FREQUENCY-RANGE AIR-JET SHAKER. Robert W. Herr. June 1957. 15p. diagrs. (NACA TN 4060)

This paper presents a description of a simple air-jet shaker. Its force can be calibrated statically and appears to be constant with frequency. It is relatively easy to use, and it has essentially massless characteristics. This shaker is applied to define the unstable branch of a frequency-response curve obtained for a nonlinear spring with a single degree of freedom.

THE HOT-WIRE ANEMOMETER FOR TURBULENCE MEASUREMENTS. PART III. B. Wise and D. L. Schultz. 1956. 71p. diagrs. ARC CP 275. (Ask for N-48706*)

Further investigation of the operation of the hot-wire anemometer has shown that there are only two systems which are both statically stable and capable of improving the frequency response. A description is given of further experiments which have been made to verify the theory of operation of the wire, using both radio-frequency and direct current heating. An analysis of some feedback systems is given, and it is shown how these techniques may be used in the measurement of turbulence at high air speeds.

TURBULENT DIFFUSER FLOW. B. S. Stratford. 1956. 64p. diagrs. ARC CP 307. (Ask for N-48714*)

Exact solutions are obtained for the equations of motion for flow which everywhere is just at the condition of separation. Application is limited to that part of a diffuser in which the velocity profile has reached a constant shape. Standard mixing length theory as developed by Prandtl is the basis of the solutions. The solutions yield the value of the critical angle of a diffuser for just avoiding flow separation; this value is proportional to the square of the turbulence level.

AERODYNAMIC DERIVATIVES FOR TWO CROPPED DELTA WINGS AND ONE ARROWHEAD WING OSCILLATING IN DISTORTION MODES. D. L. Woodcock. 1956. 69p. tabs. ARC CP 268. (Ask for N-48718*)

Aerodynamic derivatives are given for three particular plan forms oscillating with symmetric distortion modes in incompressible flow. The plan forms are: (1) a cropped delta wing of aspect ratio 3 and taper ratio 1/7, (2) a cropped delta wing of aspect ratio 1.2 and taper ratio 1/7, (3) an arrowhead wing of aspect ratio 1.32, taper ratio 7/18 and angle of sweep of 63.4^{o} at the quarter chord. The results are for modes of the form $/\eta/^{n}$ for $n = 0(1)4$ where η is a nondimensional spanwise coordinate. They have been determined from intermediate results which D. E. Lehrian had earlier obtained by the vortex lattice method. The results are compared, for some cases, with the corresponding values given by very low aspect-ratio theory.

TURBULENCE ENCOUNTERED BY VIKING AIRCRAFT OVER EUROPE. J. R. Heath-Smith. 1957. 15p. diagrs., tabs. ARC CP 311.
(Ask for N-48720*)

Accelerations in turbulence were recorded on B.E.A. Viking aircraft for 117,000 miles of flying over European routes during three years. The records show that the number of gusts decreases from sea level to 8000 feet. There is some evidence below 5000 feet that turbulence is greatest in spring and least in autumn. Average gust frequencies during climb and descent were twice those during cruise below 8000 feet and this is attributed to the pilot's discretion in the choice of cruising altitude.

A THEORETICAL INVESTIGATION OF THE FACTORS AFFECTING STALLING FLUTTER OF COMPRESSOR BLADES. A. D. S. Carter. 1956. 22p. diagrs. ARC CP 265. (Ask for N-48721*)

Recent work has drawn attention to the importance of the critical flutter velocity in applying cascade data to axial compressors. The hope has been expressed that it was primarily an aerodynamic phenomenon, though the possibility of mechanical damping being an important factor was not excluded. The mechanism of stalling flutter has been reexamined to establish, as far as is at present possible, the major parameters involved. On the basis of the hypothesis advanced, the factors governing the critical flutter velocity have been isolated. The variation of this velocity with respect to blade thickness has been deduced, and compared with test results. Agreement is good, but further work is necessary before the hypothesis can be accepted "in toto." Mechanical damping appears to be a major parameter, and may severely limit the practical application of the theoretical solution.

THE NUMERICAL INTEGRATION OF THE LAMINAR COMPRESSIBLE BOUNDARY LAYER EQUATIONS, WITH SPECIAL REFERENCE TO THE POSITION OF SEPARATION WHEN THE WALL IS COOLED. G. E. Gadd. 1957. 17p. tabs. ARC CP 312.
(Ask for N-48723*)

A method of integrating the laminar compressible boundary-layer equations is described. It is assumed that the external velocity at the leading edge of the boundary layer is not zero, but cases with leading-edge stagnation points could be dealt with on broadly similar lines. The method enables results of fair accuracy to be obtained even when large intervals of integration are used, and it is thus suitable where the computations are performed by means of a slide rule or mechanical computing machine. Certain solutions obtained by the method and concerned with the position of separation under adverse pressure gradients are presented.

FLUTTER CALCULATIONS ON A RESONANCE MODEL DELTA WING. H. Hall. 1956. 18p. diagrs. ARC CP 260. (Ask for N-48724*)

Resonance tests on a dural model delta wing are used as a basis for flutter calculations to determine the effect on the flutter characteristics of changes in structural inertias and stiffnesses. Forward movement of the inertia axis and increased stiffness of the wing spars are shown to be separately beneficial. The calculated flutter speeds are compared with flutter speeds given by formulas derived from earlier flutter tests on model delta wings in the wind tunnel and on ground-launched rockets. There is qualitative agreement on the effects of the structural changes, but the absolute values of flutter speed differ appreciably. Possible explanations for the differences are discussed.

BOUNDARY LAYER MEASUREMENTS ON 10° AND 20° CONES AT M = 2.45 AND ZERO HEAT TRANSFER. F. V. Davies and J. R. Cooke. 1956. 62p. diagrs., photos., tabs. ARC CP 264. (Ask for N-48728*)

Transition from laminar to turbulent flow occurred between 4 and 6 inches from the tip of the 10° cone at RN between 10^{6} and 1.4×10^{6}; the layer on the 20° cone was laminar over its entire length of 6 inches, that is, up to a RN of 1.4×10^{6}. Most of the laminar boundary-layer measurements were made on the 20° cone and results agree reasonably well with the flat-plate solution of Monaghan transformed by the theoretical cone flat-plate relations of Hantzsche and Wendt, and Mangler. All the data for the turbulent boundary layer were obtained from measurements made on the 10° cone and comparison with flat-plate data indicates that the cone flat-plate relation is within $\frac{6}{\sqrt{3}}$ percent of an empirical relation analogous to the $\sqrt{3}$ laminar boundary-layer factor.

THREE-DIMENSIONAL WIND-TUNNEL TESTS OF A 30° JET FLAP MODEL. J. Williams and A. J. Alexander. 1957. 49p. diagrs., photo. ARC CP 304. (Ask for N-48730*)

As a first investigation of finite aspect-ratio effects in relation to the jet flap scheme, pressure plotting experiments were made on a small-scale model, with a 12-1/2 percent thick wing section already tested under two-dimensional conditions at the N.G.T.E. The spanwise distribution of "pressure lift" loading induced by T.E. blowing was evaluated by chordwise integration of the surface static pressures, and followed closely that which would be expected for a conventional wing at incidence (without T.E. blowing). The total lift, drag, and pitching moments were derived for values of jet momentum coefficient C_J up to 2 at wing incidences between -5° and 20°, and up to 5 at zero incidence, by summing the corresponding integrated pressure forces and jet reaction components.

THE EFFECT ON TRANSITION OF ISOLATED SURFACE EXCRESCENCES IN THE BOUNDARY LAYER. PART I. N. Gregory and W. S. Walker, National Physical Laboratory. BRIEF FLIGHT TESTS ON A VAMPIRE I AIRCRAFT TO DETERMINE THE EFFECT OF ISOLATED SURFACE PIMPLES ON TRANSITION. D. Johnson, Royal Aircraft Establishment. 1956. 23p. diagrs., photos., tabs. ARC R & M 2779. Supersedes ARC 13,436, FM 1482, Perf. 698 & RAE Tech. Memo. Aero 210. (Ask for N-48741*)

The effect of isolated surface excrescences in a laminar boundary layer in producing disturbances which may lead to turbulent flow has been examined experimentally by several methods. Photographs of some of the flow patterns visualized by smoke and china clay techniques are given. The critical heights of roughness which just give rise to spreading wedges of turbulent flow have been measured on a flat plate and on two airfoils at several angles of incidence. Results are analyzed and presented in a form which enables estimates to be made of protuberances permissible on laminar-flow surfaces at full-scale flight RN.

PLASTIC STRAIN AND FRACTURE OF SINGLE-CRYSTALS AND POLYCRYSTALS OF METAL UNDER STATIC AND CYCLIC TORSION. (Plasticheskaia deformatsiia i razrushenie metallicheskikh poli- i monokristallov pri staticheskom i tsiklicheskom kruchenii). F. P. Rybalko. April 1957. 18p. diagr., photos. Translation from Fizika Metallov i Metallovedenie, v. 1, issue 2, 1955, p. 231-238. (Ask for N-53384*)

An investigation was made of plastic strain and fracture of cylindrical specimens, prepared of polycrystal copper, α-brass and zinc, and also single-crystals, bicrystals, and tricrystals of zinc, cadmium, and aluminum. It was established that the viscous fracture by torsion is preceded by a localization of the strain, in the shape of a zone which coincides, as to direction, with one of the principal shearing stresses; or in the shape of a system of zones parallel to it; or, finally, in the shape of two mutually perpendicular systems of zones of localized strain. The localization of the strain decreases with increase in the rate of strain and appears most perfectly under cyclic torsion. Fracture of metals, analogous to that of plexiglass occurs under the action of normal stresses.

NACA RM A50F13

AN EXPERIMENTAL INVESTIGATION AT LARGE SCALE OF AN NACA SUBMERGED INTAKE AND DEFLECTOR INSTALLATION ON THE REARWARD PORTION OF A FUSELAGE. Curt A. Holzhauser. August 30, 1950. 22p. diagrs., photos. (NACA RM A50F13)

Presented are the results of an experimental investigation in the Ames 40- by 80-foot wind tunnel of an NACA submerged intake and deflector installation on the rearward portion of the fuselage of a model. The entrance ram-recovery ratio of the intake was between 0 and 0.05 lower than that obtained with a similar, but smaller, intake located farther forward on a fuselage. The external drag of the intake approached zero at the higher mass-flow ratios.

NACA RM A53F16

INVESTIGATION OF THE NACA 1.167-(0)(03)-058 AND NACA 1.167-(0)(05)-058 THREE-BLADE PROPELLERS AT FORWARD MACH NUMBERS TO 0.92 INCLUDING EFFECTS OF THRUST-AXIS INCLINATION. Fred A. Demele and William R. Otey. August 1953. 61p. diagrs., photos., tabs. (NACA RM A53F16)

This report presents the aerodynamic characteristics of NACA 1.167-(0)(03)-058 and NACA 1.167-(0)(05)-058 three-blade propellers at Mach numbers to 0.92. The data include the effects of thrust-axis inclination on the performance of both propellers, the negative-thrust characteristics of the thick-blade propeller at low forward speeds, and the static-thrust characteristics of both propellers.

NACA RM A54F18

A COMPARISON OF THE LONGITUDINAL AERODYNAMIC CHARACTERISTICS AT MACH NUMBERS UP TO 0.94 OF SWEPTBACK WINGS HAVING NACA 4-DIGIT OR NACA 64A THICKNESS DISTRIBUTIONS. Fred B. Sutton and Jerald K. Dickson. August 1954. 67p. diagrs., tab. (NACA RM A54F18)

The investigation was conducted in the Ames 12-foot pressure wind tunnel with two twisted and cambered wings, identical in all respects except section. Sweepback was varied from 40° to 50°. The corresponding aspect ratios varied from 7 to 5. Tests were made at Reynolds numbers up to 10 million at low speed and at Mach numbers from 0.25 to 0.94 at a Reynolds number of 2 million.

NACA RM A54F21

FLIGHT INVESTIGATION OF THE EFFECTS OF HORIZONTAL-TAIL HEIGHT, MOMENT OF INERTIA, AND CONTROL EFFECTIVENESS ON THE PITCH-UP CHARACTERISTICS OF A 35° SWEPT-WING FIGHTER AIRPLANE AT HIGH SUBSONIC SPEEDS. Norman M. McFadden and Donovan R. Heinle. January 1955. 24p. diagrs., photos., tab. (NACA RM A54F21)

The pitch-up and buffet characteristics of a YF-86D airplane with two horizontal-tail configurations are compared over a Mach number range of 0.70 to 0.91. Results of calculations are presented which correlate the differences in pilots' opinions of the pitch-up for the YF-86D and F-86A with the differences in control effectiveness and moment of inertia of the two airplanes.

NACA RM A55I15

A METHOD FOR SIMULATING THE ATMOSPHERIC ENTRY OF LONG-RANGE BALLISTIC MISSILES. A. J. Eggers, Jr. December 1955. 19p. diagr. (NACA RM A55I15)

It is demonstrated with the aid of similitude arguments that a model fired from a hypervelocity gun upstream through a special supersonic nozzle should undergo motion and experience aerodynamic heating and resulting thermal stresses like those encountered by a long-range ballistic missile entering the earth's atmosphere. This combination of hypervelocity gun and supersonic nozzle is therefore termed an "Atmospheric Entry Simulator."

NACA RM E9F01

EXPERIMENTAL PERFORMANCE OF CHLORINE TRIFLUORIDE - HYDRAZINE PROPELLANT COMBINATION IN 100-POUND-THRUST ROCKET ENGINE. Paul M. Ordin and Riley O. Miller. August 15, 1949. 22p. diagrs., photos. (NACA RM E9F01)

Values of specific impulse, volume specific impulse, heat rejection, nozzle thrust coefficient, and characteristic velocity were determined over range of mixture ratios using chlorine trifluoride - hydrazine propellant combination in 100-pound-thrust rocket engine. Maximum measured values were specific impulse, 234 pound-seconds per pound and characteristic velocity 5590 feet per second. Maximum performance values corrected for heat rejection were 247 pound-seconds per pound for specific impulse, 349 x 62.4 pound-seconds per cubic foot for volume specific impulse. Maximum values occurred at approximately 33 percent fuel by weight. Average nozzle thrust coefficient was 1.34.

NACA RM E51C26

COMBUSTION PERFORMANCE EVALUATION OF MAGNESIUM-HYDROCARBON SLURRY BLENDS IN A SIMULATED TAIL-PIPE BURNER. Leonard K. Tower and J. Robert Branstetter. May 15, 1951. 53p. diagrs., photos., tabs. (NACA RM E51C26)

An experimental investigation was conducted on a 6-inch simulated tailpipe burner to determine the performance characteristics of magnesium-hydrocarbon slurries at sea-level conditions. The combustion stability of slurries with high magnesium concentration showed large improvements over the reference hydrocarbon fuel (MIL-F-5624). Compared to the reference hydrocarbon, slurries containing 30 and 60 percent magnesium produced a 15- and 51-percent increase in net tailpipe thrust, respectively, corresponding to 5 and 14 percent increase in air specific impulse.

NACA RM E51D23

STATUS OF COMBUSTION RESEARCH ON HIGH-ENERGY FUELS FOR RAM JETS. Walter T. Olson and Louis C. Gibbons. October 1951. 75p. diagrs., photos., tabs. (NACA RM E51D23)

A review has been made of the present status of research and development on high-energy fuels for ram jets. Fuels considered include aluminum, boron, boron hydrides, carbon, coal, coal and metal compositions, liquid hydrogen, and magnesium. Theoretical potentialities of the fuels are presented along with a summary of experimental combustion data from 12 investigators.

NACA RM E52A23

PREPARATION AND PHYSICAL PROPERTIES OF METAL SLURRY FUELS. James B. Gibbs and Preston N. Cook, Jr. March 1952. 36p. diagrs., photos., tabs. (NACA RM E52A23)

A preliminary investigation was conducted to determine the physical properties of slurries and the use of a metal-soap additive to prepare stable slurries of commercial magnesium, aluminum, and boron powders in a MIL-F-5624 grade JP-3 base fuel. Several of the prepared slurries have physical properties acceptable for combustion-research evaluation and limited flight use.

NACA RM E52B01

AN EXPERIMENTAL INVESTIGATION OF THE COMBUSTION PROPERTIES OF A HYDROCARBON FUEL AND SEVERAL MAGNESIUM AND BORON SLURRIES. Albert M. Lord. April 1952. 30p. diagrs. (NACA RM E52B01)

The combustion products of several magnesium and boron slurries were analyzed to explore the characteristics of metal-hydrocarbon combustion over a range of fuel-air ratios and to determine how the metal and hydrocarbon separately contribute to the overall combustion.

NACA RM E52F04

EXPERIMENTAL INVESTIGATION OF A TWO-DIMENSIONAL SPLIT-WING RAM-JET INLET AT MACH NUMBER OF 3.85. James F. Connors and Richard R. Woollett. August 1952. 28p. diagrs., photos. (NACA RM E52F04)

Performance characteristics of a two-dimensional isentropic diffuser have been experimentally determined at a Mach number of 3.85. At zero angle of

attack, a maximum total-pressure recovery of 0.41 was obtained with a supercritical mass-flow ratio of 0.95. As a consequence of the twin-duct arrangement of the diffuser, a large discontinuity in pressure recovery and mass flow with a characteristic hysteresis was encountered between critical and subcritical operation. An asymmetric shock pattern with large-scale separation and flow reversal in one of the passages occurred at reduced mass flows. Pressure and force data are presented for an angle-of-attack range from zero to 4°.

NACA RM E52F16

INFLUENCE OF A CANARD-TYPE CONTROL SURFACE ON THE INTERNAL AND EXTERNAL PERFORMANCE CHARACTERISTICS OF NACELLE-MOUNTED SUPERSONIC DIFFUSERS (CONICAL CENTERBODY) AT A REARWARD BODY STATION FOR A MACH NUMBER OF 2.0. L. J. Obery and H. S. Krasnow. August 1952. 24p. diagrs. (NACA RM E52F16)

An investigation was conducted in the Lewis 8- by 6-foot supersonic wind tunnel at a Mach number of 2.0 to determine the effects of the wake resulting from a canard control surface on diffuser performance and on the engine-body favorable interference drag. Nacelle-type engines were mounted on a body of revolution approximately 10 mean chords downstream of and in the plane of the canard surface. Severe performance reductions resulted when the inlet was alined with the canard surface tips; however, these reductions could be considerably mitigated by a rather small outboard shift of the diffusers. At the higher angles of attack, the body upwash field adversely affected the diffuser performance. The engine-body interference drag was not changed measurably by the canard-surface wake.

NACA RM E52K12

EFFECT OF PARTICLE SIZE AND STABILIZING ADDITIVES ON THE COMBUSTION PROPERTIES OF MAGNESIUM SLURRY. Albert M. Lord and Vernida E. Evans. January 1953. 28p. diagrs., photos. (NACA RM E52K12)

An experimental investigation was conducted with a 1-7/8 inch diameter burner to determine the effects of particle size and of stabilizing additives on the combustion performance of magnesium-hydrocarbon slurry fuels. The fuels tested were MIL-F-5624-A grades JP-3 and JP-4 and slurries of magnesium in JP-3 fuel. A slurry composed of 4-1/2 micron magnesium particles had a leaner mixture limit at which a flame could be maintained and a maximum blowout velocity much higher than a slurry composed of 20-micron particles. The combustion efficiency of the metal in the 4-1/2 micron slurry was consistently higher than in the 20-micron slurry in spite of its being burned at a much higher burner-inlet velocity. The slurries stabilized with petrolatum had combustion efficiencies and blowout velocities comparable with those of the gel-stabilized slurries.

NACA RM E53D30

EXPERIMENTAL INVESTIGATION OF PHYSICAL AND COMBUSTION PROPERTIES OF SEVERAL RESIDUAL FUEL OILS AND MAGNESIUM - FUEL-OIL SLURRIES IN A RAM-JET-TYPE COMBUSTOR. Preston N. Cook, Jr., Vernida E. Evans, and Erwin A. Lezberg. June 1953. 23p. diagrs., photos., tab. (NACA RM E53D30)

An experimental investigation was conducted with a 1-7/8 inch diameter burner to determine the suitability of residual fuel oils as carriers in magnesium slurries. The residual-fuel-oil slurries were compared to slurries containing MIL-F-5624A grade JP-4 fuel stabilized with petrolatum or gel with respect to combustion efficiency, blowout velocity, and stability of the magnesium-hydrocarbon suspension. Four residual fuel oils having viscosities of 5 to 415 centipoises were investigated by themselves and in slurries of 50 percent magnesium having viscosities from 22 to 8050 centipoises. The blowout velocities of the fuel-oil slurries were lower than those of the petrolatum- or gel-stabilized JP-4 slurries. Fuel-oil slurries containing 2-micron powder had much higher blowout velocities than fuel-oil slurries made with 13-micron powder. All the 13-micron-magnesium-powder slurries with fuel oil or JP-4 carriers had substantially the same metal and hydrocarbon combustion efficiencies over a range of equivalence ratios. The 2-micron-powder slurry, although burned at four times the inlet air velocity of the 13-micron-powder slurries, showed a slightly higher metal combustion efficiency. Neither the fuel oils by themselves nor the slurries made with the two lower viscosity oils required preheating for combustion using the air atomizing nozzle, while the slurries made with the two more viscous fuel oils could be burned only when preheated to a temperature approaching 212° F. Slurries made with 2-micron powder in each of the fuel oils and with 13-micron powder in the two more viscous fuel oils were sufficiently stable to be usable for at least 48 hours. Slurries made with the 13-micron powder in the two lower viscosity oils were unstable; that is, they settled out within 48 hours and needed agitation before they could be used.

NACA RM E53E27

MAGNESIUM-SLURRY COMBUSTION PERFORMANCE IN 6.5-INCH-DIAMETER RAM-JET ENGINE MOUNTED IN CONNECTED-PIPE FACILITY. J. Robert Branstetter, James B. Gibbs, and Warner B. Kaufman. August 1953. 63p. diagrs., photos., tabs. (NACA RM E53E27)

The combustion performance of slurry type fuels, consisting of 50 percent magnesium powder in a hydrocarbon carrier, has been investigated in a flight-type, 6.5-inch-diameter ram-jet engine in a connected-pipe facility. A combustor configuration, deemed suitable for short-range flight applications, has been developed that provides acceptable and reproducible combustion performance over the full range of equivalence ratio investigated, from 0.40 to 0.95.

NACA RM E53F11

PERFORMANCE COMPARISON OF THREE CANARD-TYPE RAM-JET MISSILE CONFIGURATIONS AT MACH NUMBERS FROM 1.5 TO 2.0. Evan A. Fradenburgh and Emil J. Kremzier. August 1953. 31p. diagrs., tabs. (NACA RM E53F11)

Performance characteristics of three canard-type ram-jet missiles were investigated at Mach numbers from 1.5 to 2.0 to obtain a performance comparison. The investigation covered a range of angle of attack, control surface deflection angle, and engine mass-flow ratio. The missiles were similar except for their engine installations, two of which were twin-engine nacelle-type and the third, a fuselage scoop type. Range comparisons indicated approximately comparable ranges for the scoop type and the wing-mounted nacelle-type installations, that of the scoop type being slightly greater. The nacelle type with engines strut-mounted in a vertical plane through the fuselage center line had the shortest range.

NACA RM E53F17

METHOD FOR ESTIMATING COMBUSTION EFFICIENCY AT ALTITUDE FLIGHT CONDITIONS FROM COMBUSTOR TESTS AT LOW PRESSURES. Walter T. Olson, J. Howard Childs, and Wilfred E. Scull. August 1953. 15p. diagrs. (NACA RM E53F17)

The development and the use of a chart for use in estimating the combustion efficiency of a turbojet at altitude flight conditions are described. Use of the chart requires that the following data be available for the particular combustor and turbojet engine under consideration: (1) The combustion efficiency must be known from tests of the combustor over a range of conditions to determine the correlation curve of efficiency against the parameter $V_r/p_i t_i$ (where V_r is a combustor reference velocity and p_i and t_i are the pressure and temperature at the combustor inlet). These combustor tests need not be conducted at conditions simulating the flight conditions of interest. (2) The sea-level, static performance of the turbojet engine must be known to determine the air-flow rate, compressor pressure ratio, and turbine-inlet temperature at various engine speeds. The combustion efficiency chart is based on the assumption that the corrected gas flows, pressures, and temperatures of engine components other than the combustor are unique functions of corrected engine speed. The validity of the chart is dependent, of course, on the validity of the correlation of combustion efficiency with the parameter $V_r/p_i t_i$, and this correlation is subject to the limitations discussed in this report.

NACA RM E53J16

STUDY OF THE PHYSICAL PROPERTIES OF PETROLATUM-STABILIZED MAGNESIUM-HYDROCARBON SLURRY FUELS. Murray L. Pinns and Irving A. Goodman. January 1954. 58p. diagrs., tabs. (NACA RM E53J16)

Magnesium-hydrocarbon slurries containing a moderate proportion of petrolatum have physical properties such that they offer promise as experimental aircraft fuels. The settling of the magnesium is greatly retarded by the petrolatum, and the slurries can easily be remixed to their original condition after storage. Successive batches which have closely similar properties can be prepared readily. The apparent viscosity of these slurries increased rapidly with increasing magnesium concentration, with increasing petrolatum concentration, and with decreasing temperature. As the apparent viscosity increased, the extent of settling and the ease of remixing both decreased. Although no quantitative correlation was found between the properties of the slurry and those of the petrolatum, and no one petrolatum gave slurries which were best in all respects, one of the five petrolatums used was judged to be superior to the others.

NACA RM E53K05

STARTING CHARACTERISTICS AND COMBUSTION PERFORMANCE OF MAGNESIUM SLURRY IN 6.5-INCH-DIAMETER RAM-JET ENGINE MOUNTED IN CONNECTED-PIPE FACILITY. James B. Gibbs. January 1954. 25p. diagrs., tabs. (NACA RM E53K05)

The starting characteristics and combustion performance of slurry type fuels, consisting of 50 percent magnesium powder in a hydrocarbon carrier, have been investigated in a flight-type, 6.5-inch-diameter ram-jet engine in a connected-pipe facility. Quick, dependable starting of the engine was obtained by the use of a disk which blocked part of the combustor area downstream of the flame holder. Acceptable performance was achieved with a short fuel-air mixing length by the development of a fuel-distribution control sleeve.

NACA RM E53K23

A PRELIMINARY STUDY OF THE PREPARATION OF SLURRY FUELS FROM VAPORIZED MAGNESIUM. Walter R. Witzke, George M. Prok, and Thomas J. Walsh. February 1954. 21p. diagrs., photos., tabs. (NACA RM E53K23)

Slurry fuels containing extremely small particles of magnesium were prepared by concentrating the dilute slurry product resulting from the shock-cooling of magnesium metal vapors with a liquid hydrocarbon spray. A complete description of the equipment and procedure used in preparing the fuel is given.

DECLASSIFIED NACA RESEARCH REPORTS

Ninety-five percent by weight of the solid particles formed by this process passed through a 100-mesh screen. The particle-size distribution of the screened fraction of one run, as determined by sedimentation analysis, indicated that 73 percent by weight of the metal particles were finer than 2 microns in equivalent spherical diameter. The purity of the solid particles ranged as high as 98.9 percent by weight of free magnesium. The screened product was concentrated by means of a bowl-type centrifuge from 0.5 to more than 50 percent by weight solids content to form an extremely viscous, clay-like mass. By the addition of a surface active agent, this viscous material was converted into a pumpable slurry fuel.

NACA RM E53L09

STUDY OF SOME DIELECTRIC PROPERTIES OF SUSPENSIONS OF MAGNESIUM PARTICLES IN MINERAL OIL. Aubrey P. Altshuller. February 1954. 42p. diagrs., photo., tabs. (NACA RM E53L09)

The variation of dielectric constant has been measured as a function of the concentration of magnesium particles; the shape, size, and degree of oxidation of the particles; the temperature; and the frequency of oscillation. The variation of dielectric constant and settling rate was investigated as a function of time. Also investigated were the effects of particle concentration, shape, and time on dielectric losses.

NACA RM E54A22

THE EFFECT OF MAGNESIUM PARTICLES OF VARIOUS EQUIVALENT DIAMETERS ON SOME PHYSICAL PROPERTIES OF PETROLATUM-STABILIZED MAGNESIUM-HYDROCARBON SLURRIES. Joseph M. Lamberti. April 1954. 48p. diagrs., photos., tabs. (NACA RM E54A22)

The effect of magnesium particles of various equivalent diameters on the apparent viscosity, sedimentation ratio, and redispersibility of petrolatum-stabilized magnesium - JP-4 slurries is described. The investigation was conducted by use of laboratory-scale apparatus. Powders of the following equivalent diameters were investigated: 2.8, 3.7, 7.2, 9.3, 12.0, and 14.8 microns. Data are also presented showing the effect of various magnesium concentrations on these physical properties.

NACA RM E54A28

BLOW-OUT VELOCITIES OF VARIOUS PETROLEUM, SLURRY, AND HYDRIDE FUELS IN A 1-7/8 INCH DIAMETER COMBUSTOR. Preston N. Cook, Jr., Albert M. Lord, and Samuel Kaye. April 1954. 20p. diagrs., tab. (NACA RM E54A28)

A 1-7/8 inch inside-diameter combustor has been developed which can be used to measure and compare the blowout velocities of single-component fuels, slurries, and fuel mixtures having a wide range of reactivity and physical properties. The blowout velocities of isooctane, n-heptane, isopentane, allyl chloride, and propylene oxide varied in the same way as the flame speeds of these fuels determined by the Bunsen flame method. The blowout velocity of 50 percent 1.5-micron magnesium slurry was much higher than that of the 50-percent 15-micron magnesium slurry. The blowout velocity of JP-4 was not increased by the addition of 50 percent boron. However, the addition of 3 percent pentaborane in JP-4 substantially increased its blowout velocity, and 40 percent pentaborane in JP-4 had a blowout velocity that approached that of 50 percent 1.5-micron magnesium slurry.

NACA RM E54C10

STABILIZATION OF 50-PERCENT MAGNESIUM - JP-4 SLURRIES WITH SOME ALUMINUM SOAPS OF C_8 ACIDS. Robert M. Caves. May 1954. 48p. diagrs., tabs. (NACA RM E54C10)

The effect of soap concentration on the gelling properties and stabilizing ability of three aluminum di-soaps of C_8 acids was investigated in small batches of slurry which consisted of 50 percent magnesium of 15-micron average particle size and MIL-5624A, grade JP-4 fuel. Each of the soaps at low concentrations (< 1 percent) was found to gel the slurry satisfactorily and reproducibly, and the best soap gave increased useful life to a slurry with increasing soap concentration. The overall useful life was greatly extended by regelling the slurry with an additional small quantity of soap. The best soap was also used satisfactorily in gelling larger (100 lb) batches of slurry. The physical properties measured were apparent viscosity at low rate of shear and, in a few cases, apparent viscosity at high rates of shear.

NACA RM E54D07

PERFORMANCE OF SLURRIES OF 50 PERCENT BORON IN JP-4 FUEL IN 5-INCH RAM-JET BURNER. Thaine W. Reynolds and Donald P. Haas. June 1954. 31p. diagrs., photos., tabs. (NACA RM E54D07)

The combustion performance of slurries of 50 percent boron in MIL-F-5624A grade JP-4 fuel was evaluated in a 5-inch connected-pipe ram-jet burner. It was necessary to use can-type flame holders to obtain an adequate piloting region for the slurry fuel. Higher heat outputs were obtained with slurry fuel than with JP-4 fuel alone but at higher fuel-air ratios. The combustion efficiency with slurry fuel dropped rapidly at leaner-than-stoichiometric fuel-air ratios, indicating low reactivity. High wall temperatures and increased burner length had little effect on heat output with boron slurry fuel; combustion smoothness was aided by high wall temperatures, however. Performance data are presented for several can-type flame holders. A maximum combustion efficiency of 89 percent for the slurry fuel was obtained at an equivalence ratio of 1.

HIGH-TEMPERATURE LUBRICANTS AND BEARINGS FOR AIRCRAFT TURBINE ENGINES. NACA Subcommittee on Lubrication and Wear. APPENDIX A: HIGH-SPEED AIRCRAFT MISSIONS. C. M. Michaels, Wright Air Development Center. APPENDIX B: ENGINE DESIGN TRENDS AFFECTING LUBRICANTS AND BEARINGS. C. C. Singleterry, Bureau of Aeronautics, Department of the Navy. APPENDIX C: PROBLEMS ENCOUNTERED AT HIGH TEMPERATURES IN LUBRICATION SYSTEMS OF TURBINE ENGINES. G. P. Townsend, Westinghouse Electric Corp. APPENDIX D: TURBOPROP GEAR LUBRICATION PROBLEMS. C. J. McDowall, General Motors Corp. APPENDIX E: NOTES ON HIGH-TEMPERATURE FLUIDS AND LUBRICANTS. E. E. Klaus and M. R. Fenske, Pennsylvania State College. APPENDIX F: NACA RESEARCH ON LUBRICANTS, BEARINGS, AND LUBRICATION FOR HIGH-TEMPERATURE TURBINE ENGINES. R. L. Johnson and E. E. Bisson. APPENDIX G: HIGH-TEMPERATURE BEARING PROBLEMS. F. W. Wellons. July 1954. (i), 101p. diagrs., photos., tabs. (NACA RM E54D27)

The problems, research status, and future possibilities for high-temperature lubricants and bearings for aircraft turbine engines are discussed. Higher operating temperatures are inevitable for bearings and lubricants. Liquid lubricants may be usable at high temperatures in closed lubrication systems. At 1000° F, where liquid lubricants may not be useful, solids and gases show promise. Tool steels show promise for high-temperature bearings.

NACA RM E54F14

EXPERIMENTAL DETERMINATION OF AERODYNAMIC FORCES NORMAL TO THE CHORD DUE TO ROTATING STALL ACTING ON COMPRESSOR BLADING. Donald F. Johnson and Eleanor L. Costilow. August 1954. 27p. diagrs., photos. (NACA RM E54F14)

The blade force variation due to flow fluctuations caused by rotating stall was investigated in a single-stage axial-flow compressor of 0.9 hub-tip ratio. Blade forces were determined from calibrated wire-resistance strain gages and flow fluctuations by hot-wire anemometers. The amplitude of the stator force variation equalled the maximum stator steady-state force. The amplitude of the oscillatory force on the guide vanes was two to three times the steady-state force at the maximum flow between stall zones.

NACA RM E54F17a

NOTE ON PERFORMANCE OF AIRCRAFT EJECTOR NOZZLES AT HIGH SECONDARY FLOWS. Fred D. Kochendorfer. August 1954. 20p. diagrs. (NACA RM E54F17a)

Theoretical considerations have shown that for an ejector having a convergent shroud the maximum weight-flow ratio and ejector pressure ratio which permit operation with a choked primary nozzle can be much less than the corresponding values for a cylindrical ejector, the discrepancy increasing for larger amounts of convergence. Comparison of experimental results with those of a simple one-dimensional analysis indicated good agreement for the value of the maximum weight-flow ratio and for the slope of the discharge coefficient curve, but only fair agreement for values of ejector pressure ratio.

NACA RM E54F18a

PREPARATION AND PROPERTIES OF CONCENTRATED BORON-HYDROCARBON SLURRY FUELS. Irving A. Goodman and Virginia O. Fenn. August 1954. 35p. diagrs., photos., tabs. (NACA RM E54F18a)

Fluid slurry fuels were prepared containing 50 to 60 percent boron powder of 1-micron average particle size in JP-4 and JP-5 fuels. The boron-hydrocarbon mixtures were fluidized with glycerol sorbitan laurate and stabilized with aluminum octoate. Satisfactory stability up to 6 months was observed for some slurries. Apparent viscosities changed with time, were higher for JP-5 slurries, decreased with increasing glycerol sorbitan laurate concentrations, increased with increasing boron and aluminum octoate concentrations, and were considerably lowered in the presence of acid traces.

NACA RM E54K22a

EFFECT OF SURFACE-ACTIVE ADDITIVES ON PHYSICAL BEHAVIOR OF 50-PERCENT SLURRIES OF 1.5-MICRON MAGNESIUM IN n-DECANE. Murray L. Pinns. February 1955. 54p. diagrs., photo., tabs. (NACA RM E54K22a)

The concentration and molecular structure of the additive, the presence of moisture, and the characteristics of the magnesium powder controlled the viscosity of the slurry. Other factors were the temperature and age of the slurry. The more fluid the slurry was made by the additive, the more the magnesium tended to settle and to form a hard cake. The additives that yielded the most fluid slurries had a hydroxly group together with one or more ester, metal salt, or polyoxyethylene groups in the molecule. Additives having only one of these types of polar group per molecule gave slurries that were less fluid. Suggestions are made regarding application of the results obtained, and a mechanism is proposed to explain some of the observed phenomena.

NACA RM E54L27a

BLOW-OUT VELOCITIES OF SEVERAL SLURRY AND LIQUID FUELS IN A 1-7/8 INCH DIAMETER COMBUSTOR. James F. Morris, Robert M. Caves, and Albert M. Lord. February 1955. 12p. diagrs., tab. (NACA RM E54L27a)

Blowout velocities of four slurries and three liquid fuels were determined in a 1-7/8 inch diameter combustor. Neohexane and a slurry containing 60 percent, 18-micron magnesium in neohexane had the same blowout limits. A slurry containing 60-percent,

DECLASSIFIED NACA RESEARCH REPORTS

18-micron magnesium in propylene oxide yielded blowout velocities substantially greater than those for propylene oxide fuel. A slurry produced by quenching vaporized magnesium with JP-4 fuel demonstrated a reactivity greater than that of any slurry previously evaluated in this combustor.

NACA RM E55B02

PERFORMANCE OF PURE FUELS IN SINGLE J33 COMBUSTORS. II - HYDROCARBON AND NON-HYDROCARBON FUELS. Arthur L. Smith and Jerrold D. Wear. April 1955. 63p. diagrs., photos., tabs. (NACA RM E55B02)

Investigations of the pure fuels - isooctane, n-pentane, isopentane, 2,2-dimethylbutane, pentene-2, methanol, propylene oxide, diethyl ether, acetone, carbon disulfide, acrolein, acrylonitrile, and butylsilane - were conducted in a J33 single combustor at several inlet-air conditions to determine a possible relation between combustor performance and fuel properties. Combustion efficiency at a constant heat-input value was correlated approximately by the parameter $u_x/L_v^{1/3}$, where u_x is the maximum burning velocity and L_v is the latent heat of vaporization. The data exhibited a slight trend toward an increase in maximum temperature rise with maximum burning velocity.

NACA RM E55B14

NACA RESEARCH ON SLURRY FUELS THROUGH 1954. Walter T. Olson and Roland Breitwieser. (Presented orally to Office of Naval Research (Pasadena) and NACA Subcommittee on Combustion in December 1954) April 1955. 30p. diagrs., photos. (NACA RM E55B14)

NACA research on slurry fuels (high-concentration suspensions of powdered metals in hydrocarbons) has included slurries of boron for greater flight range and of magnesium for greater thrust than is possible with hydrocarbons alone. Although slurries that are stable and fluid enough for research have been made, their physical properties are not yet good enough for use in aircraft. Combustion tests, mostly small-scale, show poor performance for boron, and excellent performance for magnesium.

NACA RM E55D01

PREPARATION AND HANDLING OF MAGNESIUM-HYDROCARBON SLURRIES FOR JET-ENGINE APPLICATIONS. Henry C. Barnett, A. M. Lord, and P. H. Wise. June 1955. 60p. diagrs., photos., tabs. (NACA RM E55D01)

In order to provide a summary of NACA slurry research, details of magnesium - jet-fuel slurry preparation, physical properties, storage, experimental fuel systems, disposal of solid combustion products, flammability hazards, and physiological hazards are discussed. The influence of additives and metal properties on slurry preparation and physical properties such as stability, viscosity, and density is discussed. Types of valves, pumping devices, and instrumentation are included in the discussion of experimental fuel systems for slurries.

NACA RM E55E17

PREPARATION OF 50 PERCENT BORON-HYDROCARBON SLURRIES USING COMBINATIONS OF GLYCEROL SORBITAN LAURATE WITH VARIOUS THICKENERS. Irving A. Goodman and Virginia O. Fenn. July 1955. 30p. diagrs., tab. (NACA RM E55E17)

Fluid slurries were prepared containing 50 percent boron powder of 1-micron average particle size in JP-5 fuel. Combinations of glycerol sorbitan laurate (as a fluidizing agent) with each of seven different commercial products (as thickening agents) were studied over a range of concentrations. Brookfield apparent viscosities were measured. The various additive formulations were evaluated on the basis of these viscosities as well as the settling characteristics and general physical appearance of the slurries containing these additives.

NACA RM E55E19

EFFECT OF TEMPERATURE ON VISCOSITY OF SLURRIES OF BORON AND MAGNESIUM IN JP-5 FUEL. Harold F. Hipsher. July 1955. 20p. diagrs., tabs. (NACA RM E55E19)

The viscosities for slurries containing 50 to 65 percent by weight of boron in JP-5 fuel were determined at temperatures from 30° to 80° C (86° to 176° F), and for slurries containing 50 percent magnesium in JP-5 from -40° to 80° C (-40° to 176° F). Plastic viscosities of the boron slurries as calculated from Severs Rheometer and Stormer viscometer data decreased consistently with an increase in temperature. An exponential curve of the form $\log y = aT + b$ fits the viscosity-temperature relation for the magnesium slurries from about 0° to 80° C, but does not fit the data below 0° C. The plastic viscosity and yield value of the magnesium slurries decreased with increasing temperature.

NACA RM E55F02

SOME DIELECTRIC PROPERTIES OF SUSPENSIONS OF BORON POWDERS IN MINERAL OIL. Aubrey P. Altshuller. August 1955. 21p. diagrs., tabs. (NACA RM E55F02)

The dielectric constant for suspensions of two types of boron powder in mineral oil was measured as a function of concentration of boron particles, moisture content, temperature, and frequency of oscillation. The effects of boron-powder concentration and moisture content on the dielectric loss (dissipation factor) also were investigated.

NACA RM E55F06

APPLICATION OF STREAM-FILAMENT TECHNIQUES TO DESIGN OF DIFFUSER BETWEEN COMPRESSOR AND COMBUSTOR IN A GAS-TURBINE ENGINE. Norbert O. Stockman. August 1955. 15p. diagrs. (NACA RM E55F06)

A rapid design method based on stream-filament techniques was developed and used to obtain the boundaries of an annular combustor-inlet diffuser from a given stagnation streamline, given boundaries of the combustor liner, and given inlet and terminal velocities.

NACA RM E55F08

PERFORMANCE OF INCONEL 550 TURBINE BLADES IN A TURBOJET ENGINE AND EFFECTS OF DIFFERENT FORGING TEMPERATURES AND HEAT TREATMENTS. C. A. Gyorgak, J. R. Johnston, and J. W. Weeton. August 1955. 55p. diagrs., photos., tabs. (NACA RM E55F08)

An investigation was made to determine effects of two forging temperatures and several heat treatments on engine performance of Inconel 550 turbine blades. Best performance was associated with a forging and solution temperature of 2150° F. Reducing either the forging or solution temperature to 1950° F reduced blade life. Reducing the forging temperature to 1950° F if the solution temperature is above 2100° F appears less damaging than reducing the solution temperature to 1950° F after forging at 2150° F.

NACA RM E55H26

EFFECT OF SURFACE-ACTIVE ADDITIVES ON PHYSICAL PROPERTIES OF SLURRIES OF VAPOR-PROCESS MAGNESIUM. Murray L. Pinns. November 1955. 22p. diagrs., photos., tabs. (NACA RM E55H26)

The presence of 3 to 5 percent surface-active additive gave the lowest Brookfield apparent viscosity, plastic viscosity, and yield value that were obtained for slurry fuels containing approximately 50 percent vapor-process magnesium in JP-1 fuel. The slurries settled little and were easily remixed. A polyoxyethylene dodecyl alcohol was the most effective of 13 additives tested in reducing the Brookfield apparent viscosity and the yield value of the slurry. The seven most effective additives all had a hydroxyl group plus an ester or polyoxethylene group in the molecule. The densities of some of the slurries were measured.

NACA RM E55K04a

PERFORMANCE OF PURE FUELS IN A SINGLE J33 COMBUSTOR. III - FIVE HYDROCARBON GASEOUS FUELS AND ONE OXYGENATED-HYDROCARBON GASEOUS FUEL. Arthur L. Smith and Jerrold D. Wear. February 1956. 36p. diagrs., tabs. (NACA RM E55K04a)

The gaseous fuels propane, ethane, ethylene, acetylene, 1,3-butadiene, and ethylene oxide were investigated using a J33 single combustor at several inlet-air conditions to determine relations between combustor performance and fuel properties. Combustion efficiency at a constant heat-input value increased at the more severe operating conditions with an increase in maximum burning velocity, an increase in flammability range, and a decrease in minimum spark-ignition energy. Combustion efficiency was altered when the injection of the gaseous fuel in the primary combustion zone was varied by changing fuel-injector design.

NACA RM E55K24

EXPERIMENTAL INVESTIGATION OF TURBINE STATOR-BLADE-OUTLET BOUNDARY-LAYER CHARACTERISTICS AND A COMPARISON WITH THEORETICAL RESULTS. Warren J. Whitney, Warner L. Stewart, and James W. Miser. March 1956. 24p. diagrs. (NACA RM E55K24)

The boundary-layer momentum thickness for the blade, as well as for the two surfaces individually, was in reasonably close agreement with the theoretical values. The boundary-layer form, pressure, and energy factors could be satisfactorily approximated by a simple power-law velocity profile having an exponent of 1/7. The trend of the experimental values of boundary-layer momentum thickness as a function of blade-outlet critical-velocity ratio was similar to the theoretical curve, verifying to some extent the effect of Reynolds and Mach numbers that was assumed in theory.

NACA RM E56J19a

EFFECT OF PLASTIC VISCOSITY AND YIELD VALUE ON SPRAY CHARACTERISTICS OF MAGNESIUM-SLURRY FUEL. George M. Prok. January 1957. 23p. diagrs., photo., tabs. (NACA RM E56J19a)

Magnesium slurries were sprayed onto a sheet of paper from an air-atomizing injector. Drop sizes and distributions were then determined from photomicrographs. Four different surface-active additives were used in preparing the slurries to give plastic viscosities between 0.22 and 0.51 poise and yield values between 150 and 810 dynes-cm^2. It was found that there was no significant variation in the spray characteristics of these slurries when tested under the same conditions.

NACA RM L9K29

TANK INVESTIGATION OF THE GRUMMAN JRF-5 AIRPLANE FITTED WITH HYDRO-SKIS SUITABLE FOR OPERATION ON WATER, SNOW, AND ICE. Kenneth L. Wadlin and John A. Ramsen. June 12, 1950. 30p. diagrs., photos. (NACA RM L9K29)

Results are presented from tank tests of a 1/8-size powered dynamic model of the Grumman JRF-5 airplane fitted with tandem hydro-skis and auxiliary wing-tip skids suitable for operation on water, snow, and ice. Take-off stability and control of the airplane would be adequate for water operation with this arrangement. Water take-offs would be possible with the available thrust. Landing behavior in smooth water would be satisfactory with yaw up to 15°. Motions and accelerations during landings in rough seas would be much less than those for the airplane without skis. Accelerations in 7-foot waves would be less than those for the airplane without skis in 4-foot waves.

FLIGHT DETERMINATION OF DRAG AND PRESSURE RECOVERY OF A NOSE INLET OF PARABOLIC PROFILE AT MACH NUMBERS FROM 0.8 TO 1.7. Richard I. Sears and C. F. Merlet. October 1951. 22p. diagrs., photo. (NACA RM L51E02)

External-drag and total-pressure-recovery data are presented for a nose inlet of parabolic arc profile. The tests were made of rocket-propelled models in free flight at Mach numbers from 0.8 to 1.7. The Reynolds number based on the 10-inch body diameter varied from about 4×10^6 to 9×10^6.

NACA RM L51E21

TANK INVESTIGATION OF THE GRUMMAN JRF-5 AIRPLANE WITH A SINGLE HYDRO-SKI AND AN EXTENDED AFTERBODY. John A. Ramsen and George R. Gray. August 1951. 12p. diagrs., photos. (NACA RM L51E21)

Results from a tank investigation of a 1/8-size powered dynamic model of the Grumman JRF-5 airplane fitted with a single hydro-ski and an extended afterbody are presented. A comparison with results of a previous investigation with tandem hydro-skis indicates that the afterbody extension in place of the tail ski reduced the maximum resistance 10 percent. A further reduction of 3 percent was obtained by removal of the wing-tip skids. The effects on longitudinal stability were negligible.

NACA RM L52B28

FORCE CHARACTERISTICS IN THE SUBMERGED AND PLANING CONDITION OF A 1/5.78-SCALE MODEL OF A HYDRO-SKI-WHEEL COMBINATION FOR THE GRUMMAN JRF-5 AIRPLANE. Norman S. Land and Charles A. Pelz. July 1952. 28p. diagrs., tab. (NACA RM L52B28)

Force characteristics determined from tank tests of a 1/5.78-scale model of a hydro-ski-wheel combination for the Grumman JRF-5 airplane are presented. The model was tested in both the submerged and planing conditions over a range of trim, speed, and load sufficiently large to represent the most probable full-size conditions.

NACA RM L52F12

INVESTIGATION OF VANES IMMERSED IN THE JET OF A SOLID-FUEL ROCKET MOTOR. Leo V. Giladett and Andrew R. Wineman. September 1952. 30p. diagrs., photos., tab. (NACA RM L52F12)

The results of a series of static tests of a jet-vane configuration oscillated in the jet of the 6.25-inch Deacon solid-fuel rocket motor are presented. The lift, drag, hinge moment, and center of pressure were determined for deflection angles of ±12.5°. The effect of the jet vanes on the rocket-motor performance was determined, as well as the effect of the jet on both SAE 1020 steel and grade 15 carbon-graphite vane materials. The SAE 1020 steel vanes have been found satisfactory for inclusion into a jet-vane stabilization system.

NACA RM L52J23

AN INVESTIGATION OF THREE NACA 1-SERIES NOSE INLETS AT SUBSONIC AND TRANSONIC SPEEDS. Robert E. Pendley, Joseph R. Milillo, and Frank F. Fleming. January 1953. 71p. diagrs., photos., tab. (NACA RM L52J23)

Schlieren photographs and drag, surface-pressure, and pressure-recovery measurements are presented for three NACA 1-series nose inlets at zero angle of attack for a Mach number range extending from about 0.6 to 1.11. Pressure-recovery data for two of these inlets are presented at additional angles of attack of 4°, 7°, and 10°. The mass-flow-ratio range extended from about 0.2 up to the choking value. Small differences were found in the drag characteristics at subsonic speeds, but an appreciable effect of inlet proportion was indicated at supersonic speeds.

NACA RM L53F08a

A FLIGHT INVESTIGATION OF THE EFFECTS OF VARIED LATERAL DAMPING ON THE EFFECTIVENESS OF A FIGHTER AIRPLANE AS A GUN PLATFORM. Helmut A. Kuehnel, Arnold R. Beckhardt, and Robert A. Champine. August 1953. 30p. diagrs., photo., tabs. (NACA RM L53F08a)

An investigation has been made of the effects of varied lateral damping on the effectiveness of a jet-powered fighter aircraft as a gun platform. Flight

DECLASSIFIED NACA RESEARCH REPORTS

tests were conducted at three conditions of damping and two atmospheric turbulence levels with both a fixed-reticle and a gyro-computing gunsight. A brief investigation was also made with a fixed-reticle telescopic gunsight. Results of simulated strafing runs made in this investigation indicate that the gun-line dispersion could be expected to decrease about 7 percent by increased lateral damping and to increase about 85 percent by decreased damping and about 40 percent by rough air of the type encountered. Use of the telescopic sight indicated a 20-percent decrease in gun-line dispersion.

NACA RM L53F18

FREE-FLIGHT LONGITUDINAL-STABILITY INVESTIGATION INCLUDING SOME EFFECTS OF WING ELASTICITY FROM MACH NUMBERS OF 0.85 TO 1.34 OF A TAILLESS MISSILE CONFIGURATION HAVING A 45° SWEPTBACK WING OF ASPECT RATIO 5.5. Richard G. Arbic and Warren Gillespie, Jr. August 1953. 30p. diagrs., photos., tabs. (NACA RM L53F18)

A free-flight longitudinal-stability investigation was conducted between Mach numbers 0.85 and 1.34 to obtain the aerodynamic characteristics of a long-range ground-to-ground missile having a wing of aspect ratio 5.5, 45° sweepback, and taper ratio 0.4 mounted on a body with a vertical tail but with no horizontal tail. Two models were flown, one with a wing of steel and the other with a wing of 75S-T6 aluminum alloy permitting determination of aeroelastic effects on the lift-curve slope and aerodynamic center. Flight data were analyzed to obtain longitudinal stability, zero-lift drag, and longitudinal trim data.

NACA RM L53F18a

AN EXPERIMENTAL STUDY OF FIVE ANNULAR AIR INLET CONFIGURATIONS AT SUBSONIC AND TRANSONIC SPEEDS. Robert E. Pendley, Joseph R. Milillo, Frank F. Fleming, and Carroll R. Bryan. August 1953. 86p. diagrs., tabs. (NACA RM L53F18a)

Four annular inlets consisting of an NACA 1-80-100 nose inlet containing a short, rapidly diverging diffuser and fitted alternately with an elliptical, a parabolic, a 14°-conical, and a 22°-conical central body were tested through a Mach number range of 0.6 to 1.1 and a mass-flow range of about 0.12 to the choking value. Presented are drag, surface-pressure, and pressure-recovery measurements at an angle of attack of 0° and surface-pressure and pressure-recovery measurements at angles of attack of 4°, 7°, and 10°. In addition, the drag of an NACA 1-80-300 nose inlet fitted with the elliptical central body was tested and presented at a Mach number of 1.1. Reductions in external drag, obtained by utilizing the configurations with lower pressures over the central-body surface, were accompanied by resultant losses in pressure recovery.

NACA RM L53F19

SOME MEASUREMENTS OF AERODYNAMIC FORCES AND MOMENTS AT SUBSONIC SPEEDS ON A RECTANGULAR WING OF ASPECT RATIO 2 OSCILLATING ABOUT THE MIDCHORD. Edward Widmayer, Jr., Sherman A. Clevenson, and Sumner A. Leadbetter. August 1953. 45p. diagrs., tabs. (NACA RM L53F19)

Some measurements were made of the aerodynamic forces and moments acting on a rectangular wing of aspect ratio 2 which was oscillated about the midchord. Results are presented for a range of Mach number from 0.15 to 0.81, a range of reduced frequency from 0.15 to 1.32, and a range of Reynolds number from 0.60×10^6 to 9.21×10^6. A comparison of the measured aerodynamic forces and moments is made with some available published data. Comparisons are also made between the measured data and theoretical incompressible-flow coefficients obtained from the aspect-ratio theory of Reissner, the aspect-ratio theory of Lawrence and Gerber, and the two-dimensional-flow theory. Some experimental results pertaining to the influence of wind-tunnel-wall effects on nonsteady aerodynamic measurement are included.

NACA RM L54F04

THEORETICAL INVESTIGATION BASED ON EXPERIMENTAL FREQUENCY-RESPONSE MEASUREMENTS OF AN AUTOMATIC ALTITUDE CONTROL IN COMBINATION WITH A SUPERSONIC MISSILE CONFIGURATION. Ernest C. Seaberg, Edward S. Geller, and William W. Willoughby. August 1954. 28p. diagrs., photos. (NACA RM L54F04)

An investigation has been made to determine the possibility of maintaining flight of a ground-launched missile of the boost-glide type at a constant predetermined altitude with the view toward using the results obtained as a guide to future problems encountered in altitude stabilization of long-range, high-altitude vehicles. The results show that the control system can be made to function successfully for the low-altitude application and it is indicated that it will perform satisfactorily at high altitude.

NACA RM L54F08

PRESSURE DISTRIBUTIONS ON PLUG- AND SEMAPHORE-TYPE SPOILER AILERONS ON A 35° SWEPTBACK WING OF ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION AT HIGH SUBSONIC SPEEDS. Alexander D. Hammond and William C. Hayes, Jr. August 1954. 55p. diagrs., tabs. (NACA RM L54F08)

This paper presents the pressure distributions at several spanwise stations on a plug-type spoiler and at several stations on one segment of a semaphore-spoiler configuration. The spoilers were located along the 70-percent chord line of a semispan 35° sweptback wing which had an aspect ratio of 4, a taper ratio of 0.6, and NACA 65A006 airfoil sections parallel to free stream. The tests were made at angles of attack up to 20° at Mach numbers from 0.60 to 0.93 for several spoiler projections.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L54F22

INVESTIGATION OF THE EFFECT OF BALANCING TABS ON THE HINGE-MOMENT CHARACTERISTICS OF A TRAILING-EDGE FLAP-TYPE CONTROL ON A TRAPEZOIDAL WING AT A MACH NUMBER OF 1.61. Douglas R. Lord and Cornelius Driver. August 1954. 23p. diagrs., photo. (NACA RM L54F22)

An investigation has been made at a Mach number of 1.61 for a Reynolds number of 3.6×10^6 to determine the effect of 10-percent control-area attached tabs on the hinge-moment characteristics of a trailing-edge control on a trapezoidal wing having a 23° sweptback leading edge, aspect ratio of 3.1, and taper ratio of 0.4. Tests were made for tab deflections of approximately 0°, -10°, and -20° at angles of attack from -12° to 12° over the control-deflection range from -30° to 30°. The basic hinge-moment coefficients are presented as functions of control deflection and tab deflection. Experimental and theoretical analyses are made of the tab incremental hinge-moment coefficients due to tab deflection, control deflection, and angle of attack; analyses are also made of the ratio of tab to control deflection required for balanced control hinge moments with tabs located either inboard or outboard along the control trailing edge.

NACA RM L55F01a

ANALOG STUDY OF THE EFFECTS OF VARIOUS TYPES OF CONTROL FEEL ON THE DYNAMIC CHARACTERISTICS OF A PILOT-AIRPLANE COMBINATION. Charles W. Mathews. August 1955. 13p. diagrs. (NACA RM L55F01a)

Some sources of control feel for the longitudinal control system of an airplane are discussed as to their usefulness and limitations. In particular, feel forces obtained from pilot's control inputs (such as stick force obtained from stick centering springs) are compared with feel forces obtained from the airplane's response (such as stick forces obtained from bob weights).

NACA RM L55F06

EFFECTS OF LEADING-EDGE RADIUS ON THE LONGITUDINAL STABILITY OF TWO 45° SWEPTBACK WINGS AS INFLUENCED BY REYNOLDS NUMBERS UP TO 8.20×10^6 AND MACH NUMBERS UP TO 0.303. Gerald V. Foster and William C. Schneider. July 1955. 65p. diagrs. (NACA RM L55F06)

Force-test data showing the effects of changes in leading-edge radius, aspect ratio, Reynolds number, and Mach number are presented for an uncambered 45° sweptback wing. Data are presented for leading-edge radii of 0.89, 0.50, and 0.25 percent chord; aspect ratios of 3 and 5; Reynolds numbers up to 8.2×10^6; and Mach numbers up to 0.30.

NACA RM L55F20

HYDRODYNAMIC PRESSURE DISTRIBUTION OBTAINED WITH A STREAMLINE BODY EQUIPPED WITH CHINE STRIPS. Bernard Weinflash. September 1955. 29p. diagrs., photos., tabs. (NACA RM L55F20)

Hydrodynamic pressure distributions are given for a streamline body equipped with chine strips and moving on a water surface. Test conditions were selected to indicate maximum negative pressures as well as effects of speed, trim, wetted length, and removal of the chine strips on the general form of the hydrodynamic pressure distribution.

NACA RM L55F22

SOME DESIGN IMPLICATIONS OF THE EFFECTS OF AERODYNAMIC HEATING. Richard R. Heldenfels. July 1955. 26p. diagrs. (NACA RM L55F22)

The structural design problems created by aerodynamic heating appear to be numerous, complex, and very severe. Two of these problems, creep and thermal buckling, are examined to indicate their effect on the design of structures for high-speed aircraft; then consideration is given to the use of insulation as a means of alleviating the effects of aerodynamic heating. The results show that creep may not be a significant factor, but thermal buckling may have a substantial effect on the structural design. The use of insulation has merit under certain conditions but poses many new design problems. These results are based on limited data and may change as more information becomes available.

NACA RM L55F28

AN EXPERIMENTAL INVESTIGATION OF A FLAT RAM-JET ENGINE ON A HELICOPTER ROTOR. Robert D. Powell, Jr., and James P. Shivers. January 1956. 27p. diagrs., photo. (NACA RM L55F28)

The propulsive and aerodynamic characteristics of a flat ram-jet engine suitable for powering a helicopter rotor have been determined on the Langley helicopter test tower. The specific fuel consumption of the flat ram-jet engine with nonuniform fuel injection and radially elongated combustion chamber is not adversely affected by high centrifugal accelerations up to 500g. The flat engine has lift-drag ratios up to three times as great as those of the equivalent circular engine over the range of angle of attack covered.

NACA RM L55F29

DISTRIBUTION OF LOSSES BEHIND A COMPRESSOR ROTOR AS MEASURED BY A ROTATING RAKE. William R. Godwin. January 1956. 66p. diagrs., photo. (NACA RM L55F29)

A rotating total-pressure survey rake was employed to obtain wake measurements of a compressor rotor. The results are compared with two-dimensional cascade data of similar geometry in the

DECLASSIFIED NACA RESEARCH REPORTS

form of wake distributions, total-pressure-loss coefficients, momentum-loss coefficients, and turning angles covering the Mach number range from 0.2 to 0.8. Also presented are total-pressure-loss contour plots covering the span of one blade for the angle-of-attack and Mach number range. The results show there was considerable radial flow of the inboard-blade boundary layer and little radial flow of the inner casing boundary layer. Under conditions of low angle of attack, the mean-section losses were less than those of the cascade; these differences could not be attributed to "three-dimensional relieving." In general, the total-pressure-loss coefficients, momentum-loss coefficients, and turning angles for the rotor were in close agreement with those of the two-dimensional cascades.

NACA RM L55H05

LOW-SPEED STUDY OF THE EFFECT OF FREQUENCY ON THE STABILITY DERIVATIVES OF WINGS OSCILLATING IN YAW WITH PARTICULAR REFERENCE TO HIGH ANGLE-OF-ATTACK CONDITIONS. John P. Campbell, Joseph L. Johnson, Jr., and Donald E. Hewes. November 1955. 93p. diagrs., photos., tab. (NACA RM L55H05)

Free-to-damp and forced-oscillation tests were made with a 60° delta wing, a 45° swept wing, and an aspect-ratio-3 unswept wing to determine the effects of frequency on the stability derivatives of wings oscillating in yaw over an angle-of-attack range from 0° to 30°. The tests were made at low Reynolds numbers and covered a range of the reduced frequency parameter $\omega b/2V$ of 0.08 to 0.30 for the free-oscillation tests and 0.01 to 0.12 for the forced-oscillation tests.

NACA RM L55L14

PRELIMINARY MEASUREMENTS OF THE AERODYNAMIC YAWING DERIVATIVES OF A TRIANGULAR, A SWEPT, AND AN UNSWEPT WING PERFORMING PURE YAWING OSCILLATIONS, WITH A DESCRIPTION OF THE INSTRUMENTATION EMPLOYED. M. J. Queijo, Herman S. Fletcher, C. G. Marple, and F. M. Hughes. April 1956. 35p. diagrs., photos. (NACA RM L55L14)

A preliminary investigation has been made to determine the effect of motion periodicity on the aerodynamic derivatives due to yawing velocity and yawing acceleration for a 60° delta wing, a 45° sweptback wing, and an unswept wing. Results were obtained from steady-state yawing tests and from tests of the models performing pure yawing oscillations at a reduced frequency of 0.23. A description of the design and function of the instrumentation used in the investigation is included in the appendix.

NACA RM L56A19

EXPERIMENTAL DETERMINATION OF THE EFFECTS OF FREQUENCY AND AMPLITUDE ON THE LATERAL STABILITY DERIVATIVES FOR A DELTA, A SWEPT, AND AN UNSWEPT WING OSCILLATING IN YAW. Lewis R. Fisher. April 1956. 67p. diagrs., photos. (NACA RM L56A19)

Three wing models were oscillated in yaw about their vertical axes to determine the effects of systematic variations of frequency and amplitude of oscillation on the in-phase and out-of-phase combination lateral stability derivatives resulting from this motion. The tests were made at a Mach number of 0.13 and Reynolds numbers of 1.6×10^6, for the 60° delta wing, and 0.71×10^6 for the 45° swept wing and the unswept wing.

NACA RM L56E31

THEORETICAL DETERMINATION OF WATER LOADS ON PITCHING HULLS AND SHOCK-MOUNTED HYDRO-SKIS. Emanuel Schnitzer. October 1956. 65p. diagrs., tab. (NACA RM L56E31)

A dynamic-camber theory was developed for determining the loads and motions of seaplanes with high length-beam ratios, shock-mounted hydro-skis and other bodies impacting or planing on a water surface while undergoing pitching rotation. Partial verification of this theory is obtained through comparisons with classical two- and three-dimensional linearized airfoil theory for steady and unsteady submerged motion and with some low-aspect-ratio oscillating airfoil data. The effects of pitching rotation on longitudinal pressure distribution are shown. Several example solutions were made which indicated that rotational effects were more important for the narrow hull than for the pivoted shock-mounted hydro-ski. Load reductions were predicted for this hydro-ski mounting over the fixed-trim rigidly mounted hydro-ski.

NACA Rept. 1267

PLASTIC DEFORMATION OF ALUMINUM SINGLE CRYSTALS AT ELEVATED TEMPERATURES. R. D. Johnson, A. P. Young, and A. D. Schwope. Battelle Memorial Institute. 1956. ii, 31p. diagrs., photos., tabs. (NACA Rept. 1267. Supersedes TN 3351)

A study was made of plastic deformation of aluminum single crystals over a wide range of temperatures. Results are presented of constant-stress creep tests, constant-load-rate tests, and constant-load creep tests. The effect of crystal orientation on the operative slip system was determined. The effect of small amounts of prestraining was studied and two high-resolution X-ray techniques were used to detect and follow the strain. Light and electron microscopy were used to study the complex nature of slip bands and kink bands on specimens deformed at elevated temperatures.

NACA Rept. 1274

SECOND-ORDER SUBSONIC AIRFOIL THEORY INCLUDING EDGE EFFECTS. Milton D. Van Dyke. 1956. ii, 23p. diagrs., tabs. (NACA Rept. 1274. Supersedes TN 3390 and portions of TN 3343)

Several recent advances are combined into a unified second-order theory for airfoil sections in subsonic flow. The method includes correction of the thin-wing approximation near stagnation points. Solutions for various profiles are compared with results of experiment and other theories. A computing scheme is given for treating any profile numerically.

NACA RM E57E02

REACTION OF FLUORINE WITH CARBON AS A MEANS OF FLUORINE DISPOSAL. Harold W. Schmidt. July 1957. 17p. diagrs., tab. (NACA RM E57E02)

Experiments have illustrated the feasibility of disposing of gaseous fluorine by reaction with charcoal. Fluorine and fluorine-oxygen and fluorine-nitrogen mixtures containing as little as 6.5 percent fluorine ignited spontaneously when impinged onto a bed of charcoal and reacted to produce chemically inert gaseous fluorocarbons. Fluorine and fluorine-oxygen mixtures were consumed at rates near 25 pounds per hour in an experimental portable reactor containing 6 cubic feet of charcoal; quantitative measurements of residual fluorine in the exhaust products ranged from 20.1 to 77.5 parts per million.

NACA TM 1409

REFLECTION AND REFRACTION OF ACOUSTIC WAVES BY A SHOCK WAVE. (Réflexion et refraction d'ondes acoustiques par une onde de choc.) J. Brillouin. July 1957. 42p. diagrs. (NACA TM 1409. Translation from Acustica, v.5, no.3, 1955, p.149-163)

This paper treats the problem of reflection and refraction of sound waves by a plane, uniform shock wave separating two regions, in both of which the fluid pressure and temperature are originally in equilibrium. Calculations are made of conditions that prevail in the two regions after the equilibrium in either one or the other region has been upset by incidence of a plane, uniform acoustic wave. Dynamic relationships show that the amplitude of reflected waves is always less than that of the incident wave, but the amplitude of refracted waves may, in certain cases, be greater than that of the incident wave.

NACA TN 3991

INTERFACE THERMAL CONDUCTANCE OF TWENTY-SEVEN RIVETED AIRCRAFT JOINTS. Martin E. Barzelay and George F. Holloway, Syracuse University. July 1957. 23p. diagrs., tabs. (NACA TN 3991)

Twenty-seven structural joint specimens of 2024-T3 and 2024-T4 aluminum alloy consisting of a T-stringer rivited to a 10- by 10-inch skin surface were tested under simulated aerodynamic heating with no external loading applied. Interface thermal conductance was determined from local transient-temperature records. The heat input (approximately 10,000 to 75,000 Btu/(sq ft)(hr)) was held constant during any given test and the duration of heating was from 15 to 50 seconds.

NACA TN 4007

AN INVESTIGATION OF DISCHARGE AND THRUST CHARACTERISTICS OF FLAPPED OUTLETS FOR STREAM MACH NUMBERS FROM 0.40 TO 1.30. Allen R. Vick. July 1957. 47p. diagrs. (NACA TN 4007)

Discharge and force characteristics of flapped outlets, rectangular in cross section, have been determined for stream Mach numbers from 0.40 to 1.30. The basic outlet configuration was unchanged, and different flaps were attached to the outlet. Results are presented in the form of design charts for such variables as outlet discharge-flow ratio, flap angle, flap hinge-point location, and flap aspect ratio. Also presented are the variations of outlet duct pressure at a zero discharge rate for different flap angles and aspect ratios.

NACA TN 4014

RECENT RESEARCH ON THE CREEP OF AIRFRAME COMPONENTS. Eldon E. Mathauser, Avraham Berkovits, and Bland A. Stein. July 1957. 12p. diagrs. (NACA TN 4014)

The results of recent research of the National Advisory Committee for Aeronautics on the creep of airframe components at elevated temperatures are summarized. Experimental lifetime data from plates and unstiffened circular cylinders are compared with predictions obtained from isochronous stress-strain curves. An analysis defining the magnitude of creep strains that produce significant structural deformations is presented. A comparison of structural weight determined from assumed strength and creep criteria is made to establish temperature ranges in which creep is expected to influence structural design for various materials.

NACA TN 4019

SOME OBSERVATIONS ON STRESS-CORROSION CRACKING OF SINGLE CRYSTALS OF AZ61X MAGNESIUM ALLOY. F. Meller and M. Metzger, Columbia University. July 1957. 23p. diagr., photos., tabs. (NACA TN 4019)

Exploratory tests were made of the stress-corrosion cracking of single crystals of solution-treated AZ61X magnesium alloy in distilled water, in 0.5 and 1 percent hydrofluoric acid, and in a salt-chromate solution consisting of 35 grams of sodium chloride to 20 grams of potassium chromate per liter. The path chosen by the crack is attributed to mechanical rather than electrochemical factors and the possible importance of prior deformation is pointed out.

NACA TN 4026

EFFECTS OF THERMAL RELAXATION AND SPECIFIC-HEAT CHANGES ON MEASUREMENTS WITH A PNEUMATIC-PROBE PYROMETER. P. W. Kuhns. July 1957. (ii), 67p. diagrs., tabs. (NACA TN 4026)

Equations are derived which evaluate the effects of thermal vibrational relaxation and specific-heat changes on pneumatic-probe pyrometer measurements in the region 1000° to 3000° K and $0.3 < \text{Mach number} < 2.0$. Examples are given for typical probes in two combustion mixtures.

NACA TN 4028

PRELIMINARY INVESTIGATION OF PROPANE COMBUSTION IN A 3-INCH-DIAMETER DUCT AT INLET-AIR TEMPERATURES OF 1400° TO 1600° F. Erwin A. Lezberg. July 1957. 19p. diagrs., photos., tab. (NACA TN 4028)

Ignition delays and combustion efficiencies were determined for propane injected into a heated airstream. Delays of 7 to 49 milliseconds occurred over the range of temperatures investigated; these results followed the Arrhenius relation with an apparent activation energy of 43 kilocalories per mole. Flames stabilized at the fuel injector burned to high efficiencies in lengths of 6 inches or more and were insensitive to changes in air temperature, pressure, or fuel-air ratio. Flames stabilized downstream of the injector by spontaneous ignition burned only to 70- to 80-percent completion at a length of 18 inches. These efficiencies were strongly dependent on temperature and burner length.

NACA TN 4033

SCREEN-TYPE NOISE REDUCTION DEVICES FOR GROUND RUNNING OF TURBOJET ENGINES. Willard D. Coles and Warren J. North. July 1957. 23p. diagrs., photos. (NACA TN 4033)

The noise suppression characteristics of several screen-type noise suppressors for ground running of jet engines have been studied. The addition of a cylindrical muffler to the jet screen eliminated the previously obtained (NACA TN 3452) increases in the sound radiated forward of the engine. The maximum sound pressure levels at 200 ft from the engine were reduced to 104 db (a 16-db reduction), and the overall sound power level was reduced 12 db. Air-jet tests showed that negligible additional improvement could be obtained by using multiple screens. Air-jet and engine tests showed airfoil-vane jet diffusers to be less effective than screens.

CURRENT NACA RESEARCH REPORTS

NACA TN 4050

STUDIES OF STRUCTURAL FAILURE DUE TO ACOUSTIC LOADING. Robert W. Hess, Robert W. Fralich, and Harvey H. Hubbard. July 1957. 11p. diagrs., tab. (NACA TN 4050)

Some discussion of the acoustic fatigue problem of aircraft structures is given along with data pertaining to the acoustic inputs from some powerplants in common use. Comparisons are given for results of some fatigue tests of flat panels and cantilever beams exposed to both random and discrete-type inputs. In this regard it appears that both the stress level of the test and the type of model are significant; hence, no generalization can be made at this time. With regard to increasing the fatigue life, it was noted that increased stiffening of a panel due to curvature and pressure differential is particularly beneficial.

NACA TN 4055

EFFECTS OF AIRPLANE FLEXIBILITY ON WING BENDING STRAINS IN ROUGH AIR. Thomas L. Coleman, Harry Press, and C. C. Shufflebarger. July 1957. 22p. diagrs. (NACA TN 4055)

Some results on the effects of wing flexibility on wing bending strains as determined from flight tests of a Boeing B-29 and a Boeing B-47A airplane in rough air are presented. Results from an analytical study of the flexibility effects on the B-29 wing strains are compared with the experimental results. Both the experimental and calculated results are presented as frequency-response functions of the bending strains at various spanwise wing stations to gust disturbances. In addition, some indirect evidence of the effect of spanwise variations in turbulence on the responses of the B-47A airplane is presented.

NACA TN 4058

CALCULATED EFFECT OF SOME AIRPLANE HANDLING TECHNIQUES ON THE GROUND-RUN DISTANCE IN LANDING ON SLIPPERY RUNWAYS. John A. Zalovcik. July 1957. 30p. diagrs., tabs. (NACA TN 4058)

Some calculations were made on the basis of simplifying assumptions to determine the effect of maintaining a nose-high attitude angle on the ground-run distance for several types of jet airplanes landing on slippery runways. The airplanes considered were a swept-wing transport and unswept-, swept-, and delta-wing fighters. Some computations were also made to indicate the effect of instantaneous flap retraction on the ground-run distance.

NACA TN 4059

NOISE SURVEY OF A FULL-SCALE SUPERSONIC TURBINE-DRIVEN PROPELLER UNDER STATIC CONDITIONS. Max C. Kurbjun. July 1957. 20p. diagrs., photo., tab. (NACA TN 4059)

Overall sound-pressure levels and frequency spectra of the noise emitted from a 7.2-foot-diameter, 3,500-rpm, three-blade supersonic propeller mounted on a turbine-powered vehicle have been obtained under static conditions about the propeller at a 100-foot radius. The results are compared with the results of a turbine-driven airplane of conventional design. The effects of power and rotational-speed changes on the noise levels and spectra are also determined.

NACA TN 4061

FLIGHT MEASUREMENTS OF BOUNDARY-LAYER TEMPERATURE PROFILES ON A BODY OF REVOLUTION (NACA RM-10) AT MACH NUMBERS FROM 1.2 TO 3.5. Andrew G. Swanson, James J. Buglia, and Leo T. Chauvin. July 1957. 40p. diagrs., photos. (NACA TN 4061)

A parabolic body of revolution, the NACA RM-10, was flight tested at Mach numbers up to 3.5 and Reynolds numbers up to 140×10^6 (based on length to the rake and probe measuring station). Boundary-layer temperature profiles determined from total-temperature probes showed excellent agreement with profiles predicted from the theory of Crocco. Skin-friction coefficients determined by the momentum method from total-pressure-rake data were in fair agreement with the Van Driest theory for flat plates with compressible turbulent boundary layers. Heat-transfer measurements indicated a transition Reynolds number (laminar to turbulent flow) of about 15×10^6.

NACA TN 4062

EFFECT OF SWEEP ON PERFORMANCE OF COMPRESSOR BLADE SECTIONS AS INDICATED BY SWEPT-BLADE ROTOR, UNSWEPT-BLADE ROTOR, AND CASCADE TESTS. William R. Godwin. July 1957. 43p. diagrs. (NACA TN 4062)

In order to determine the induced effect of sweep on an axial-flow compressor blade, a 30° swept version of an unswept-blade rotor (described in NACA TN 3806) having NACA 65-series blade sections and a 0.69 hub-tip ratio was tested up to a Mach number of 0.45. The comparisons, at three sections, of pressure distributions for the swept and unswept blades indicated that, in order to obtain the same effective angles of attack, the swept blade required an additional twist of 3.8° for the entire radial span. Two-dimensional cascade data adequately predicted the turning angle through the swept-blade rotor if the change in axial velocity provided by the blockage of the trailing portion of the blade was taken into account.

BRITISH REPORTS

N-36628*

Aeronautical Research Council (Gt. Brit.)
MEASUREMENTS OF THE TURBULENT SURFACE-FRICTION DRAG OF A FLAT PLATE IN TWO-DIMENSIONAL FLOW. R. C. Pankhurst, E. F. Relf, and W. S. Walker. August 31, 1954. 6p. diagrs., tab. ARC 17,024; FM 2120.
(Ask for N-36628*)

The surface-friction drag of a two-dimensional flat plate with turbulent boundary layers has been measured by the wake-traverse method in the 13-foot by 9-foot wind tunnel at the N.P.L. over the range of Reynolds number from 4×10^6 to 13×10^6. The results are all close to, and are mostly intermediate between, the Schoenherr and the Prandtl-Schlichting values.

THE EFFECT ON WEATHER MINIMA OF APPROACH SPEED, COCKPIT CUT-OFF ANGLE AND TYPE OF APPROACH COUPLER FOR A GIVEN LANDING SUCCESS RATE AND LEVEL OF SAFETY. E. S. Calvert and J. W. Sparke. January 1957. 22p. diagrs. RAE Tech. Note EL. 130.
(Ask for N-48652*)

This note attempts to make a realistic assessment of the performance of various approach couplers using the results of some tests made during the past two years, both full-scale and on a landing simulator. The influence of cockpit cutoff angle, approach speed, ground lighting pattern, and runway width on the weather which can be defeated by a coupler of given accuracy is discussed. One important result of the simulator tests is that in marginal weather visual guidance in the vertical plane may be defective at heights above 100 feet. The implications of this on the cockpit and G.C.A. procedures are pointed out, and some suggestions are made for improving safety.

ON A TYPE OF AIR LUBRICATED JOURNAL BEARING. G. L. Shires. 1957. 44p. diagrs. ARC CP 318. (Ask for N-48747*)

Experimental journal bearings have been constructed which will support a radial load when supplied with air at high pressure. The principles of this type of bearing are discussed, and some of the available experimental data analyzed. The results are collated in terms of a nondimensional parameter based on the theory of viscid flow between two adjacent surfaces and these means are extrapolated to give performance figures for bearings outside the range of the experiments. The estimated performance is then compared with that of conventional bearings, and conclusions are drawn regarding possible applications of this type of air lubrication.

IMPACT MEASUREMENTS ON A LARGE MODEL OF A REPRESENTATIVE LANDPLANE FUSELAGE ON WATER. J. E. Allen. 1956. 69p. diagrs., photos., tabs. ARC CP 283. (Ask for N-48748*)

An experimental investigation has been made into splash-up, impact pressures, and impact forces occurring during controlled alightings on smooth water of a representative landplane fuselage of elliptical cross section. The width of the actual wetted surface of the cylinder was found to be $\sqrt{2}$ times the width which would be wetted for immersion to the same draft without splash-up. Pressure distributions are presented in the form of data for several landings over a range of initial attitudes and at flight-path angles down to 1.5°. The acceleration results are of limited usefulness due to imperfections in the apparatus. Photographs are included of the external spray formation. Results are not generally applicable to design cases for ditching until a rational theory of impact of fuselage shapes be made available.

ILL-CONDITIONED FLUTTER EQUATIONS AND THEIR IMPROVEMENT FOR SIMULATOR USE. E. G. Broadbent. 1956. 22p. diagrs., tab. ARC CP 298. (Ask for N-48749*)

If simple arbitrary modes of the form η^a are used as coordinates in a wing-flutter calculation, the equations are ill conditioned and cannot be solved satisfactorily on a simulator. This ill conditioning can be avoided by transforming the flutter matrix so as to reduce the inertia couplings between like modes to zero. This transformation is described with numerical examples, and some observations are made on the general problems of choice of coordinates in a flutter calculation.

LOW SPEED WIND TUNNEL TESTS ON PERFORATED SQUARE FLAT PLATES NORMAL TO THE AIRSTREAM: DRAG AND VELOCITY FLUCTUATION MEASUREMENTS. B. G. de Bray. 1957. 13p. diagrs., tab. ARC CP 323. (Ask for N-48751*)

The effects of perforations upon the drag, and velocity fluctuations downstream, of square plates normal to the airstream are described. It is shown that perforations can have a powerful effect upon the level of velocity fluctuations, particularly the low-frequency components, with only a comparatively small reduction in drag coefficient. It is also shown that perforating the central region only of a square plate is as effective in reducing velocity fluctuations as perforating the whole plate while giving a slightly higher drag coefficient than the latter. On the other hand, perforations near the periphery only are less effective.

A FLIGHT INVESTIGATION OF THE WAKE BEHIND A METEOR AIRCRAFT, WITH SOME THEORETICAL ANALYSIS. D. R. Andrews. 1956. 34p. diagrs., photos., tab. ARC CP 282. (Ask for N-48753*)

An experimental investigation of the wake behind a Meteor 4 aircraft has been carried out, and theory used wherever possible to confirm and extend the results obtained. Measurements show that for the condition covered in these tests, the jet velocity has fallen to a negligible value by about 200 to 300 ft behind the jet exit. The jet would be expected to persist longest under take-off conditions although no measurements were made of this specific case. The major disturbances behind an aircraft are due to the trailing vortices and these decay only slowly. Tests with a Vampire flying in the wake of the Meteor show that the strength of these vortices has only fallen to about half its initial value by 8000 ft behind the aircraft.

FATIGUE LOADINGS IN FLIGHT LOADS IN THE FUSELAGE AND NOSE UNDERCARRIAGE OF A VARSITY. E. W. Wells. 1956. 19p. diagrs., tabs. ARC CP 287 (Ask for N-48755*)

Flight tests have been made on a Varsity to obtain data on the fatigue loads in the fuselage and the nose undercarriage. The data are tabulated in terms of the number of load ranges of a given magnitude occurring during various ground and flight conditions. An estimate is made of the loads in a typical operational training flight to show the relative importance of the various conditions. A relationship is established between the fuselage loads and the accelerations at the aircraft c.g. when flying in turbulence; this enables the results from the flight tests to be linked to operational data obtained on gusts.

FIN-AND-RUDDER LOADS IN A YAWING MANOEUVRE: EFFECT OF DIRECT AND POWER ASSISTED RUDDER MOVEMENT. D. R. Puttock. 1956. 51p. diagrs., tab., charts. ARC CP 301. (Ask for N-48757*)

The severity of a yawing maneuver specified for design purposes is investigated. The maneuver does not always represent the most critical case, higher fin-and-rudder loadings being obtainable when the specified frequency of rudder movement is changed. The inclusion of a power unit in the circuit may impose restrictions on the rudder movement, leading to a reduction in the severity of the loading. Analytical treatment includes the derivation of exact expressions for the angle of sideslip, fin-and-rudder load, and rudder hinge moment induced by a sinusoidal rudder movement of arbitrary frequency. These expressions are analyzed to determine how the maxima of each of the quantities are affected by variations in the frequency of the rudder movement. Computational charts are included. The problems are illustrated with a numerical example.

COMPRESSOR CASCADE FLUTTER TESTS. PART II. 40° CAMBER BLADES, LOW AND MEDIUM STAGGER CASCADES. D. A. Kilpatrick and J. Ritchie. 1956. 19p. diagrs., photos. ARC CP 296. (Ask for N-48758*)

The tests reported here continue the cascade flutter investigation at N.G.T.E., the first part of which, already reported, deals with 20° camber blades, medium, and high stagger cascades. In agreement with those test results, three main flutter zones of high stress are detected, namely, stalling flutter, shock-stalling flutter, and choking flutter. Their disposition, with reference to the aerodynamic cascade characteristics, is also in general agreement. Good correlation of stalling flutter with the experimentally determined blade-force derivative with respect to incidence, is obtained, but only incomplete correlation of shock-stalling and choking flutter with the blade-force derivative with respect to Mach number.

TESTS ON ROUGH SURFACED COMPRESSOR BLADING. R. C. Turner and Hazel P. Hughes. 1956. 37p. diagrs., photos. ARC CP 306. (Ask for N-48759*)

Six stages of medium stagger-free vortex blading, with rough surface finish, were tested in the N.G.T.E. 106 compressor. Overall characteristics were determined at various speeds and compared with those of similar blading with the conventional smooth finish. It was established that appreciable losses in temperature-rise coefficient and efficiency were exhibited, and hoped-for gains in performance at low Reynolds numbers were not realized. There was no change in the general shape of the characteristics at any speed. The condition of the boundary layer on a blade of the fifth-stage stator row was investigated by means of pitot traverse and sensitive film techniques. No appreciable difference was found in this respect between the two sets of blades.

LOW SPEED STATIC AND FLUCTUATING PRESSURE DISTRIBUTIONS ON A CYLINDRICAL BODY WITH A SQUARE FLAT PLATE AIRBRAKE. T. B. Owen. 1956. 18p. diagrs., tab. ARC CP 288. (Ask for N-48761*)

There is a very rapid increase both in the root-mean-square amplitude of the pressure fluctuations and in the area of the body affected, if the brake angle is increased beyond 50°. At the lower frequencies there is a large increase in amplitude between 40° and 50° which is associated with the appearance of a regular shedding of turbulent eddies. On the model used, with an average gap of about 27 percent of the length of the side of the brake, the shedding frequencies are in close agreement with those measured on an isolated plate at the smaller brake angles and slightly higher than on an isolated plate at the higher brake angles. The fluctuating pressures due to the brake are little affected by the distance of the brake from the tail of the body.

A GRAPHICAL METHOD OF PREDICTING THE OFF DESIGN PERFORMANCE OF A COMPRESSOR STAGE. J. F. Louis and J. H. Horlock. 1957. 21p. diagrs. ARC CP 320. (Ask for N-48764*)

It has been seen in a previous paper that analytical solutions of compressor stage performance based on actuator disk theory are extremely difficult, and reliable only when the outlet angle distributions from the blade rows are the same at all flow rates. No analytical method is able to describe the flow when the stall is reached. In order to overcome these difficulties a graphical method is developed for predicting stage off-design performance even when the stall occurs. The method is first used to predict the performance of a stage of "constant α_3" design, and experiments confirm the prediction. Next, the method is used as a basis for comparison of different designs of a free-vortex stage.

PROBLEMS IN COMPUTATION OF AERODYNAMIC LOADING ON OSCILLATING LIFTING SURFACES. H. C. Garner and A. E. A. Acum. 1957. 15p. ARC CP 309. (Ask for N-48766*)

The linearized theories of oscillating wings in subsonic and supersonic flow are formally discussed. The computability of the subsonic problem is considered when Mach number, frequency, and aspect ratio are arbitrary and also when any one of these parameters takes extreme values. Methods of treating aerodynamic flutter problems are briefly outlined. The most general subsonic problem for a rectangular wing, already solved numerically on a desk machine, should now be examined with a view to mechanized computation. Special theories, particularly suited to high-speed computation, should, if possible, be extended to arbitrary frequency and Mach number.

ACTUATOR DISC THEORIES APPLIED TO THE DESIGN OF AXIAL COMPRESSORS. A. C. Carmichael and J. H. Horlock. 1957. 18p. diagrs., tab. ARC CP 315. (Ask for N-48767*)

A relatively simple method is given for finding the flow conditions in the proximity of blade rows when the variation in whirl or tangential velocity is known. The radial variations in axial velocity that would be attained in radial equilibrium are first estimated using the radial equilibrium equations and then modified to allow for the interference effect of the adjacent blade rows on the axial velocity distribution between the blade rows. The second part of the paper gives some solutions to the radial equilibrium equations for a useful general variation in whirl velocity. This variation gives constant radial work rotors and includes the free vortex and constant reaction designs as particular solutions. The combination of these results gives a design method which should be useful in the design of axial compressors.

BOUNDARY LAYER SEPARATION IN TWO-DIMENSIONAL SUPERSONIC FLOW. G. E. Gadd and D. W. Holder. 1956. 16p. diagrs. ARC CP 270. (Ask for N-48769*)

Whenever boundary-layer separation occurs in two-dimensional supersonic flow there is a fairly sharp increase of pressure before separation. It is found that the ratio of the pressure at the separation point S to the pressure at the position 0 just upstream of the sharp pressure rise, usually depends primarily on the external-flow Mach number and state of the boundary layer at 0, and is not greatly affected by the nature of the particular agency provoking separation. This is in marked contrast to the state of affairs in subsonic flow, and in fact in this respect conditions in supersonic flow are much simpler than those at low speeds.

Aeronautical Research Council (Gt. Brit.)
SOME ASPECTS OF COMPRESSOR STAGE DESIGN. J. F. Louis and J. H. Horlock. 1957. 18p. diagrs. ARC CP 319. (Ask for N-48770*)

The first section deals with the direct problem of the performance of given compressor stages and indicates how the blade sections of various designs approach the stall point. In the second part, a method is presented which combines the solutions of the indirect and direct problems. This method enables a designer to determine stages which will satisfy the imposed design conditions and to predict their off-design performance up to the stalling point. These stages differ in the distribution of pressure rise between rotor and stator. This choice of reaction is investigated in the off-design performance and may enable the designer to choose the optimum blading. In both sections actuator disk theory is used in the derivation of the equations of the flow.

Aeronautical Research Council (Gt. Brit.)
ON THE STABILITY OF A LAMINAR WAKE. C. H. McKoen. (Abridged version of author's thesis at the Univ. of London). 1956. 20p. diagr., tab. ARC CP 303. (Ask for N-48776*)

A perturbation method of solving the problem of stability in an unlimited field of flow is developed and used to investigate the stability of the laminar wake formed by a flat plate. The inviscid problem of the wake formed by a flat plate is investigated, and the eigen-value of α for the neutral disturbance is found to be $\alpha_s = 4.0$. A detailed account is given of the perturbation method which is developed. The necessary and sufficient condition that an integral of the small disturbance equation should satisfy the boundary conditions for the wake is established. This condition is found to lead to a simple determination of the (α, R) curve, and this curve is found for the neutral disturbances. The method fails to predict a minimum critical Reynolds number, only because the approximations made in the above conditions are only valid for large Reynolds numbers.

LARGE SCALE FATIGUE TESTS ON COMPLETE SECTIONS OF ALUMINUM AND MAGNESIUM ALLOYS. (1957). 28p. diagrs., photos., tabs. MOS S & T Memo. 2/57. (Ask for N-48800*)

It has been shown by tests on three aluminum alloys and one magnesium-base alloy that conventional methods of fatigue testing using small machined and polished cylindrical specimens or coupons can give results which in no way indicate the fatigue strength of the unmachined sections from which the specimens were cut. The testing techniques employed, that is, rotating cantilever and reversed bending, do not in themselves appear to have contributed markedly to the observed differences in fatigue strength, but there is evidence to support the view that a rectangular-shaped section gives a slightly lower fatigue strength than a round specimen.

PREDICTION OF TRANSITION IN THE BOUNDARY LAYER ON AN AEROFOIL. L. F. Crabtree. January 1957. 10p. diagrs. RAE Tech. Note Aero 2491. (Ask for N-48802*)

Transition to turbulence in the boundary layer on an airfoil may occur in several different ways, not the least important of which is by bubble separation of the laminar layer. Thus, in establishing an empirical criterion for the limit of existence of a laminar boundary layer the necessary parameters must be able to describe separation and instability, as well as being physically reasonable and simple to calculate and use. It is shown that only two parameters are necessary to fulfill these conditions, and that a universal curve may be constructed of boundary-layer Reynolds number R_{δ_2} against pressure gradient parameter m at transition. This curve may be used to predict transition, and an assessment of its accuracy in comparison with previous methods is given. Theoretically, the method can be extended to the limited case of bodies of revolution at zero incidence.

SOME LIMITING OXYGEN CONCENTRATIONS FOR DIFFUSION FLAMES IN AIR DILUTED WITH NITROGEN. R. F. Simmons and H. G. Wolfhard. February 1957. 12p. diagrs., tabs. RAE Tech. Note RPD 151. (Ask for N-48807*)

Fuels have been burned at the surface of a porous hemispherical burner of stainless steel, and the nitrogen concentration required to extinguish the flame has been determined. Results are given for a number of fuels in terms of the limiting oxygen index $\left[O_2/(O_2 + N_2)\right]$, and it has been found that these values are close to those obtained for premixed flames. Flame temperatures for these limit mixtures have been calculated, and it is suggested that a given mixture will only burn if its flame temperature exceeds the limiting flame temperature for that fuel.

A "WHIRLING ARM" TEST RIG FOR THE ASSESSMENT OF THE RAIN EROSION OF MATERIALS. A. A. Fyall and R. N. C. Strain. December 1956. 33p. diagrs., photos., tabs. RAE Chem. 509. (Ask for N-48808*)

This report deals with the development of the R.A.E. "whirling arm" test rig for assessing the rain erosion characteristics of materials in the speed range 250-500 mph. Details are given of the arm and of the test pieces. Natural rainfall and its simulation is discussed with special reference to the best drop size parameter. A detailed survey is made of a "spinning disk" technique of producing artificial rainfall under controlled conditions of drop size, concentration, and coverage of the test area. Results obtained on a range of typical aircraft materials, including examples from structural, radar, and vision applications are portrayed photographically. Future trends in simulated rain erosion test methods are indicated and discussed.

ATMOSPHERIC TURBULENCE ENCOUNTERED BY HERMES AIRCRAFT. J. R. Heath-Smith. January 1957. 20p. diagrs., tabs. RAE Tech. Note Structures 214. (Ask for N-48809*)

Acceleration records were obtained of the turbulence encountered by B.O.A.C. Hermes aircraft in 417,000 miles of operational flying on routes from London to East and West Africa. It is shown that turbulence decreases with increasing altitude. A result of the pilot's discretion in choice of altitude and course is that the gust frequency encountered during most of the cruise is about one-third of the average atmospheric gust frequency. Between 9,500 feet and 14,500 feet gusts were encountered four times as frequently over East and West African sectors as over European sectors.

AN ELECTRICAL ANALOGUE EQUIPMENT FOR GENERATING FUNCTIONS OF TWO VARIABLES. J. J. Gait and R. J. Garvey. January 1957. 59p. diagrs., photos., tab. RAE Tech. Note GW 449. (Ask for N-48810*)

A general need exists in the field of electronic analog computers and simulators for equipment capable of registering and providing an analog of functions of two variables. It is proposed in this note that single-valued functions of two independent variables, X and Y, be derived by suitably energizing an array of electrodes embedded in a flat resistive sheet. A probe, driven to any point (XY) on the sheet by a conventional plotting table, would then yield a voltage proportional to the function of X and Y. This proposition is examined, both theoretically and with a small-scale model, and it is concluded that the method is practicable. The design of a full-scale prototype unit is discussed.

A REPORT ON THE EFFECT OF GLASS SLIP COATS WHEN EMPLOYED AS DIE LUBRICANTS AND OXIDE BARRIERS IN FORGING. April 1957. 24p. tabs. MOS S & T Memo. 7/57. (Ask for N-48814*)

The object of this investigation was to determine whether glass and ceramic coatings applied to ferrous materials for the purpose of preventing the formation of oxide scale would, after heating, form a sufficiently viscous film to act as a lubricant between the die and the forging stock. The conclusion reached is that the metalized coatings which can be deposited as a spray, plate, or dip are more suitable for forging operations. It is, however, practicable with glass frits to provide a disposable barrier against the formation of oxide scale.

LONGITUDINAL STABILITY AND CONTROL OF THE SINGLE-ROTOR HELICOPTER. A. R. S. Bramwell. January 1957. 88p. diagrs., tab. RAE Rept. Naval 1. (Ask for N-48819*)

The equations of motion of the helicopter are presented and reduced to nondimensional form. The force and moment derivatives for the single-rotor helicopter (including tail plane if required) are given as simple formulas or in the form of charts. Comparisons are made with wind-tunnel and flight tests where possible. In the development of the theory, static and maneuver stabilities are introduced in a manner analogous to fixed-wing aircraft practice. It is shown that the static stability of the helicopter is proportional to the coefficient E in the stability quartic while the maneuvering qualities are represented by coefficient C. The NACA "divergence requirement" is expressed in terms of the "short-period" motion. Calculations show that the fitting of even a small tail plane provides a great improvement in stability and control.

A TECHNIQUE FOR IMPROVING THE PREDICTIONS OF LINEARISED THEORY ON THE DRAG OF STRAIGHT-EDGED WINGS. D. G. Randall. January 1957. 41p. diagrs. RAE Tech. Note Aero 2474. (Ask for N-48820*)

The curve of drag against Mach number for straight-edged wings, calculated by using the linearized theory of supersonic flow, displays discontinuities in slope at the various Mach numbers for which the edges are sonic. These features, which are not observed in practice, are due to the fact that linearized theory predicts an infinite pressure along a subsonic or sonic edge. It is shown that if the linearized equation of supersonic flow is used to determine the flow over straight-edged wings, but the linearized boundary condition is replaced by the full (nonlinear) boundary condition, these infinities disappear and are replaced by plausible values. On this basis a simple method is derived for improving the linearized predictions of the drag of straight-edged wings which exhibits satisfactory agreement with experimental results. While the technique is not directly applicable to ridge lines, an artifice renders them amenable to similar treatment.

Royal Aircraft Establishment (Gt. Brit.)
THE EFFECT OF PRELOADING UNDER VARIOUS ENVIRONMENTAL CONDITIONS ON THE STRENGTH OF GLASS-FIBRE LAMINATED PLASTICS. M. M. Cornford and W. W. Wright. November 1956. 35p. diagrs., tabs. RAE Tech.Note Chem.1291. (Ask for N-48822*)

The flexural strength of glass-fiber laminated plastics was determined after preloading under conditions of elevated temperature, high humidity, or both. The strength depended on the types of resin and glass cloth, and on the treatment applied to the glass cloth. An epoxy resin was superior to the other resins tested. High alkali glass-cloth polyester laminates were less affected than were similar low alkali glass-cloth laminates, but the latter possessed greater flexural strength. The use of vinyl trichlorosilane treated cloth resulted in improved strength figures with polyester, epoxy, and phenolic resins as compared with other treated cloths. It is recommended that when low alkali glass-cloth polyester laminates may be subjected to elevated temperature and humidity they should not be stressed beyond one-sixth of their ultimate strength. A combination of an epoxy resin with a low alkali glass cloth treated with vinyl trichlorosilane gave laminates having properties markedly superior to those of the other resin glass-cloth combinations tested.

THE STRUCTURE OF CHLORINE FLAMES. R. F. Simmons and H. G. Wolfhard. January 1957. 21p. diagrs., photos. RAE Tech.Note RPD 150. (Ask for N-48825*)

The structure and spectral emission of hydrocarbon-chlorine flames have been examined. The most striking feature of these flames is the large amount of carbon formed in the flame, and the radiation from these carbon particles has been used to measure the temperature profile through the flame front. This temperature was found to be considerably lower than the calculated adiabatic flame temperature and it is suggested that this is due to heat losses through radiation. The influence of chlorine on the limits of inflammability and spectral emission of air flames has been noted, and it has been found that, except for carbon monoxide flames, chlorine, unlike bromine, does not act as an inhibitor.

A SHOCK-EXPANSION THEORY APPLICABLE TO WINGS WITH ATTACHED SHOCK WAVES. L. M. Sheppard and K. D. Thomson. January 1957. 17p. diagrs. RAE Tech.Note Aero 2493. (Ask for N-48827*)

An extended shock-expansion theory applicable to three-dimensional wings with attached leading- and trailing-edge shock waves is presented in this note. Although the extended method has been derived for high Mach numbers only, preliminary comparisons of its predictions with those of linearized theory and the one experiment available indicate that it can be applied at quite low Mach numbers. The essential requirement found is that the wing edges must be "highly supersonic," that is, the component of free-stream velocity normal to the edges must not be in the low supersonic range. Tip regions on lifting wings cannot be treated.

Aeronautical Research Council (Gt. Brit.)
A SUGGESTION FOR A VARIABLE MACH NUMBER SUPERSONIC WIND TUNNEL. P. Bakke. July 1, 1954. 5p. diagrs., photos., tab. ARC 16,906; T.P.432. (Ask for N-48833*)

When a supersonic jet exhausts into a region of lower pressure, part of the resulting flow in the jet is uniform and parallel. The Mach number in this limited portion of the flow is higher than the value attained at the surface of the jet; that is, it is higher than the Mach number reached by a uniform expansion from the pressure at the exit of the jet to the pressure in the region outside the jet. This behavior suggests that it should be possible to achieve an open-jet wind tunnel with a Mach number continuously variable over a certain range by altering the pressure outside the jet. These experiments give some preliminary information on the method of providing the variation in pressure and suggest that it may be obtained with economy in power by using a movable wedge in the tunnel diffuser.

Advisory Group for Aeronautical Research and Development. NOTE ON STRAIN GAUGE RECORDING EQUIPMENT FOR THE R.A.E. INTERMITTENT SUPERSONIC WIND TUNNELS. K. G. Winter and E. J. Petherick, United Kingdom. (Presented at 9th meeting of AGARD Wind Tunnel and Model Testing Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. iv, 11p. diagrs., photos. AGARD Report 64. (Ask for N-52445*)

A description is given of a simple system for photographing, up to 6 times per second, revolution counters driven from strain-gage balance indicators. A further proposed system using punched cards is also described. Results show that, even with comparatively slow strain-gage balance indicators, satisfactory recording of the loads on a model over a wide incidence range can be obtained in a run of 20 seconds duration.

Advisory Group for Aeronautical Research and Development. RECENT RESEARCH ON THE DETERMINATION OF NATURAL MODES AND FREQUENCIES OF AIRCRAFT WING STRUCTURES. John M. Hedgepeth, National Advisory Committee for Aeronautics. (Presented at 3rd meeting of AGARD Structures and Materials Panel, April 10-17, 1956, Washington, D.C.) April 1956. v, 24p. diagrs., photos., tabs. AGARD Report 37. (Ask for N-52446*)

Summarizes and discusses some recent theoretical and experimental studies of the vibrations of aircraft wing structure. Assesses the importance of various secondary effects and outlines methods of including them. Compares experimental values for natural frequencies of box-beam specimens with theoretical calculations and shows that, particularly for the higher modes, good agreement requires the inclusion of secondary effects.

NACA HYPERSONIC ROCKET AND HIGH-TEMPERATURE JET FACILITIES. Paul E. Purser and Aleck C. Bond. (Presented to Wind Tunnel and Model Testing Panel of the Advisory Group for Aeronautical Research and Development, Scheveningen, Holland, July 8-12, 1957). 16p. diagrs., photos. (Ask for N-53173*)

This paper discusses the extension of the rocket-model research of the National Advisory Committee for Aeronautics (NACA) to hypersonic speeds and describes briefly several high-temperature jet facilities assembled by the NACA for research on structures and materials. Of the jets described, one is essentially the exhaust of a ram-jet engine and provides stagnation temperatures up to 3000° F; one is a rocket engine and provides stagnation temperatures up to 4200° F; one is a 4000° F air jet using a ceramic heat exchanger; and one is an electric-arc-heated jet with stagnation temperatures of over 15,000° F.

Polytechnic Institute of Brooklyn.
THE BLASIUS EQUATION WITH THREE-POINT BOUNDARY CONDITIONS. Luigi G. Napolitano. January 1957. 44p. diagrs., tabs. Polytechnic Institute of Brooklyn. PIBAL Report 319. (Ask for N-52311*)

The occurrence of the Blasius equation subject to three-point boundary conditions in a variety of problems involving the mixing of two uniform streams is shown. A solution of this equation, with the third boundary condition applied to the Blasius function itself, is presented by way of a series in terms of the ratio $\lambda = \frac{u_1 - u_2}{u_1}$ where the u_i's are the inviscid streams' velocities. The first three approximations are explicitly expressed in terms of the repeated integrals of the complementary error function ($i^n\mathrm{erfc}\,\eta$) and of the repeated integrals of the square of the functions $i^n\mathrm{erfc}\,\eta$. Pertinent formulas permitting the rapid evaluation of these functions for positive and negative values of the independent variable are developed.

A NEW MICROBALANCE OF QUARTZ FOR WORK UNDER HIGHEST VACUUM. (Eine neue Mikrowaage aus Quarz für Arbeiten im Höchstvakuum.) Herbert Mayer and Klaus Behrndt. June 1957. 10p. diagrs. Translation from Zeitschrift für Physik, v.147, no.4, 1957. (Ask for CN-52538*)

A description is given of a microbalance of quartz - the results of suitable developmental work - which, for an accuracy of up to 1×10^{-8} g, can be built into a highest vacuum apparatus and can there be subjected to all necessary processes. The balance is operated from outside. The instrument is so rugged that it withstands all strains unavoidably occurring during installation, fusion, and baking-out. The balance, its manufacture, and all processes to be followed in taring, etc., are described in all details and the operation of the balance is discussed.

NACA Rept. 1297

NONLIFTING WING-BODY COMBINATIONS WITH CERTAIN GEOMETRIC RESTRAINTS HAVING MINIMUM WAVE DRAG AT LOW SUPERSONIC SPEEDS. Harvard Lomax. 1957. ii, 11p. diagrs. (NACA Rept. 1297. Supersedes TN 3667)

Several variational problems involving optimum wing and body combinations having minimum wave drags for different kinds of geometrical restraints are analyzed. Particular attention is paid to the effect on the wave drag of shortening the fuselage and, for slender axially symmetric bodies, the effect of fixing the fuselage diameter at several points or even of fixing whole portions of its shape.

NACA Rept. 1298

AN ANALYSIS OF THE EFFECTS OF AEROELASTICITY ON STATIC LONGITUDINAL STABILITY AND CONTROL OF A SWEPT-WING AIRPLANE. Richard B. Skoog. 1957. ii, 12p. diagrs. (NACA Rept. 1298. Supersedes RM A51C19)

A theoretical analysis of the effects of aeroelasticity on the stick-fixed static longitudinal stability and elevator angle required for balance of an airplane is presented together with calculated effects for a swept-wing bomber of relatively high flexibility. Although large changes in stability due to certain parameters are indicated for example airplane, the overall stability change after considering all parameters was quite small, compared to the individual effects, due to the counterbalancing of wing and tail contributions. The effect of flexibility on longitudinal control for the example airplane was found to be of little real importance.

NACA RM 57E17

EXPERIMENTAL INVESTIGATION OF CREEP BENDING AND BUCKLING OF THIN CIRCULAR CYLINDRICAL SHELLS. Burton Erickson, Sharad A. Patel, Francis W. French, Samuel Lederman, and N. J. Hoff, Polytechnic Institute of Brooklyn. July 1957. 30p. diagrs., photos., tabs. (NACA RM 57E17)

Forty-three cylinders of 40-inch length and 16-inch diameter, made of 5052-0 aluminum-alloy sheets of 0.032-, 0.040-, 0.051-, and 0.064-inch thickness, were subjected to bending moments constant along the cylinder and in time in an oven which maintained a constant temperature of 500° F during the test. All the cylinders failed by buckling. The time that elapsed between load application and collapse was measured.

CURRENT NACA RESEARCH REPORTS

NACA RM A57F03

PRELIMINARY INVESTIGATION OF THE CHARACTERISTICS OF A TWO-DIMENSIONAL WING AND PROPELLER WITH THE PROPELLER PLANE OF ROTATION IN THE WING-CHORD PLANE. David H. Hickey. August 1957. 12p. diagrs. (NACA RM A57F03)

Qualitative results of an investigation of a propeller rotating in the chord plane of a two-dimensional wing are presented. Severe ground effects below a ground-plane distance of two propeller diameters were noted. Induced loading caused large negative pressure peaks on the wing leading edge. Operation of the propeller at forward speed was limited by propeller blade breakage, indicating an increased stress level in the blades.

NACA RM E57A15

FOREIGN-OBJECT RETENTION AND FLOW CHARACTERISTICS OF RETRACTABLE ENGINE-INLET SCREENS. Fred W. Steffen and Lewis A. Rodert. July 1957. 30p. diagrs., photos. (NACA RM E57A15)

Object-retention and pressure-loss tests were made with two production-model full-scale retractable engine-inlet screens. Turbulence, which dislodged objects from the screens during retraction, and extension and after retraction, and large physical clearances, particularly at the hinge line, were the principal factors which caused the loss of foreign objects. About half of the total-pressure loss through the screen station, with the screens either extended or retracted, was caused by the retraction wells. Methods for improving the retention and pressure-loss characteristics are shown and suggested.

NACA RM E57F11

DROP BURNING RATES OF HYDROCARBON AND NONHYDROCARBON FUELS. Arthur L. Smith and Charles C. Graves. August 1957. 22p. diagrs., photos., tabs. (NACA RM E57F11)

Drop burning rates were determined for single drops of 15 hydrocarbon and nonhydrocarbon fuels. Data were compared with the rates predicted by a theoretical analysis and with the combustion efficiencies of a full-scale, single tubular combustor operating with the same fuels, as determined in a previous investigation. The drop burning rates were proportional to drop diameter. The order of burning rates of the various fuels was generally predicted satisfactorily by the theoretical analysis; however, the absolute values of burning rate obtained were not in complete agreement with those predicted. Combustion efficiency in the turbojet combustor was not related to the variations in drop burning rate.

NACA TN 3289

THE MINIMIZATION OF WAVE DRAG FOR WINGS AND BODIES WITH GIVEN BASE AREA OR VOLUME. Max. A. Heaslet. July 1957. 27p. (NACA TN 3289)

The minimization of wave drag for thin aerodynamic shapes carrying no lift is studied for conditions under which either base area or volume is specified. The problem is reduced to one of determining a two-dimensional harmonic function with known boundary conditions. In several examples the theory is applied to the calculation of the minimum drag and to the final determination of the body shape. For a large family of shapes the minimum drag corresponding to given base area can be determined from an undimensional flow analysis in a duct of known shape.

NACA TN 3781

HANDBOOK OF STRUCTURAL STABILITY. PART I - BUCKLING OF FLAT PLATES. George Gerard and Herbert Becker, New York University. July 1957. iii, 102p. diagrs., tabs. (NACA TN 3781)

The various factors governing the buckling of flat plates are critically reviewed and the results are summarized in a comprehensive series of charts and tables. Numerical values are presented for buckling coefficients of flat plates with various boundary conditions and applied loadings. The effects of plasticity are incorporated in nondimensional buckling charts utilizing the three-parameter description of stress-strain curves.

NACA TN 3782

HANDBOOK OF STRUCTURAL STABILITY. PART II - BUCKLING OF COMPOSITE ELEMENTS. Herbert Becker, New York University. July 1957. 72p. diagrs., tabs. (NACA TN 3782)

The local buckling of stiffener sections and the buckling of plates with sturdy stiffeners are reviewed, and the results are summarized in charts and tables. Numerical values of buckling coefficients are presented for longitudinally compressed stiffener sections of various shapes, for stiffened plates loaded in longitudinal compression and in shear, and for stiffened cylinders loaded in torsion. Although the data presented consist primarily of elastic-buckling coefficients, the effects of plasticity are discussed for a few special cases.

CURRENT NACA RESEARCH REPORTS

NACA TN 3985

PROPELLANT VAPORIZATION AS A CRITERION FOR ROCKET ENGINE DESIGN; CALCULATIONS OF CHAMBER LENGTH TO VAPORIZE A SINGLE n-HEPTANE DROP. Richard J. Priem. July 1957. 41p. diagrs., tab. (NACA TN 3985)

Calculations were made for n-heptane drops using various drop sizes, injection velocities, final gas velocities, initial fuel temperatures, and chamber pressures to show how these variables would affect the vaporization rate and the chamber lengths required to vaporize the drops. The calculations indicate that droplet vaporization may be the controlling process in the combustion zone. The results are correlated for ease in using them for design purposes. The results agree with experimental data obtained previously with a liquid oxygen - heptane rocket.

NACA TN 4040

ESTIMATION OF INCREMENTAL PITCHING MOMENTS DUE TO TRAILING-EDGE FLAPS ON SWEPT AND TRIANGULAR WINGS. Harry A. James and Lynn W. Hunton. July 1957. 31p. diagrs., tab. (NACA TN 4040. Supersedes RM A55D07)

A method is shown by which the incremental pitching moment of swept and triangular wings due to flaps at low speeds can be estimated by using two-dimensional data in conjunction with span-loading theory. Comparisons of estimated and experimental values of flap pitching-moment increments for some 58 cases indicate a mean deviation of about 0.02 C_m. Some two-dimensional flap parameters pertinent to the application of the method are summarized in graphical form.

NACA TN 4041

THE SUBSONIC STATIC AERODYNAMIC CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A TRIANGULAR WING OF ASPECT RATIO 3. I - EFFECTS OF HORIZONTAL-TAIL LOCATION AND SIZE ON THE LONGITUDINAL CHARACTERISTICS. Bruce E. Tinling and Armando E. Lopez. July 1957. 85p. diagrs., photo., tabs. (NACA TN 4041. Supersedes RM A53L15)

Wind-tunnel tests were conducted to evaluate the effects of horizontal-tail location and size on the longitudinal aerodynamic characteristics of an airplane model having a thin triangular wing of aspect ratio 3. The model was tested with horizontal tails, which had areas of either 16.7 or 21.9 percent of the wing area, placed -0.10, 0, 0.10, or 0.20 wing semispan above the wing chord plane, and either 1.2 or 1.5 mean aerodynamic chord behind the moment center. The horizontal tails had aspect ratios of 4 and no sweepback of the 50-percent chord lines. The tests were conducted at a Reynolds number of 2.5 million at Mach numbers from 0.25 to 0.95.

NACA TN 4042

THE SUBSONIC STATIC AERODYNAMIC CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A TRIANGULAR WING OF ASPECT RATIO 3. II - LATERAL AND DIRECTIONAL CHARACTERISTICS. Howard F. Savage and Bruce E. Tinling. August 1957. 82p. diagrs., photo., tabs. (NACA TN 4042. Supersedes RM A55B11)

The effects of vertical-tail size and length on the lateral and directional stability characteristics of both mid- and high-wing airplane arrangements were evaluated. Also evaluated were the directional-control effectiveness of a rudder, and the lateral-control effectiveness of ailerons and of differential deflection of the horizontal-tail surfaces. The tests were conducted at a Reynolds number of 2.5 million at Mach numbers from 0.25 to 0.95.

NACA TN 4043

THE SUBSONIC STATIC AERODYNAMIC CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A TRIANGULAR WING OF ASPECT RATIO 3. III - EFFECTS OF TRAILING-EDGE FLAPS. Bruce E. Tinling and A. V. Karpen. July 1957. 37p. diagrs., photos., tabs. (NACA TN 4043. Supersedes RM A54L07)

Wind-tunnel tests were conducted to find the effects of single-slotted flaps on the longitudinal stability at low speed, the rolling effectiveness of trailing-edge ailerons and of differential deflection of the horizontal tail when the flaps were deflected 40°, and the effect of small deflections of the flaps on the lift-drag ratio at Mach numbers up to 0.95.

NACA TN 4044

GROUND EFFECTS ON THE LONGITUDINAL CHARACTERISTICS OF TWO MODELS WITH WINGS HAVING LOW ASPECT RATIO AND POINTED TIPS. Donald A. Buell and Bruce E. Tinling. July 1957. 48p. diagrs., photos., tabs. (NACA TN 4044. Supersedes RM A55E04)

Wind-tunnel tests were conducted to determine the ground effects on a tailless model with a wing of aspect ratio 2 and infinite taper, and on a tailed model with a triangular wing of aspect ratio 3, with flaps. Control-surface hinge moments were measured on the tailless model. The results are compared with the predictions of the theory of Tani, et al.

CURRENT NACA RESEARCH REPORTS

NACA TN 4064

REVIEW AND INVESTIGATION OF UNSATISFACTORY CONTROL CHARACTERISTICS INVOLVING INSTABILITY OF PILOT-AIRPLANE COMBINATION AND METHODS FOR PREDICTING THESE DIFFICULTIES FROM GROUND TESTS. William H. Phillips, B. Porter Brown, and James T. Matthews, Jr. August 1957. 57p. diagrs. (NACA TN 4064. Supersedes RM L53F17a)

A number of examples are presented of control difficulties which appear to result from a tendency for dynamic instability of the combination of the pilot, control system, and airplane. These difficulties have occurred in both conventional and power control systems. Tests of a bomber and a fighter airplane equipped with hydraulic-power controls have been made to study this problem. The effect of friction in the control valves of the power control systems is discussed. An analytical study of the problem and a method of detecting such control difficulties by means of ground simulator tests are presented.

NACA TN 4067

APPROXIMATE ANALYSIS OF EFFECTS OF LARGE DEFLECTIONS AND INITIAL TWIST ON TORSIONAL STIFFNESS OF A CANTILEVER PLATE SUBJECTED TO THERMAL STRESSES. Richard R. Heldenfels and Louis F. Vosteen. August 1957. 36p. diagrs. (NACA TN 4067)

An approximate analysis of the nonlinear effects of initial twist and large deflections ón the torsional stiffness of a cantilever plate subjected to a nonuniform temperature distribution is presented. The Von Kármán large-deflection equations are satisfied through the use of a variational principle. The results show that initial twist and applied moments can have significant effects on the changes in stiffness produced by nonuniform heating, particularly in the region of the buckling temperature difference. Results calculated by this approximate analysis are in satisfactory agreement with measured torsional deformations and changes in natural frequency.

NACA TN 4068

EFFECTS OF BLADE PLAN FORM ON FREE-SPACE OSCILLATING PRESSURES NEAR PROPELLERS AT FLIGHT MACH NUMBERS TO 0.72. Max C. Kurbjun. August 1957. 20p. diagrs., photos., tabs. (NACA TN 4068)

Comparisons are made of the free-space oscillatory pressures near the tips of propellers with rectangular and tapered blade plan forms. Measurements were made at a single radial station and at three axial positions (ahead of, in the plane of, and behind the propeller disk). The effects of propeller blade plan form are shown as comparisons of the noise emitted from the rectangular- and tapered-blade propellers with changes in operating parameters of Mach number, power, and engine speed.

NACA TN 4070

FLIGHT-TEST INVESTIGATION ON THE LANGLEY CONTROL-LINE FACILITY OF A MODEL OF A PROPELLER-DRIVEN TAIL-SITTER-TYPE VERTICAL-TAKE-OFF AIRPLANE WITH DELTA WING DURING RAPID TRANSITIONS. Robert O. Schade. August 1957. 19p. diagrs., photo., tab. (NACA TN 4070)

A flight-test investigation has been made on the Langley control-line facility to determine the longitudinal stability and control characteristics of a model of a propeller-driven tail-sitter-type vertical-take-off airplane with delta wing during rapid transitions from hovering flight to forward flight and back to hovering. The investigation showed that the facility was generally satisfactory for investigating the characteristics of vertical-take-off models during rapid transitions. It was found that rapid transitions from hovering to forward flight could be performed fairly easily and that the transitions from forward flight to hovering flight were more difficult to perform.

NACA TN 4072

EXPERIMENTAL INVESTIGATION OF ATTENUATION OF STRONG SHOCK WAVES IN A SHOCK TUBE WITH HYDROGEN AND HELIUM AS DRIVER GASES. Jim J. Jones. July 1957. 24p. diagrs., photo. (NACA TN 4072)

An experimental investigation has been made of the attenuation of strong shock waves in air in a shock tube. Time-history measurements were made of the static pressure at several stations in the wall of the tube. The internal diameter of the tube is 3.75 inches. Shock-wave-velocity data were taken for a distance along the tube of about 120 feet. The range of the shock-wave Mach number covered was from 5 to 10-1/2 and the initial pressure ahead of the shock wave varied from 5 to 100 millimeters of mercury. Hydrogen and helium were used as driver gases.

AN INVESTIGATION INTO THE METALLURGICAL FACTORS AFFECTING THE FATIGUE PROPERTIES OF SOME ALUMINIUM ALLOYS. INTERIM REPORT. R. W. George and P. J. E. Forsyth. November 1956. 23p. diagrs., photos., tabs. RAE Tech.Note Met. 254. (Ask for N-48941*)

The fatigue and tensile properties of a number of high purity aluminium alloys have been determined. The compositions of these alloys have been chosen to investigate specific metallographic structures. It was found that additions of iron up to 0.1 percent improved the fatigue and tensile properties of aluminium with little deterioration of the $\frac{F.L.}{U.T.S.}$ ratio. Additions of copper and zinc were made to aluminium 5 percent magnesium alloy resulting in improvements in tensile properties with a corresponding improvement in fatigue properties.

THE WAVE DRAG OF NON-LIFTING COMBINATIONS OF THIN WINGS AND "NON-SLENDER" BODIES. L. M. Sheppard. March 1957. 26p. diagrs. RAE Tech.Note Aero 2496.
(Ask for N-48943*)

The methods of wave drag estimation known as the area rule and transfer rule are restricted to non-lifting combinations of thin wings and slender bodies. The Lomax-Heaslet multipole method is applicable to configurations with "nonslender" fuselages, represented by an axial distribution of multipoles. However, it is not entirely satisfactory and an alternative multipole method is presented here. This is based upon the assumption, fundamental to the area rule and the transfer rule, that the effect on the wave drag of the interference velocity potential, due to the interaction between the exposed wing and the fuselage, is negligible. An investigation of the validity of this fundamental assumption, based on existing theoretical and experimental results, is given. The application of the multipole method to fuselage design for low combination wave drag is discussed with special reference to an elliptic wing-body combination.

N-48944*

Royal Aircraft Establishment (Gt. Brit.)
SOME THICKNESS DISTRIBUTIONS FOR NARROW WINGS. W. T. Lord and Barbara Green. February 1957. 29p. diagrs., tab. RAE Tech.Note Aero 2495. (Ask for N-48944*)

An outline is given of a method for designing thickness distributions for narrow wings, particularly wings with straight unswept trailing edges. The method uses inviscid flow theory to design for lowish zero-lift wave drag in such a way that possible effects of boundary layers are taken into account in accordance with the ideas of Küchemann and Weber. For clarity, only delta wings with diamond cross sections and sharp leading edges are considered in detail here. The essence of the method is that narrow wings should be designed to have specified cross-sectional area distributions; for wings with sharp leading edges it is convenient that these specified area distributions should be given by polynomials, and some examples are described. The method is not founded on a rigorous theoretical analysis, but supporting evidence is provided by some calculations of pressure distributions by Weber, and confirmation is to be sought experimentally.

Aeronautical Research Council (Gt. Brit.)
A THEORY OF THE STABILITY OF PLANE SHOCK WAVES. N. C. Freeman. September 6, 1954. 29p. diagrs. ARC 17,029; FM 2122.
(Ask for N-48945*)

The stability of form of a plane shock, obtained when a "corrugated" piston is moved impulsively from rest with constant velocity, is investigated mathematically. Linearization of the problem is accomplished by assuming the corrugations to be small. The solution is built up by methods of Fourier analysis from "conefield" solutions of the analogous "wedge"-shaped piston problem, solved by methods due to Lighthill. The plane shock is shown to be stable, perturbations from plane decaying with time in an oscillatory manner like $t^{-3/2}$ for large ta_1/λ (where a_1 is the velocity of sound behind the shock and λ the wavelength of the corrugations)

N-48946*

Aeronautical Research Council (Gt. Brit.)
VISCOUS EFFECTS ON FLATTENED PITOT TUBES AT LOW SPEEDS. F. A. MacMillan. October 14, 1954. 5p. diagrs., tab. ARC 17,106; FM 2081a.
(Ask for N-48946*)

Measurements were made of the pressures in flattened, blunt-nosed pitot tubes, in an air stream at Reynolds numbers from 13 to 1,000 (based on the external height of the tube). Three tubes were used having cross sections with ratios of width to height (W/H) of 3, 7, and 11. The results are expressed in terms of a pressure coefficient, C_p. It was found that C_p decreased below 1 for all the tubes, although earlier measurements had shown that this did not occur with circular tubes. The maximum decrease was about 1.6 percent at a Reynolds number of 65.

UNPUBLISHED PAPERS

N-52740*

MODEL-TESTING METHODS IN AERONAUTICS. (Modell-Messverfahren der Flugtechnik.) Rudolf Schmidt and Paul Klages. January 1957. 92p. diagrs., photos., tabs. Translation from Zeitschrift für Flugwissenschaften, v. 3, no. 7, July 1955, p. 169-205. (Ask for N-52740*)

Beginning with the various techniques of model testing most commonly used in wind tunnels and the test conditions which have to be observed in order to satisfy the law of similitude, the technical equipment required is briefly discussed and the accuracy and reliability that can be expected from such measurements are indicated. A description is given of towing techniques and free-flight methods of various types. Characteristics of the various techniques regarding type of problem, range of applicability, technical requirements, and reliability of measurements are compared with the wind tunnel leading to the conclusion that the model-towing method with carrier sled or carrier airplane offers the greatest possibilities for replacing large-size wind tunnels.

FLIGHT MEASUREMENTS OF THE HORIZONTAL-TAIL LOADS ON A SWEPT-WING FIGHTER AIRPLANE AT TRANSONIC SPEEDS. Melvin Sadoff. November 1953. 58p. diagrs., photo., tab. (NACA RM A53G10)

Flight measurements of the horizontal-tail loads on a swept-wing fighter airplane at Mach numbers of 0.6 to 1.03 at 35,000 feet have indicated critical flight regions for balancing, maneuvering, and buffeting tail loads. The critical flight region for balancing loads was at the highest test Mach number of about 1.03 at the highest load factor attained. The maneuvering and buffeting load increments were generally critical at Mach numbers below about 0.90. The buffet tail-load increments were relatively small compared to the balancing and maneuvering tail loads.

NACA RM A55E31

INVESTIGATION OF SOME WAKE VORTEX CHARACTERISTICS OF AN INCLINED OGIVE-CYLINDER BODY AT MACH NUMBER 1.98. Leland H. Jorgensen and Edward W. Perkins. August 1955. 47p. diagrs., photos., tabs. (NACA RM A55E31)

For a body consisting of a fineness-ratio-3 ogival nose tangent to a cylindrical afterbody 7.3 diameters long, pitot-pressure distributions in the flow field, pressure distributions over the body, and downwash distributions along a line through the vortex centers have been measured for angles of attack to 20°. The Reynolds numbers, based on body diameter, were 0.15×10^6 and 0.44×10^6. Comparisons of computed and measured vortex paths and downwash distributions are made.

NACA RM A55G11

DEVELOPMENT OF A HIGH-VELOCITY FREE-FLIGHT LAUNCHER - THE AMES LIGHT-GAS GUN. A. C. Charters, B. Pat Denardo, and Vernon J. Rossow. December 1955. (i), 97p. diagrs., photos., tabs. (NACA RM A55G11)

A light-gas gun has been developed at the Ames Aeronautical Laboratory to launch small models at very high velocities for free-flight aerodynamic tests. The design of the gun and the analysis of its performance are presented. The results of the initial firing trials are discussed. The firing trials showed good agreement between measured and predicted velocities and pressures and a velocity of 15,400 ft/sec was reached. It is concluded that the gun is a satisfactory launcher for high-velocity free-flight tests.

NACA RM A55I21

A DESCRIPTION OF THE AMES 2- BY 2-FOOT TRANSONIC WIND TUNNEL AND PRELIMINARY EVALUATION OF WALL INTERFERENCE. Joseph M. Spiegel and Leslie F. Lawrence. January 1956. 65p. diagrs., photo. (NACA RM A55I21)

The Ames 2- by 2-foot wind tunnel, a research facility in which the Mach number can be varied continuously up to 1.4, is described. It utilizes a flexible nozzle to produce supersonic flow and a form of perforated test section to alleviate wall interference. Wall interference is evaluated from tests of three different sizes of a wing-body model, and it is concluded to be small when the model frontal area is less than 1/2 percent of the test-section cross-sectional area.

NACA RM A56E24

FULL-SCALE WIND-TUNNEL TESTS OF A 35° SWEPTBACK-WING AIRPLANE WITH HIGH-VELOCITY BLOWING OVER THE TRAILING-EDGE FLAPS - LONGITUDINAL AND LATERAL STABILITY AND CONTROL. William H. Tolhurst, Jr., and Mark W. Kelly. October 1956. 64p. diagrs., photo., tabs. (NACA RM A56E24)

A wind-tunnel investigation was conducted to determine the effects of a blowing-type boundary-layer-control flap on the longitudinal and lateral stability and control of a 35° sweptback-wing airplane with standard aileron controls. As alternatives for the standard ailerons, tests were also made of the following types of lateral control devices: split-flap-type spoilers, differentially deflected flaps, and differential amounts of blowing over the flaps. The results are presented as six-component force data measured at a Reynolds number of 7.5×10^6.

NACA RM A56G19

WIND-TUNNEL TESTS OF BLOWING BOUNDARY-LAYER CONTROL WITH JET PRESSURE RATIOS UP TO 10 ON THE TRAILING-EDGE FLAPS OF A 35° SWEPTBACK WING AIRPLANE. Mark W. Kelly and Jeffrey H. Tucker. October 1956. 24p. diagrs., photo., tab. (NACA RM A56G19)

A full-scale wind-tunnel investigation on a 35° swept-wing airplane showed that the lift increment due to blowing high-velocity air jets over the wing trailing-edge flaps could be adequately correlated with the jet momentum for various jet nozzle heights and with jet pressure ratios ranging from subcritical to 9.5.

NACA RM E50G10

EFFECT OF FUEL VOLATILITY ON ALTITUDE STARTING LIMITS OF A TURBOJET ENGINE. H. D. Wilsted and J. C. Armstrong. September 11, 1950. 27p. diagrs., tabs. (NACA RM E50G10)

The effect of fuel volatility on altitude starting limits of an axial-flow-compressor-type turbojet engine was investigated using fuels with Reid vapor pressures of 1.1 and 5.4 pounds per square inch. At flight Mach numbers from 0.40 to 0.85, the AN-F-58 fuel allowed consistent windmilling at altitudes 2000 to 8000 feet higher than was obtained with the 1.1-pound Reid vapor pressure fuel. At a flight Mach number of 0.25, ignition could not be established at any altitude with the lower volatility fuel.

NACA RM E51B12

NACA INVESTIGATIONS OF ICING-PROTECTION SYSTEMS FOR TURBOJET-ENGINE INSTALLATIONS. Uwe von Glahn, Edmund E. Callaghan, and Vernon H. Gray. May 2, 1951. (ii), 83p. diagrs., photos. (NACA RM E51B12)

A summary is presented of the investigations made in flight and in wind tunnels at the NACA Lewis laboratory to determine which components of turbojet engines are most critical in icing conditions and to evaluate several icing-protection methods. Complete removal or retraction of compressor-inlet screens upon entering icing conditions is recommended. Surface heating appears to be the most acceptable icing-protection method, although hot-gas bleedback offers a simple method for obtaining icing protection on some installations.

NACA RM E51G06

INVESTIGATION AT MACH NUMBER 1.88 OF HALF OF A CONICAL-SPIKE DIFFUSER MOUNTED AS A SIDE INLET WITH BOUNDARY-LAYER CONTROL. H. Fred Goelzer and Edgar M. Cortright, Jr. September 1951. 38p. diagrs., photos. (NACA RM E51G06)

Experimental investigation was conducted at Mach number 1.88 to determine performance characteristics of half a 50°-conical-spike inlet mounted on a flat plate. Initial boundary layer was removed upstream of inlet by a ram-type scoop of variable height. Initial boundary-layer thickness was also varied. With complete removal of initial boundary layer, total-pressure recovery of approximately 89 percent was obtained. Allowing all initial boundary layer to flow into the inlet lowered the inlet total-pressure recovery to approximately 70 percent. Several alternative boundary-layer-removal systems were investigated which decreased the adverse effect of operating the ram scoop subcritically.

NACA RM E51G19

EXPERIMENTAL INVESTIGATION OF A 16-INCH IMPULSE-TYPE SUPERSONIC-COMPRESSOR ROTOR. Guy N. Ullman, Melvin J. Hartmann, and Edward R. Tysl. October 1951. 29p. diagrs., photos. (NACA RM E51G19)

Performance data and characteristics of a 16-inch impulse-type supersonic-compressor rotor are presented. The experimental portion of this investigation was conducted in Freon-12. A peak pressure ratio of 3.6 was obtained with an adiabatic efficiency of 0.80 at design conditions. Performance was continuous from impulse operation, at open throttle, to shock-in-rotor operation at the stall condition.

NACA RM E52E02

PERFORMANCE CHARACTERISTICS AT MACH NUMBERS TO 2.0 OF VARIOUS TYPES OF SIDE INLETS MOUNTED ON FUSELAGE OF PROPOSED SUPERSONIC AIRPLANE. I - TWO-DIMENSIONAL COMPRESSION-RAMP INLETS WITH SEMICIRCULAR COWLS. Alfred S. Valerino. July 1952. 43p. diagrs., photos., tab. (NACA RM E52E02)

An experimental investigation was conducted at Mach numbers of 0, 0.63, and 1.5 to 2.0 to determine the performance of semicircular inlets located on the fuselage of a proposed aircraft. The inlets utilized two-dimensional compression ramps and ram-type scoops for boundary-layer removal. Results of the investigation indicated that significant gains in pressure recovery with slight increases in drag were obtained by removal of the entire boundary layer upstream of the inlets. At zero forward speed and at a Mach number of 0.63, use of a sharp-lip cowling penalized the pressure recoveries. In the supersonic Mach number range, the rounded-lip and sharp-lip inlets had comparable pressure recoveries. However, serious drag penalties were incurred with the rounded-lip cowling at a Mach number of 2.0. A large part of the losses in pressure recovery at angles of attack was attributed to the decrease in effective boundary-layer removal.

NACA RM E52G02

EFFECTS ON THE WEIGHT-FLOW RANGE AND EFFICIENCY OF A TYPICAL AXIAL-FLOW COMPRESSOR INLET STAGE THAT RESULT FROM THE USE OF A DECREASED BLADE CAMBER OR DECREASED GUIDE-VANE TURNING. Robert J. Jackson. September 1952. 41p. diagrs., photos. (NACA RM E52G02)

A single-stage compressor investigation was made to improve the weight-flow-range characteristics of a typical inlet stage by increasing the usable angle-of-attack range by reduction in camber and by reduction of the rate of change of angle of attack with weight flow. It was found that the range is determined by the static-pressure rise at the rotor-tip section and by the absolute inlet-air angle which determines to a large extent the rate of change of angle of attack with weight flow. It was found that decreased camber had very little effect on weight-flow range, whereas decreased guide-vane turning resulted in a large decrease in the rate of change of angle of attack with weight flow as well as in a reduction of the static-pressure rise across the rotor-tip section.

NACA RM E52G08

PERFORMANCE CHARACTERISTICS AT MACH NUMBERS TO 2.0 OF VARIOUS TYPES OF SIDE INLETS MOUNTED ON FUSELAGE OF PROPOSED SUPERSONIC AIRPLANE. II - INLETS UTILIZING HALF OF A CONICAL SPIKE. J. L. Allen and P. C. Simon. September 1952. 49p. diagrs., photos., tab. (NACA RM E52G08)

The performance of semicone inlets located on a fuselage was investigated at Mach numbers of 0, 0.63, and 1.5 to 2.0. The inlets utilized a half spike for compression and ram-type boundary-layer removal scoops. Peak pressure recoveries from 0.86 to 0.95 were obtained at Mach numbers from 2.0 to 1.5 at an angle of attack of 3° with complete removal of the fuselage boundary layer forward of the inlets. Translating the semicone to an aft position increased the captured mass flow with no change in pressure recovery at a Mach number of 1.5; however, at Mach numbers of 1.9 and 2.0, the stable subcritical operating range of the inlet was severely limited by pulsing. Sweeping back the leading edge of the splitter plate used to separate the boundary layer and flow entering the main inlet increased the stable subcritical operating range of the inlet at a Mach number of 2.0 for angles of attack from 0° to 9°. At a Mach number of 0.63, a pressure recovery of 0.97 was attained for critical flow. At zero forward velocity, a large vena contracta was observed which may limit the performance at take-off unless auxiliary inlets are used.

NACA RM E52G23

INVESTIGATION AT MACH NUMBER 2.93 OF HALF OF A CONICAL-SPIKE DIFFUSER MOUNTED AS A SIDE INLET WITH BOUNDARY-LAYER CONTROL. Thomas G. Piercy and Harry W. Johnson. September 1952. 39p. diagrs., photos. (NACA RM E52G23)

An experimental investigation was conducted at Mach number 2.93 to determine performance characteristics of half of a 60° conical-spike inlet mounted on a flat plate. Initial boundary layer was removed upstream of the inlet by a ram-type scoop of variable height. The inlet was operated in the presence of both turbulent and laminar boundary layers. With removal of the initial boundary layer, total pressure recoveries of 51.5 and 45.8 percent were obtained for the turbulent and laminar boundary layers, respectively. Allowing all the initial boundary layer to enter the inlet reduced the pressure recovery to approximately 40 percent for both cases. Inlet pressure recoveries with the laminar boundary layer were generally lower than those obtained with the turbulent boundary layer because of the reduced scoop-mass-flow capture for the laminar boundary layer.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E52H20

PERFORMANCE CHARACTERISTICS AT MACH NUMBERS TO 2.00 OF VARIOUS TYPES OF SIDE INLETS MOUNTED ON FUSELAGE OF PROPOSED SUPERSONIC AIRPLANE. III - NORMAL-WEDGE INLET WITH SEMICIRCULAR COWL. Fred T. Esenwein. October 1952. 43p. diagrs., photos. (NACA RM E52H20)

The performance characteristics of side inlets which utilize two-dimensional compression wedges mounted normal to the fuselage surface were investigated with ram-type scoops for partial removal of the boundary layer. The research was conducted over a range of angles of attack at Mach numbers of 0, 0.63, and 1.50 to 2.00. Inlet pressure recoveries measured at the design angle of attack were substantially higher at the supersonic speeds than the recoveries obtained with comparable ramp and spike-type inlets. Sensitivity to cross-flow effects due to the particular circumferential location of the inlets, however, resulted in severe decreases in pressure recovery at angles of attack. At a Mach number of 0.63 pressure recoveries of the order of 0.96 were obtained for mass-flow ratios of approximately unity, whereas at take-off, very large losses in inlet performance were noted over the range of inlet mass flows.

NACA RM E53G09

EFFECT OF CIRCUMFERENTIAL LOCATION ON ANGLE OF ATTACK PERFORMANCE OF TWIN HALF-CONICAL SCOOP-TYPE INLETS MOUNTED SYMMETRICALLY ON THE RM-10 BODY OF REVOLUTION. Alfred S. Valerino, Donald B. Pennington, and Donald J. Vargo. September 1953. 37p. diagrs., photos. (NACA RM E53G09)

An experimental investigation to determine the effects of circumferential inlet location on the performance of twin half-conical scoop-type inlets with and without boundary-layer removal was conducted at Mach numbers 1.49, 1.79, and 1.99 through an angle-of-attack range from 0° to 10°. The twin inlets were mounted symmetrically on the NACA RM-10 body of revolution at four circumferential locations at the station of maximum diameter.

NACA RM E53G10

INVESTIGATION OF TRANSLATING-SPIKE SUPERSONIC INLET AS MEANS OF MASS-FLOW CONTROL AT MACH NUMBERS OF 1.5, 1.8, AND 2.0. Gerald C. Gorton. October 1953. 23p. diagrs., photos., tabs. (NACA RM E53G10)

In order to check the practicability of a translating-spike inlet, an investigation was conducted in the 8- by 6-foot supersonic wind tunnel on a 50° conical-spike inlet at Mach numbers of 1.5, 1.8, and 2.0 over a range of angle of attack from 0° to 9°. The additive drag penalty associated with inlet mass-flow spillage was significantly reduced by using a translating-spike inlet rather than a fixed-geometry inlet. However, the total-pressure recovery of this translating-spike inlet with supersonic spillage was less than the total-pressure recovery of the fixed-geometry inlet at the same mass-flow spillage. Indications of the improvement in performance of a turbojet installation by means of mass-flow control with this specific variable-geometry inlet are included.

NACA RM E53G16

EVALUATION OF EFFECTS OF RANDOM PERMEABILITY VARIATIONS ON TRANSPIRATION-COOLED SURFACES. Jack B. Esgar and Hadley T. Richards. November 1953. 59p. diagrs., photos. (NACA RM E53G16)

An analytical investigation was conducted to evaluate the effects of random permeability variations in transpiration-cooled surfaces on surface temperatures and coolant flows for ranges of temperature and Reynolds number that are of particular interest for gas-turbine blades. Experimental measurements of flow through small orifices and through an experimental blade were used for partial verification of the analytical investigation, which showed that considerable care is required to minimize random permeability variations in gas-turbine blades. In order to keep blade temperature variations to less than ±100° F, random permeability variations of not over ±6 to 10 percent could be tolerated. The results of this and other investigations were used to provide recommended design features for transpiration-cooled turbine blades.

NACA RM E54G27a

INVESTIGATION OF SUPERSONIC-COMPRESSOR ROTORS DESIGNED WITH EXTERNAL COMPRESSION. Lawrence J. Jahnsen and Melvin J. Hartmann. September 1954. 41p. diagrs., photos. (NACA RM E54G27a)

A 16-inch-diameter external-compression shock-in-rotor type supersonic compressor employing the spike diffuser principle, designed with isentropic compression and modified to reduce the external compression, obtained pressure ratios of 2.20 and 2.27, adiabatic efficiencies of 0.72 and 0.76, and equivalent weight flows of 21.4 and 23.2 pounds per second, respectively. A method for computation of the approximate losses at the rotor entrance section of external-compression supersonic compressors is presented.

NACA RM E54I03

INVESTIGATION OF POROUS GAS-HEATED LEADING-EDGE SECTION FOR ICING PROTECTION OF A DELTA WING. Dean T. Bowden. January 1955. 54p. diagrs., photos., tab. (NACA RM E54I03)

An investigation was conducted in the NACA Lewis icing research tunnel to determine heating requirements and characteristics of a gas-heated porous leading-edge system for anti-icing of a delta wing. Adequate icing protection was obtained for all icing conditions investigated. Large savings in gas flow may be realized by sealing half the upper-surface porous area. Gas flow through the porous area caused only a slight increase in airfoil drag and had no appreciable effect on airfoil pressure distribution. Glaze-ice formations on the unheated airfoil caused rapid increases in section drag.

NACA RM E56B23

HEAT REQUIREMENTS FOR ICE PROTECTION OF A CYCLICALLY GAS-HEATED, 36° SWEPT AIRFOIL WITH PARTIAL-SPAN LEADING-EDGE SLAT. Vernon H. Gray and Uwe H. von Glahn. May 1956. 73p. diagrs., photos., tabs. (NACA RM E56B23)

Heating requirements for satisfactory cyclic de-icing over a wide range of icing and operating conditions have been obtained for a gas-heated, 36° swept airfoil with a partial-span leading-edge slat. Comparisons of heating requirements were made between the slatted and unslatted portions of the airfoil and between cyclic de-icing and continuous anti-icing. Cyclic de-icing systems with and without leading-edge ice-free parting strips were also evaluated.

NACA RM L51G27

FREE-FLIGHT MEASUREMENTS AT MACH NUMBERS FROM 0.7 TO 1.6 OF SOME EFFECTS OF AIRFOIL-THICKNESS DISTRIBUTION AND TRAILING-EDGE ANGLE ON AILERON ROLLING EFFECTIVENESS AND DRAG FOR WINGS WITH 0° AND 45° SWEEPBACK. E. M. Fields and H. Kurt Strass. October 1951. 63p. diagrs., photos., tab. (NACA RM L51G27)

Symmetrical 6-percent-thick circular-arc airfoils, having an aspect ratio of 3.7 and 0.2-chord full-span plain flap-type sealed ailerons, were modified in thickness distribution to produce a range of trailing-edge angles from 0° to about 30°. Wing-aileron rolling effectiveness and drag, for unswept and 45° sweptback wings, were obtained over the Mach number range from 0.7 to 1.6 by means of rocket propelled test vehicles in free flight. In addition, data from previous tests are presented to show the effect of trailing-edge angle on wing-aileron rolling effectiveness for various profile shapes and for thickness ratios of 3 percent, 6 percent, and 9 percent.

NACA RM L51H10

CHARACTERISTICS OF A TRANSONIC TEST SECTION WITH VARIOUS SLOT SHAPES IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Ray H. Wright and Virgil S. Ritchie. October 1951. 35p. diagrs., photo. (NACA RM L51H10)

A description is presented of the design and operational characteristics of a large slotted transonic wind tunnel for Mach numbers continuously variable up to approximately 1.14. The flow characteristics for a number of slot shapes are discussed.

NACA RM L51K14

CALIBRATION OF THE SLOTTED TEST SECTION OF THE LANGLEY 8-FOOT TRANSONIC TUNNEL AND PRELIMINARY EXPERIMENTAL INVESTIGATION OF BOUNDARY-REFLECTED DISTURBANCES. Virgil S. Ritchie and Albin O. Pearson. July 1952. 87p. diagrs., photos. (NACA RM L51K14)

The surveys and calibration of the nearly uniform transonic flow in the slotted test section of the Langley 8-foot transonic tunnel at stream Mach numbers up to about 1.14 are described. The flow characteristics with a typical nonlifting model in the slotted test section are illustrated. The effects of boundary interference on pressure distributions and body-drag coefficients measured for the model in the slotted test section are shown to be negligible at subsonic Mach numbers and at the higher supersonic Mach numbers attained; the nature and approximate magnitude of boundary-interference effects at low supersonic Mach numbers are discussed. Experimental information concerning model lengths for interference-free supersonic testing and locations of detached shock waves ahead of axially symmetric bodies are presented.

NACA RM L52E01

AIR-FLOW AND POWER CHARACTERISTICS OF THE LANGLEY 16-FOOT TRANSONIC TUNNEL WITH SLOTTED TEST SECTION. Vernon G. Ward, Charles F. Whitcomb, and Merwin D. Pearson. July 1952. 50p. diagrs., photos. (NACA RM L52E01)

The operational and flow characteristics of the redesigned and repowered Langley 16-foot transonic tunnel are presented through the transonic Mach number range continuously variable to 1.08. The effects of slot plan form, wall divergence, and diffuser entrance shape upon the flow and power characteristics are presented.

NACA RM L52E20

AN INVESTIGATION OF THE STREAM-TUBE POWER LOSSES AND AN IMPROVEMENT OF THE DIFFUSER-ENTRANCE NOSE IN THE LANGLEY 8-FOOT TRANSONIC TUNNEL. Richard T. Whitcomb, Melvin M. Carmel, and Francis G. Morgan, Jr. August 1952. 70p. diagrs., photos., tabs. (NACA RM L52E20)

Total-pressure, total-temperature, and static pressure surveys have been obtained at a number of stations in the slotted test section and diffuser of the Langley 8-foot transonic tunnel with early and improved diffuser-entrance noses installed at the ends of the slots. The results of these surveys and the development of the improved noses are described.

NACA RM L52G09

PRELIMINARY INVESTIGATION OF THE LOW-AMPLITUDE DAMPING IN PITCH OF TAILLESS DELTA- AND SWEPT-WING CONFIGURATIONS AT MACH NUMBERS FROM 0.7 TO 1.35. Charles T. D'Aiutolo and Robert N. Parker. August 1952. 27p. diagrs., photos., tab. (NACA RM L52G09)

A flight test was conducted using four tailless rocket-propelled models of low-aspect-ratio configurations, a 45° delta-wing configuration having NACA 63A010 airfoil sections, a 45° delta-wing configuration having NACA 63A006 airfoil sections, a 37.5° swept-tapered-wing configuration having NACA 64_1A012 airfoil sections, and a 39° swept-tapered-wing configuration having NACA 64A006 airfoil sections. Static and dynamic longitudinal stability and drag characteristics are presented throughout a Mach number range of 0.70 to 1.35.

NACA RM L52G14a

A PRESSURE-DISTRIBUTION INVESTIGATION OF A FINENESS-RATIO-12.2 PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT M = 1.59 AND ANGLES OF ATTACK UP TO 36°. Morton Cooper, John P. Gapcynski, and Lowell E. Hasel. October 1952. 89p. diagrs., photos., tabs. (NACA RM L52G14a)

A pressure-distribution investigation of a parabolic body of revolution with a fineness ratio of 12.2 has been conducted in the Langley 4- by 4-foot supersonic tunnel at a Mach number of 1.59 and a Reynolds number of 3.6×10^6 for angles of attack from 0° to 36°. The data are presented in terms of pressures, local section coefficients, and overall body coefficients. In the low-incidence range, the pressures were well predicted by potential theory except on the leeward side of the body above an angle of attack of 5° where the pressures were affected by cross-flow separation. In the low-incidence range, the normal-force coefficient of the body was underestimated and the axial force predicted reasonably well by potential theory. Application of viscous-cross-flow concepts improved the agreement. The center of pressure was rearward of either the potential or cross-flow estimate.

NACA RM L52G23

EFFECTS OF WING ELASTICITY ON THE AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK-WING-FUSELAGE COMBINATION MEASURED IN THE LANGLEY 8-FOOT TRANSONIC TUNNEL. Robert S. Osborne and John P. Mugler, Jr. September 1952. 27p. diagrs., photos. (NACA RM L52G23)

A 45° sweptback-wing-fuselage configuration has been tested with identical aluminum and steel wings at Mach numbers from 0.6 to 1.13 for angles of attack up to 20° to determine effects of wing elasticity. Dynamic pressures varied from 400 to 850 pounds per square foot. Lift, drag, pitching moment, and base pressure were measured and some comparisons with calculated results are included.

NACA RM L52H22

AN INVESTIGATION OF SOME FACTORS AFFECTING THE DRAG OF RELATIVELY LARGE NONLIFTING BODIES OF REVOLUTION IN A SLOTTED TRANSONIC WIND TUNNEL. Robert E. Pendley and Carroll R. Bryan. January 1953. 52p. diagrs., photos., tabs. (NACA RM L52H22)

In a study of some factors affecting the drag of relatively large nonlifting bodies of revolution in a slotted transonic wind tunnel, measurements of tunnel wall and model surface-pressure distributions and comparisons of pressure and force drags are presented for a 66-inch body of revolution of 8-inch diameter and a half-scale model of that body. Effects of tunnel boundary interference on the data are discussed for an angle of attack of 0° and for a Mach number range of 0.60 to 1.125. Boundary interference was found to be negligible at subsonic Mach numbers, but large boundary effects were found at some supersonic Mach numbers.

NACA RM L53D30b

INVESTIGATION OF A HALF-CONICAL SCOOP INLET MOUNTED AT FIVE ALTERNATE CIRCUMFERENTIAL LOCATIONS AROUND A CIRCULAR FUSELAGE. PRESSURE-RECOVERY RESULTS AT A MACH NUMBER OF 2.01. Lowell E. Hasel, John L. Lankford, and A. W. Robins. June 1953. 41p. diagrs., photos., tab. (NACA RM L53D30b)

The effects of inlet circumferential position around the fuselage on the characteristics of a half-conical scoop inlet having a 24.6° half-angle cone have been investigated in the Langley 4- by 4-foot supersonic pressure tunnel. Pressure-recovery results have been obtained at a Mach number of 2.01 for a fixed boundary-layer-bleed height which was 60 percent of the boundary-layer thickness at an angle of attack of 0°, and for cowling position parameters of 42.4° and 38.0°. The inlet had a capture area equal to 24.9 percent of the basic-fuselage frontal area. The angle of attack was varied from 0° to 12°. The most favorable pressure-recovery characteristics at angles of attack were obtained with the inlet located on the bottom of the fuselage where the maximum recovery increased from a value of 81 percent at an angle of attack of 0° to 87 percent at 12°. In general,

the pressure recovery decreased with increasing angle of attack for all other inlet locations. At a given angle of attack the pressure recovery decreased as the inlet location was progressively moved from the bottom to the top of the fuselage. Stable subcritical operation of the inlet with nearly constant pressure recovery was obtained for inlet mass-flow ratios from 1.0 to about 0.76 at an angle of attack of 0° with the central body in the design position.

NACA RM L53G10a

INVESTIGATION OF WING FLUTTER AT TRANSONIC SPEEDS FOR SIX SYSTEMATICALLY VARIED WING PLAN FORMS. George W. Jones, Jr., and Hugh C. DuBose. August 1953. 32p. diagrs., photos., 3 tabs. (NACA RM L53G10a)

An investigation of the effects of systematic variations in wing plan form on the flutter speed at Mach numbers from 0.7 to 1.4 and at zero angle of attack has been conducted in the 26-inch Langley transonic blowdown tunnel. The angle of sweepback was varied from 0° to 60° on wings of aspect ratio 4, and the aspect ratio was varied from 2 to 6 on wings with 45° of sweepback. The results are presented as ratios between the experimental flutter speed and the reference flutter speed calculated on the basis of incompressible two-dimensional flow. This ratio, designated as the flutter-speed ratio, is plotted as a function of Mach number for the various wings.

NACA RM L53G13a

NOTES ON DAMPING IN ROLL AND LOAD DISTRIBUTIONS IN ROLL AT HIGH ANGLES OF ATTACK AND HIGH SUBSONIC SPEED. Richard E. Kuhn. August 1953. 18p. diagrs., tab. (NACA RM L53G13a)

This report presents some recent information on the damping-in-roll-derivative C_{l_p} of swept, unswept, and triangular plan forms at angles of attack up to 13° and Mach numbers up to 0.91, including some effects of fences and leading-edge notches. Some experimental information on span-load distribution of a 45° swept wing while rolling and a procedure for estimating the rolling load distribution are included.

NACA RM L53G16

EXPERIMENTAL INVESTIGATION OF AN AXIAL-FLOW SUPERSONIC COMPRESSOR HAVING ROUNDED LEADING-EDGE BLADES WITH AN 8-PERCENT MEAN THICKNESS-CHORD RATIO. Theodore J. Goldberg, Emanuel Boxer, and Peter T. Bernot. December 1953. 43p. diagrs., photos., tab. (NACA RM L53G16)

Details are presented of the results of tests in Freon-12 gas of an axial-flow supersonic compressor having rounded leading-edge blades. Tests were made for a range of tip speeds from 515 to 810 fps in Freon-12 which corresponds to a range from 1130 to 1760 fps in air. At the design tip speed of 730 fps (1600 fps in air) with guide vanes, the rotor produced a total-pressure ratio of 1.84 with an efficiency of 68 percent at an equivalent weight flow of 48.4 lb/sec of Freon-12; without guide vanes, the values were 2.06, 71.5, and 49.8, respectively.

NACA RM L53G29

A FLIGHT INVESTIGATION AT MACH NUMBERS FROM 0.67 TO 1.81 OF THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 60° DELTA-WING MISSILE CONFIGURATION HAVING AN ALL-MOVABLE TAIL. Martin T. Moul and Hal T. Baber, Jr. October 1953. 43p. diagrs., photo. (NACA RM L53G29)

A flight investigation of a 60° delta-wing missile configuration having a small 60° all-movable tail was conducted. Longitudinal stability, control, and tail hinge-moment characteristics are presented for a Mach number range of 0.67 to 1.81. Comparisons were made with the data of a delta-wing missile having half-delta wing-tip controls and with approximate theories.

NACA RM L53J09

EFFECTS OF SLOT LOCATION AND GEOMETRY ON THE FLOW IN A SQUARE TUNNEL AT TRANSONIC MACH NUMBERS. William J. Nelson and James M. Cubbage, Jr. November 1953. 46p. diagrs., photos., tab. (NACA RM L53J09)

Data from an investigation of the effects of slot location and slot geometry on the flow in a square tunnel are presented for a Mach number range up to 1.4. These data are presented as curves of center-line static-to-stagnation pressure ratio plotted as a function of the distance from the plane of the slot origin with the slots located in one, two, or four walls or in the corners of a square tunnel. Calculated static pressure and angle-of-flow distributions along the slotted boundary are presented for several slot configurations investigated in a tunnel with two opposite walls slotted. Knowledge of the static-pressure difference across the slots is shown to be inadequate to define the flow rate across the boundary. The data show that, by maintaining a given distribution of open area, slots developed in one configuration may be applied to another with but minor changes in pressure distribution.

NACA RM L53J28

AN EXPERIMENTAL INVESTIGATION OF THE TRANSONIC-FLOW-GENERATION AND SHOCK-WAVE-REFLECTION CHARACTERISTICS OF A TWO-DIMENSIONAL WIND TUNNEL WITH 24-PERCENT-OPEN, DEEP, MULTISLOTTED WALLS. Thomas B. Sellers, Don D. Davis, and George M. Stokes. December 1953. 37p. diagrs., photos. (NACA RM L53J28)

The results of tests to determine the shock-wave-reflection and flow-generation characteristics of a two-dimensional wind tunnel with 24-percent-open, deep, multislotted walls are presented. The wave-reflection tests were made at a free-stream Mach number of 1.278. Center-line Mach number distributions were determined over a Mach number range from 0.80 to 1.32 and at wall-divergence angles of $0'$, $20'$, and $40'$. The suction outflows required for flow generation were measured over the Mach number and divergence-angle range.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53K19

EFFECTS OF AUXILIARY AND EJECTOR PUMPING ON THE MACH NUMBER ATTAINABLE IN A $4\frac{1}{2}$ - BY $4\frac{1}{2}$ -INCH SLOTTED TUNNEL AT LOW PRESSURE RATIOS. John S. Dennard and Barney H. Little, Jr. January 1954. 29p. diagrs., photos. (NACA RM L53K19)

The test-section Mach number was measured as a function of total pressure, slot flow removed by an auxiliary pump, and slot flow removed using the main stream as an ejector (as controlled by a variable ejector area and slot-flow reentry flaps at the downstream end of the slots) in a 4-1/2 by 4-1/2 inch slotted tunnel at Mach numbers up to 1.2 and Reynolds numbers from 4×10^6 to 7×10^6 per foot. Without auxiliary bleed the maximum Mach number was fixed by the position of the slot-flow reentry flaps and the ejector area, because these components fixed a choking station downstream of the test section. With auxiliary bleed a constant increase in Mach number of 0.1 for each 3.5 percent of main-stream flow bled off was measured and was little affected by flap position, ejector area, and Mach number. The results of this investigation when applied to a practical problem showed that substantial power savings could be realized in a slotted tunnel by the use of auxiliary-powered slot bleed.

NACA RM L54G13

SOME EFFECTS OF AILERON SPAN, AILERON CHORD, AND WING TWIST ON ROLLING EFFECTIVENESS AS DETERMINED BY ROCKET-POWERED MODEL TESTS AND THEORETICAL ESTIMATES. H. Kurt Strass and Warren A. Tucker. September 1954. 29p. diagrs., photos., tabs. (NACA RM L54G13)

The variation of rolling effectiveness with spanwise aileron extent has been determined for full-chord ailerons, and these data have been correlated with the results of a previous investigation concerning partial-chord trailing-edge ailerons. A limited check upon the principle of aerodynamic superposition was made by comparing estimates based on these data with data from tests employing twisted wings. These results are compared with values calculated by means of linear theory.

NACA RM L54G21a

FLIGHT DETERMINATION OF THE DRAG OF CONICAL-SHOCK NOSE INLETS WITH VARIOUS COWLING SHAPES AND AXIAL POSITIONS OF THE CENTER BODY AT MACH NUMBERS FROM 0.8 TO 2.0. Charles F. Merlet and Leonard W. Putland. September 1954. 41p. diagrs., photos., tabs. (NACA RM L54G21a)

External-drag data are presented for conical-shock nose inlet models with conic, parabolic, and 1-series profiles operating at both supercritical and subcritical flow rates. The tests were made at an angle of attack of 0°, using rocket-propelled models in free flight at Mach numbers from 0.8 to 2.0, and for Reynolds numbers based on body maximum diameter from 2×10^6 to 7×10^6. At a Mach number of approximately 1.1, the external drag appeared to be independent of profile shape. As the Mach number increased, the drag coefficients of the conic cowls became progressively lower than that of either the parabolic or the 1-series. Changing the external lip angle of the conic cowls from 5° to 17° had little effect on the external drag at maximum flow rates.

NACA RM L55B03

AN INVESTIGATION OF THE EFFECTS OF RAPID SKIN HEATING ON BOX BEAMS LOADED IN BENDING. Richard A. Pride. March 1955. 24p. diagrs., photos., tabs. (NACA RM L55B03)

Two beams of each of three web types were loaded in bending and subjected to rapid skin heating at rates of about 50° F to 70° F per second. Skin buckling, which can be predicted by a simplified analysis, occurred in channel-web beams because of thermal stresses superimposed on bending stresses. Skin buckling due to thermal stresses did not occur when the supporting web structure was changed to either corrugated webs or truss webs. In spite of the large variations in skin-buckling effects, thermal stresses appeared to have little influence on failing strength.

NACA RM L55F13

TESTS OF AERODYNAMICALLY HEATED MULTIWEB WING STRUCTURES IN A FREE JET AT MACH NUMBER 2. TWO ALUMINUM-ALLOY MODELS OF 20-INCH CHORD WITH 0.064- AND 0.081-INCH-THICK SKIN. George E. Griffith, Georgene H. Miltonberger, and Richard Rosecrans. August 1955. 39p. diagrs., photos., tabs. (NACA RM L55F13)

Two multiweb wing structures (MW-2 and MW-3) were tested at a Mach number of 2 under simulated supersonic flight conditions, and temperatures and strains were measured. One model failed dynamically toward the end of its test because of the combined action of aerodynamic heating and loading. The other model, with thicker skin, survived tests up to an angle of attack of 3.5° but failed statically at 5°.

NACA RM L55G22

FLIGHT MEASUREMENTS OF THE LOADS AND MOMENTS ON AN EXTERNAL STORE MOUNTED UNDER THE WING OF A SWEPT-WING FIGHTER-TYPE AIRPLANE DURING YAWING AND ROLLING MANEUVERS. Harold A. Hamer and Thomas C. O'Bryan. September 1955. 37p. diagrs., photo., tab. (NACA RM L55G22)

Flight measurements to determine the effects of maneuvering on external-store characteristics have been obtained with the use of a 245-gallon auxiliary fuel tank mounted under the wing of a North American

DECLASSIFIED NACA RESEARCH REPORTS

F-86A airplane. The external-store normal- and side-load distributions, as well as the pylon side-load distributions, were measured during continuous sideslips, rudder kicks, and abrupt aileron rolls by means of an integrating pressure system at speeds up to the maximum Mach number obtainable and at lift coefficients up to about the airplane buffet boundary. The results are presented in the form of aerodynamic load-coefficient distributions and their corresponding overall force and moment coefficients in conjunction with a brief summary of the inertia loads experienced by the store.

NACA RM L55J13a

A METHOD FOR THE DESIGN OF POROUS-WALL WIND TUNNELS. George M. Stokes. January 1956. 50p. diagrs., photo., tabs. (NACA RM L55J13a)

This report contains a description of a general method for the design of a porous-wall wind tunnel which can be applied to the design of low-supersonic wind tunnels. This design method is concerned with the development of a uniform supersonic flow in the wind tunnel and the selection of the proper test-section open ratio necessary to give minimum shock-wave-reflection interference. The main feature of the method is its ability to indicate how design requirements and wall porosity characteristics can be combined to achieve a good flow for desired conditions. A limited amount of experimental data have been obtained to show that the method can successfully produce a suitable flow field for model testing.

NACA RM L56C07

AN EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF SEVERAL DIFFUSERS AND DIFFUSER-ENTRANCE—MIXING SECTION COMBINATIONS ON THE POWER REQUIREMENTS OF A $4\frac{1}{2}$-INCH BY $4\frac{1}{2}$-INCH SLOTTED TRANSONIC WIND TUNNEL. John S. Dennard. June 1956. 65p. diagrs., tabs. (NACA RM L56C07)

A $4\frac{1}{2}$-inch-square tunnel in which two opposite walls were slotted has been tested to determine the effects of various slot exit shapes, mixing sections, and diffusers on power requirements. Information obtained included measurements of the required overall pressure ratio to operate the tunnel, the effects of auxiliary bleed flow, diffuser static pressure ratios and distributions, and diffuser total pressure distributions. Power parameters were determined from the integrated values of the total pressures at the diffuser exit together with the auxiliary bleed-flow rate.

NACA RM L56G02

EFFECT OF A FUSELAGE ON THE LOW-SPEED LONGITUDINAL AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK WING WITH DOUBLE SLOTTED FLAPS. Rodger L. Naeseth. September 1956. 31p. diagrs., tabs. (NACA RM L56G02)

A low-speed investigation has been made to determine the effect of a fuselage on the longitudinal aerodynamic characteristics of a 45° sweptback wing equipped with 0.35-semispan double-slotted flaps. The wing had an aspect ratio of 3.7, a taper ratio of 0.41, and a streamwise thickness ratio of 0.086. The cylindrical fuselage had an ogival nose and ratio of diameter to wingspan of 0.12. The double-slotted flaps consisted of a 0.213-wing-chord main flap and either a 0.500-flap-chord vane or a 0.266-flap-chord vane. The tests, in general, were made at a Reynolds number of 1.8×10^6; however, tests for one deflection of the double-slotted flaps were made over a range of Reynolds numbers of 0.93×10^6 to 3.35×10^6. The fuselage had a favorable effect on the lift characteristics of the double-slotted flaps. However, the fuselage had an adverse effect on the lift characteristics of an extended plain flap.

NACA RM L57G02

AIRPLANE MEASUREMENTS OF ATMOSPHERIC TURBULENCE FOR ALTITUDES BETWEEN 20,000 AND 55,000 FEET OVER THE WESTERN PART OF THE UNITED STATES. Thomas L. Coleman and Emilie C. Coe. August 1957. 16p. diagrs., photo., tab. (NACA RM L57G02)

An analysis of a sample of data on atmospheric turbulence obtained from NACA VGH records taken on Lockheed U-2 airplanes during research flights covering approximately 40,000 miles for altitudes between 20,000 and 55,000 feet over the western part of the United States is presented. The results for the variation of intensity and amount of turbulence with altitude are compared with turbulence data previously obtained from similar operations over England and Western Europe and with earlier estimates of average turbulence conditions over the United States.

NACA TN 3783

HANDBOOK OF STRUCTURAL STABILITY. PART III - BUCKLING OF CURVED PLATES AND SHELLS. George Gerard and Herbert Becker, New York University. August 1957. iii, 154p. diagrs., tabs. (NACA TN 3783)

Available theories and test data on buckling of curved plates and shells are reviewed. The test data for torsion and external-pressure loadings are correlated in terms of linear buckling theories for both the elastic and inelastic ranges. The cases which exhibit a marked disagreement between linear theory and test data have been analyzed by a unified semi-empirical approach which is satisfactory for analysis and design purposes.

NACA TN 3784

HANDBOOK OF STRUCTURAL STABILITY. PART IV - FAILURE OF PLATES AND COMPOSITE ELEMENTS. George Gerard, New York University. August 1957. ii, 93p. diagrs., tabs. (NACA TN 3784)

Available theories on failure of flat plates are reviewed, and test data on the postbuckling behavior, effective width, and failure of flat and curved plates are correlated. Test data on the crippling strength of various formed and extruded shapes are reviewed, from which a generalized method of crippling analysis is formulated. This analysis is then applied to a variety of sections and materials in common use.

NACA TN 3785

HANDBOOK OF STRUCTURAL STABILITY. PART V - COMPRESSIVE STRENGTH OF FLAT STIFFENED PANELS. George Gerard, New York University. August 1957. ii, 89p. diagrs., tabs. (NACA TN 3785)

A generalized crippling analysis for short monolithic panels with formed or extruded stiffeners is presented. Methods are presented for determining if riveted panels act in a monolithic manner and for determining the strength of those which do not. The failure modes of intermediate-length and long stiffened panels are discussed and methods given for estimating column strength. Theory and test data on optimum stiffened panels are presented and the various factors of importance in box types of construction are considered.

NACA TN 3988

EXPERIMENTAL AND CALCULATED HISTORIES OF VAPORIZING FUEL DROPS. R. J. Priem, G. L. Borman, M. M. El Wakil, O. A. Uyehara, and P. S. Myers, University of Wisconsin. August 1957. 66p. diagrs. (NACA TN 3988)

The results of an experimental and theoretical investigation of the vaporization of fuel droplets in heated air under atmospheric pressure are presented. First, an experimental investigation of the temperature and mass histories of single droplets, with emphasis on small drops down to 500 microns, was made. Second, a comparison of experimental with calculated temperature and mass histories was made. Third, the time taken by a droplet vaporizing in high-temperature air to form a mixture of fuel vapor and air of combustible strength in the film of the droplet and at the self-ignition temperature is calculated. In addition, the vaporization of fuel droplets in a spray under conditions where one droplet influences another is investigated theoretically.

NACA TN 4031

STABILITY LIMITS AND BURNING VELOCITIES FOR SOME LAMINAR AND TURBULENT PROPANE AND HYDROGEN FLAMES AT REDUCED PRESSURE. Burton Fine. August 1957. 49p. diagrs., tabs. (NACA TN 4031)

The stability behavior for propane-oxygen-nitrogen, hydrogen-argon-"air," and hydrogen-helium-"air" burner flames is similar to that previously found for hydrogen-air flames. The propane-oxygen-nitrogen system shows greater reactivity based on flashback than does the hydrogen-air system, but less stability toward reduced pressures. The pressure exponent of burning velocity was nearly the same as for hydrogen-air flames. Critical boundary velocity gradients for laminar and turbulent flashback and turbulent blowoff were correlated with pressure; however, those for laminar blowoff were not. Critical flashback gradients for several fuel-oxidant systems follow the reciprocal of the adiabatic flame temperature exponentially, like a reaction rate.

NACA TN 4065

TENSILE PROPERTIES OF INCONEL X SHEET UNDER RAPID-HEATING AND CONSTANT-TEMPERATURE CONDITIONS. Ivo M. Kurg. August 1957. 20p. diagrs., tabs. (NACA TN 4065)

Results of rapid-heating tests of Inconel X sheet are presented for nominal temperature rates of 0.2° F to 100° F per second under constant tensile load conditions. Yield and rupture stresses obtained under rapid-heating conditions are compared with the results of conventional tensile stress-strain tests at elevated temperatures. A marked increase in strength is observed with increased temperature rates. A temperature-rate parameter was used to construct master curves from which stresses and temperatures for yield and rupture can be predicted under rapid-heating conditions.

NACA TN 4074

COMPRESSIVE STRESS-STRAIN PROPERTIES OF 17-7 PH AND AM 350 STAINLESS-STEEL SHEET AT ELEVATED TEMPERATURES. Bland A. Stein. August 1957. 21p. diagrs., photo., tabs. (NACA TN 4074)

Results of compressive stress-strain tests on 17-7 PH and AM 350 stainless-steel sheet in the heat-treated and in the annealed conditions are presented for temperatures up to 1,200° F. The 17-7 PH stainless steel was heat-treated to Condition TH 1,050; the AM 350, to the double-aged condition. Representative compressive stress-strain curves are given for each material at the test temperatures. From these curves significant data such as 0.2-percent-offset yield stress, Young's modulus, and secant and tangent moduli are presented.

NACA TN 4078

A DISCUSSION OF CONE AND FLAT-PLATE REYNOLDS NUMBERS FOR EQUAL RATIOS OF THE LAMINAR SHEAR TO THE SHEAR CAUSED BY SMALL VELOCITY FLUCTUATIONS IN A LAMINAR BOUNDARY LAYER. Neal Tetervin. August 1957. 25p. diagrs. (NACA TN 4078)

By use of the linear theory of boundary-layer stability and Schlichting's formula for the maximum amplification of a disturbance, an approximate relation is derived between the Reynolds number on a cone and the Reynolds number on a flat plate for equal closeness to transition. The indication is that the ratio of the cone Reynolds number for transition, based on the distance to the cone apex, to the plate Reynolds number for transition, based on the distance to the leading edge, is not in general equal to 3, as has been suggested by other investigators, but varies from 3 when transition occurs at the minimum critical Reynolds number to unity when transition occurs at a large multiple of the critical Reynolds number.

ATMOSPHERIC TURBULENCE ENCOUNTERED BY HERMES AIRCRAFT. J. R. Heath-Smith. 1957. 20p. diagrs., tabs. ARC CP 334. (Ask for N-48960*)

Acceleration records were obtained of the turbulence encountered by B. O. A. C. Hermes aircraft in 417,000 miles of operational flying on routes from London to East and West Africa. It is shown that turbulence decreases with increasing altitude. A result of the pilot's discretion in choice of altitude and course is that the gust frequency encountered during most of the cruise is about one-third of the average atmospheric gust frequency. Between 9,500 feet and 14,500 feet gusts were encountered four times as frequently over East and West African sectors as over European sectors.

FLUTTER CALCULATIONS ON A SUPERSONIC AIRCRAFT WING. Ll. T. Niblett. 1957. 16p. diagrs. ARC CP 328. (Ask for N-48962*)

Flutter calculations have been made on a straight-tapered unswept wing of low-aspect ratio both with and without wing engines to discover the stiffness necessary to avoid flutter up to a Mach number of 2 and to find whether wing engines can be used to mass balance the wing effectively. Simple arbitrary modes of flexure and torsion were assumed and calculations were made using subsonic, transonic, and supersonic derivatives. It has been found that the stiffness required to prevent flutter of the bare wing is not excessive and that wing engines have a powerful mass balancing effect if placed forward on the wing. The transonic case is the most critical, but as the transonic derivatives used were two-dimensional this conclusion must be regarded as tentative.

RESULTS OF A FLIGHT INVESTIGATION ON CLEAR AIR TURBULENCE AT LOW ALTITUDE USING A METEOR MK: 7 AIRCRAFT. R. M. Allan. 1957. 16p. diagrs., photo., tabs. ARC CP 329. (Ask for N-48964*)

Low-level runs were made over a given route at heights below 1000 ft above ground and at an airspeed of 400 knots. A distance of 6080 nautical miles was covered and the accelerations due to gusts were recorded by a continuous trace accelerometer. The results of all the runs showed that, on the average, a 1g gust or greater occurred every 7.06 minutes. Comparison with other information on this subject showed that the results from this investigation fitted in with existing data. There were considerably more positive than negative gusts, the factor being 18 at 1.2g or greater. It would appear that for the

BRITISH REPORTS

area in which the flights were made, turbulence near the ground is not isotropic. A consideration of meteorological factors showed that on this route wind is far more powerful in producing turbulence at low altitude than the effect of sun.

THEORETICAL RELATIONSHIPS BETWEEN COMBUSTION INTENSITY AND PRESSURE DROP FOR ONE-STREAM COMBUSTION CHAMBERS. D. B. Spalding. April 10, 1957. 14p. diagrs. ARC 19,181; CF 393. (Ask for N-48968*)

Theoretical combustion performance is worked out for some two-dimensional and spherical combustion chambers employing recirculation. Account is taken of the variation of temperature and composition through the chamber. The fuel and air are assumed premixed. It is shown that a high recirculation ratio brings good combustion performance but high pressure drop. These effects are calculated quantitatively. Comparison is made with results obtained by electric analog and with a theoretical model employing random turbulence. The recirculation chambers are superior to most of those tried on the analog and greatly superior to the random-turbulence model.

LOCAL COEFFICIENTS OF SKIN FRICTION AND HEAT TRANSFER FOR TURBULENT BOUNDARY LAYERS IN TWO-DIMENSIONAL DIFFUSERS. J. N. Hool, Oxford University. 1957. 12p. diagrs. ARC R & M 2986; ARC 17,079. (Ask for N-48987*)

Considers the changes of local coefficients of skin friction and heat transfer for turbulent boundary layers in two-dimensional subsonic airstreams under rising pressure gradients. Values of the local coefficients of skin friction and heat transfer are compared on the basis of Reynolds analogy, Von Kármán's improvement to Reynolds analogy, and on the basis of similar velocity and temperature boundary-layer profiles. Test on diffusers at total angles of 4° and 7° showed that local coefficients of heat transfer, based on the measured heat-transfer values, increased with increase of the stream velocity and diffuser angle relative to the local coefficients of heat transfer, based on Reynolds analogy and on Von Kármán's improvement to Reynolds analogy. Local coefficients of heat transfer calculated on an assumed similarity of velocity and temperature distributions were unsatisfactory.

Aeronautical Research Council (Gt. Brit.)
WIND-TUNNEL FLUTTER TESTS ON A DELTA WING WITH AN ALL-MOVING TIP CONTROL SURFACE. D. R. Gaukroger. 1956. 17p. diagrs., tab. ARC R & M 2978; ARC 16,595. Supersedes RAE Structures 157. (Ask for N-48988*)

Wind-tunnel tests on a half-span model delta wing, fitted with an all-moving tip control surface, are described. The model, which is flexible, has a leading-edge sweepback of 45° and the control surface, which is rigid, has an area 9.3 percent of the gross wing area. The control surface is hinged at 47.4 percent of its root chord. Provision is made for varying the circuit stiffness and the position of the center of gravity of the control surface and its pitching moment of inertia. Tests show that certain combinations of control-surface inertia and circuit stiffness produce very low flutter speeds. The effect of reducing the control-surface area by cropping the tip is examined and in general is found to be beneficial.

N-48989*

Aeronautical Research Council (Gt. Brit.)
THE AERODYNAMIC DERIVATIVES WITH RESPECT TO A RATE OF YAW FOR A DELTA WING WITH DIHEDRAL AND AT INCIDENCE AT SUPERSONIC SPEEDS. J. H. Hunter-Tod. 1957. 23p. diagrs. ARC R & M 2887. Supersedes ARC 14,338; S & C 2562; FM 1737. (Ask for N-48989*)

The assumptions of the linearized theory of flow are made throughout; only first-order terms in the rate of turn are considered. The terms dependent on the dihedral alone are continuous and decrease numerically with rising Mach number. The remaining terms are discontinuous at a Mach number at which a leading edge becomes supersonic; in particular the rolling-moment component due to incidence changes sign; the other derivatives may do likewise in certain circumstances. The approximate theory developed in the paper breaks down as a leading edge nears the Mach wave from the vertex of the wing. The yawing amplitude for which the results quoted present reasonable approximations decreases rapidly as this condition is approached; in particular the contributions of the leading-edge suction become defined.

AN INVESTIGATION OF THE HIGH ALTERNATING STRESSES IN THE BLADES OF AN AXIAL-FLOW COMPRESSOR. J. R. Forshaw. 1957. 19p. diagrs., photos., tab. ARC R & M 2988; ARC 17,132. Supersedes NGTE R.157. (Ask for N-48990*)

A vibration investigation of the first-, second-, and third-stage stator blades of an axial-flow compressor gave high values of the alternating stresses of the order of 10,000 lb/sq in. On three runs excessive values of the alternating stress of 24,000, 27,500, and 48,000 lb/sq in. were obtained, and for these and for some of the other maximums the incidence was estimated to equal the stalling incidence. There is excitation at all speeds of low orders showing dissimilar flow in different parts of the stage and this excitation increases in a critical manner at or near stalling incidence indicating a partial stall which is localized in parts of the stage. At greater incidence the flow deteriorates, the contrast between various parts of the stage is reduced, and the level of the alternating stress falls to a value slightly higher than that at incidences lower than the partial stall.

THE REFLECTION EFFECT OF FENCES AT LOW SPEEDS. J. Weber and J. A. Lawford. 1956. 14p. diagrs. ARC R & M 2977; ARC 17,060. Supersedes RAE Tech. Note Aero 2308. (Ask for N-48991*)

This note considers the effect on the flow over a swept wing of vertical plates of small height - commonly called "fences." It is shown, as might be expected, that the nature of this effect is that of a partial-reflection plate. The effect of this partial reflection on the pressure distribution over the wing on either side of the fence has been investigated theoretically and by means of pressure measurements at low speeds on an untapered 45° swept-back wing.

THEORETICAL LOAD DISTRIBUTIONS ON FIN-BODY-TAILPLANE ARRANGEMENTS IN A SIDE-WIND. J. Weber and A. C. Hawk. 1957. 58p. diagrs., tabs. ARC R & M 2992; ARC 17,413. Supersedes RAE Aero 2518. (Ask for N-48992*)

A theory has been developed for calculating the distributions of side force and lift on fin-fuselage-tailplane arrangements in a side wind but with the tail plane set at zero incidence. The analysis is limited to incompressible flow and has been further simplified by assuming that the geometrical arrangement is in each case such as to give constant induced sidewash. The results, which can be extended to other arrangements and to compressible subcritical flow, are required for stability and stressing analyses.

EFFECT OF YAW ON THE COMPRESSIBLE LAMINAR BOUNDARY LAYER. J. Tinkler. 1957. 14p. diagrs., tab. ARC R & M 3005. Supersedes ARC 17,717; FM 2269. (Ask for N-48993*)

The equations governing the laminar compressible boundary layer on a yawed body of infinite span are transformed to give three nondimensional equations defining two velocity components and the enthalpy. Assuming that the Prandtl number is unity and that there is zero heat transfer, a relation is obtained between the stream Mach number and the angle of yaw for flows which give the same boundary-layer equations. The further assumption of viscosity proportional to the absolute temperature is made and "similar" solutions are found to be given by a family of surface Mach number distributions normal to the leading edge. "Similar" solutions, obtained from a differential analyzer, are presented for a range of two controlling parameters.

MEASUREMENTS OF THE THRUST PRODUCED BY CONVERGENT-DIVERGENT NOZZLES AT PRESSURE RATIOS UP TO 20. P. F. Ashwood, G. W. Crosse, and Jean E. Goddard. 1957. 25p. diagrs. ARC CP 326. (Ask for N-48996*)

In continuation of a previous investigation, tests have been made on a series of convergent-divergent nozzles having an included divergence angle of 20° to obtain performance data at pressure ratios applicable to jet engines operating in the flight speed range $M = 2$ to $M = 3$. A new test technique has been used which, by utilizing the ejector action of the jet from the test nozzle to reduce the exit pressure, enables the range of pressure ratios obtainable across the nozzle to be extended threefold. This technique, which has proved simple to apply and control, is described in detail.

THE INFLUENCE OF PRESSURE RATIO AND DIVERGENCE ANGLE ON THE SHOCK POSITION IN TWO DIMENSIONAL, OVER-EXPANDED, CONVERGENT-DIVERGENT NOZZLES. P. F. Ashwood and G. W. Crosse. 1957. 27p. diagrs., tab. ARC CP 327. (Ask for N-48997*)

Tests have been made to determine the influence of divergence angle and applied pressure ratio on the shock position in overexpanded, Laval-type, convergent-divergent nozzles. The tests covered a range of design pressure ratios between 3.5 and 17.0 and included divergence angles of from 5° to 40°. An empirical expression has been derived which enables the limiting pressure ratio at which the nozzle just runs full to be calculated and curves are presented from which the shock position within the nozzle can be obtained. The variation with design pressure ratio of the maximum pressure ratio obtainable across the exit shock has been determined and the results compared with those predicted using a semiempirical formula derived from shock-wave boundary-layer interaction experiments. Good agreement has been obtained.

FLOW INSTABILITY OF CENTRE-BODY DIFFUSERS AT SUPERSONIC SPEEDS. D. Beastall. 1956. 12p. diagrs., photos. ARC R & M 2933; ARC 14,519; ARC 16,599. Supersedes RAE Tech. Note Aero 2128 and RAE Tech. Note Aero 2128a. (Ask for N-48999*)

This note offers explanations for certain types of flow instability which occur with center-body diffusers at supersonic speeds. These instabilities manifest themselves as oscillations of the shock pattern ahead of the diffuser and the flow through the diffuser for certain conditions of operation and are likely to affect seriously the performance. Two main types of oscillations have been distinguished: a violent oscillation which occurs when the flow through the diffuser is throttled below a certain value; and a less severe oscillation which occurs when the vortex sheet from the intersection of the shock waves ahead of the diffuser or a separated boundary layer strikes the cowl. The explanations of the oscillations are substantiated by schlieren photographs of two- and three-dimensional model diffuser tests in a wind tunnel. It seems possible, in the light of the explanation given in this note, to be able to predict the range of instability of any center-body diffuser configuration by fairly simple model tests.

PROBLEMS OF LONGITUDINAL STABILITY BELOW MINIMUM DRAG SPEED, AND THEORY OF STABILITY UNDER CONSTRAINT. S. Neumark. 1957. 37p. diagrs. ARC R & M 2983; ARC 16,825. Supersedes RAE Aero 2504. (Ask for N-50004*)

Practical difficulties in cruising below minimum drag speed have long been known but not fully explained. The reasoning proposed by Painlevé in 1910 purported that flight below minimum drag speed should be fundamentally unstable, so that any speed error would lead to a divergence. This reasoning is shown to be invalid on the ground of the general theory of dynamic stability in uncontrolled flight, Painlevé's criterion being a grossly inadequate approximation to the condition of phugoid stability. However, the criterion may be fully vindicated for the case of flight controlled by the elevator in such a way as to maintain constant height.

Aeronautical Research Council (Gt. Brit.)
PRELIMINARY REPORT ON A GUST ALLEVIATOR INVESTIGATION ON A LANCASTER AIRCRAFT. J. Zbrozek, K. W. Smith, and D. White. 1957. 42p. diagrs., photo. ARC R & M 2972; ARC 16,572. Supersedes RAE Tech. Note Aero 2244. (Ask for N-50005*)

The investigation of gust alleviator effectiveness is limited to an analysis of statistical measurements of c. g. accelerations. The measured alleviation is much smaller than was initially expected and in some cases is even negative. Theoretical analysis, supported by experiment, indicates that the loss of gust alleviator effectiveness is mainly due to the large pitching moment contributed by the ailerons. The aircraft with gust alleviator in operation suffers a considerable loss of stability and calculations show that with increasing gust length alleviator effectiveness decreases and eventually becomes negative. Airframe flexibility also has some detrimental effect. The effectiveness of the alleviator in terms of wing root bending stress alleviation is considered to be more favorable, but no experimental data are yet available.

Aeronatical Research Council (Gt. Brit.)
THE MEASUREMENT OF HIGH FREQUENCY ALTERNATING PRESSURES IN GAS TURBINES. J. R. Forshaw and H. Taylor. 1957. 14p. diagrs., photos. ARC R & M 2990; ARC 17,134. Supersedes NGTE Memo. M. 213. (Ask for N-50008*)

Capacity-type pressure elements have been developed to record the alternating pressures in the casings of gas turbines. Thin stretched diaphragms are used to obtain adequate sensitivity. The lower natural frequencies of the diaphragm assembly occur in the required frequency range but the damping introduced permits an adequate compromise to be made. Connecting passages have been almost eliminated by having the diaphragm near the gas stream. A filtered balance air supply behind the diaphragm has been incorporated to permit calibration during the investigation and part equalization of pressures across the diaphragm so that higher sensitivities can be used. Cooling arrangements have been developed for application of element to investigate the pressures in turbine casings. The alternating pressures decrease sharply with distance from the source and special arrangements will be required to record the pressures at points other than at the limits of the gas stream.

THE CALCULATION OF THE PRESSURE DISTRIBUTION OVER THE SURFACE OF TWO-DIMENSIONAL AND SWEPT WINGS WITH SYMMETRICAL AEROFOIL SECTIONS. J. Weber. 1956. 63p. diagrs., tabs. ARC R & M 2918; ARC 16,124. Supersedes RAE Aero 2497. (Ask for N-50012*)

A simple method is described for calculating the pressure distribution on the surface of a thick two-dimensional airfoil section, at any incidence, in incompressible potential flow. It is particularly suitable for practical applications, since knowledge of the section ordinates only is required. This paper gives a complete derivation of the theory including a detailed discussion of the approximations made and their effect on the accuracy of the results. The pressure distributions calculated by the present method are identical with the exact values for airfoils of elliptic cross section, and the numerical values for Joukowsky airfoils agree well with the exact solutions. Calculations for a typical practical airfoil show good agreement with the results from S. Goldstein's method. The method is extended to sheared wings of infinite span and to the center section of swept wings.

THE TIME VECTOR METHOD FOR STABILITY INVESTIGATIONS. PART I. BASIC INFORMATION. PART II. LONGITUDINAL MOTION. K. H. Doetsch. 1957. 36p. diagrs., tab. ARC R & M 2945; ARC 16,275. Supersedes RAE Aero 2495. (Ask for N-50016*)

A semigraphical method for the analysis of aircraft stability oscillations is described. It is based on the concept of rotating time vectors representing the forces and moments acting on the aircraft. Rules are developed for the application to damped and divergent oscillations. The method is iterative, simple, and rapid. It emphasizes the phase and amplitude relationship of the variables of the motion. Thus, at each step in the analysis, close correlation with the physical facts of the motion is maintained and the contribution of each force or moment can be visualized. The immediate deduction of approximation formulas and their limitations is demonstrated and the application of the method to automatic control is discussed.

R.A.E. HIGH-SPEED WIND-TUNNEL TESTS OF THE TRAILING-EDGE CONTROLS ON A DELTA WING WITH 52-DEG SWEEPBACK. K. W. Newby. 1957. 22p. diagrs., tab. ARC R & M 2999; ARC 17,428. Supersedes RAE Aero 2451.
(Ask for N-50022*)

Three plain controls were tested - an inboard control, an outboard control, and the two combined. For a trimmed C_L of 0.2 to 0.3 there is no appreciable reduction of effectiveness on any control below $M = 0.87$. For $M = 0.94$, all controls have at least 50 percent of their low-speed effectiveness in pitch and roll. At higher incidence reductions in effectiveness occur, particularly near $M = 0.87$, but are mostly associated with the effects of control deflection on tip stalling. The tests were made at $R = 1.8 \times 10^6$. The pitching-moment characteristics show that cropping the pointed wing tip alleviates the tip stalling, as expected.

THE FLUTTER PROPERTIES OF A SIMPLE AERO-ISOCLINIC WING SYSTEM. N. C. Lambourne and A. Chinneck. 1956. 16p. diagrs., photo., tabs. ARC R & M 2869. Supersedes ARC 12,900; 0.858. (Ask for N-50026*)

The work dealt with in this report is of an exploratory nature primarily intended to provide some understanding of the flutter characteristics of a Hill aero-isoclinic wing. Essentially, this is a sweptback wing elastically designed so that the lifting loads do not affect the aerodynamic incidence. Flutter critical speeds and frequencies were measured over a range of the ratio of the bending and torsion frequencies. A subsidiary part of the report deals with a method of flutter-speed calculation in which the aerodynamic terms are restricted to static derivatives only.

KINETIC TEMPERATURE OF PROPELLER BLADES IN CONDITIONS OF ICING. J. K. Hardy and C. D. Brown. 1954. 12p. diagrs. ARC R & M 2806; ARC 10,696. Supersedes RAE Mech. Eng. 2. (Ask for N-50027*)

The kinetic temperature of a section of a propeller blade has been calculated for a blade with high thermal conductivity, and also for a blade which is non-conducting. Calculations have been made for clear air, and for conditions of icing to find the extent to which kinetic heating is effective against ice.

Aeronautical Research Council (Gt. Brit.)
A METHOD OF CALCULATING THE SHORT-PERIOD LONGITUDINAL STABILITY DERIVATIVES OF A WING IN LINEARISED UNSTEADY COMPRESSIBLE FLOW. K. W. Mangler. 1957. 36p. diagrs. ARC R & M 2924; ARC 15,316. Supersedes RAE Aero 2468. (Ask for N-50028*)

A method is developed for the calculation of the pressure distribution and the aerodynamic forces and moments on a wing performing harmonic pitching and heaving oscillations. The calculation is based on the assumption of inviscid potential flow without shock waves and is restricted to small incidence, so that the linearized theory is valid. In contrast to other work in the field the theory applies to all Mach numbers. It is restricted to small values of the reduced frequency and should be valid for the usual range of short periods occurring at present in flight.

TESTS CONCERNING NOVEL DESIGNS OF BLADES FOR AXIAL COMPRESSORS. PART I. BLADES DESIGNED FOR INCREASED WORK AT ROOT AND TIP. PART II. BLADES DESIGNED TO OPERATE IN A PARABOLIC AXIAL VELOCITY DISTRIBUTION. S. J. Andrews, R. A. Jeffs, and E. L. Hartley. 1956. 22p. diagrs. ARC R & M 2929; ARC 12,623; ARC 14,671. Supersedes NGTE Memo. M.54 and NGTE R. 104. (Ask for N-50029*)

The results obtained from low-speed tests of the first set of blades show that although the boundary-layer thickness was considerably reduced, this was achieved only at the expense of 2 percent in maximum efficiency as compared with conventional blades. The drop in efficiency is attributed to the stator blade rows which stall at incidences well below the design value, but the effect is probably not uniquely associated with variable work done. The blades designed for a variable axial-velocity profile also failed to give an improved performance. The maximum efficiency was 3 percent below that of the equivalent conventional blades and the axial-velocity profile instead of remaining approximately as assumed, deteriorated still further.

Aeronautical Research Council (Gt. Brit.)
AN EXTENSION OF MULTHOPP'S METHOD OF CALCULATING THE SPANWISE LOADING OF WING-FUSELAGE COMBINATIONS. J. Weber, D. A. Kirby, and D. J. Kettle. 1956. 24p. diagrs., tab. ARC R & M 2872; ARC 14,830. Supersedes RAE Aero 2446. (Ask for N-50030*)

A simple method is described for calculating the spanwise loading over wing-fuselage combinations. It is based on Multhopp's method, which is extended here to cover wings of finite thickness, large root chords compared with the body diameter, and also

BRITISH REPORTS

swept wings. The method is restricted to wings of moderate and large aspect ratios (above about 2). The effect of different junction shapes above and below the wing in off-center positions of the wing cannot yet be calculated. The calculation can be performed in about one computer day, and comparisons with experimental results show good agreement in the symmetrical case.

Aeronautical Research Council (Gt. Brit.)
CRITERIA FOR THE PREVENTION OF FLUTTER OF TAB SYSTEMS. H. Wittmeyer and H. Templeton. 1956. 44p. diagrs., tabs. ARC R & M 2825; ARC 13,063. Supersedes RAE Structures 57. (Ask for N-50031*)

An investigation has been made into the flutter characteristics of an idealized tab system in which the three-degrees-of-freedom normal translation of the lifting surface, rotation of the control surface, and rotation of the tab are represented. Specific cases of this idealized system represent similar idealized forms of the standard trimming, spring, servo, and geared tab systems. From a consideration of the relationships existing between the systems, criteria for flutter prevention have been developed from the criteria evolved earlier for trimming tabs.

Aeronautical Research Council (Gt. Brit.)
TECHNIQUE FOR FLUTTER TESTS USING GROUND-LAUNCHED ROCKETS, WITH RESULTS FOR UNSWEPT WINGS. W. G. Molyneux, F. Ruddlesden, and P. J. Cutt. 1956. 19p. diagrs., photos., tabs. ARC R & M 2944; ARC 13,562; ARC 14,606. Supersedes RAE Structures 72 and RAE Structures 118. (Ask for N-50032*)

A technique for the investigation of wing flutter by means of ground-launched rockets is described. An important feature of the technique is that it can be used at high speeds, including the transonic range. Model wings are attached to a solid-fuel rocket which has a miniature telemetry set housed in a detachable nose fairing. A vibration pickup and break wires are fitted in the flutter model and these modulate the output of the telemetry set to transmit flutter information to a ground station. The rocket is fired over an open artillery range and its velocity-time curve is obtained by radio reflection Doppler equipment. Results are given of tests on flutter models of unswept, untapered wings at $M = 0.4$ to 1.

N-50033*

Aeronautical Research Council (Gt. Brit.)
THE R.A.E. 4-FT X 3-FT EXPERIMENTAL LOW-TURBULENCE WIND TUNNEL. PART II. MEASUREMENTS OF TURBULENCE INTENSITY AND NOISE IN THE WORKING-SECTION. H. Schuh and K. G. Winter. 1957. 19p. diagrs. ARC R & M 2905; ARC 14,164. Supersedes RAE Aero 2412. (Ask for N-50033*)

With all the screens in the tunnel, intensities of lateral components are of the same order as the longitudinal component and range from about 0.01 percent to 0.03 percent of the mean speed. Frequency analyses have shown the longitudinal components to consist of fan frequencies and a low-frequency contribution at about 5 to 10 cps. The lateral components consist almost entirely of a similar low-frequency contribution. The low level of turbulence is confined to a restricted area near the center of the tunnel with flashes of high-intensity turbulence spreading a considerable distance from the walls. Noise measurements with the hot-wire microphone in the middle of the working section showed that above a tunnel speed of 150 ft/sec the longitudinal component consisted mainly of noise. Some measurements were also made with the hot-wire microphone in the turbulent boundary layer on the walls.

SECOND HARMONIC CONTROL ON THE HELICOPTER ROTOR. W. Stewart. 1957. 15p. diagrs. ARC R & M 2997; ARC 15,407. Supersedes RAE Aero 2472. (Ask for N-50035*)

The application of second harmonic control on a helicopter rotor causes a redistribution of the loading over the disk. This can be utilized to postpone the

BRITISH REPORTS

forward speed limitations imposed by stalling of the retreating blade. This report develops the theory for second harmonic control. The resultant flapping motion and subsequent incidence distribution depend mainly on blade-inertia number. A practical check on the flapping with a full-scale rotor on a testing tower gave excellent agreement with the theory.

N-50036*

Aeronautical Research Council (Gt. Brit.)
THE SPINNING OF MODEL AIRCRAFT AND THE PREDICTION OF FULL-SCALE SPIN AND RECOVERY CHARACTERISTICS. G. E. Pringle and D. J. Harper. 1956. vii, 104p. diagrs., photos., tabs. ARC R & M 2906; ARC 15,152. Supersedes RAE Aero 2456. (Ask for N-50036*)

The report discusses some technical aspects of a long series of tests made with dynamic scale model aircraft for the purpose of studying their spinning characteristics. Data accumulated up to the end of 1947 are included and mention is made, where appropriate, of any further work done up to the end of 1949. There is some discussion of the sensitivity of the spinning model to applied forces including those that upset the spin to produce recovery and those that alternatively generate a new spin. The difference between model- and full-scale spins is analyzed with a view to correcting the model data, and some attention is given to power-on spins. A chapter is given to special aspects of the spin of tailless aircraft and another to safety devices.

THE PROBLEM OF STRUCTURAL FAILURE DUE TO JET NOISE. Alan Powell. March 29, 1955. 32p. diagrs. ARC 17,514; 0.1177. (Ask for N-50037*)

The problem is surveyed and a general approach is suggested, depending on independence of the modes of vibration. The solution to Lagrange's equation is expressed in terms of frequency spectra: the generalized force depends on the pressure spectrum and the structure of the pressure field, expressible as correlation functions, in conjunction with the form of the modes, their joint relationship being called "modal acceptance;" some simple cases are analyzed for sound waves and a plane wall and the results suggest that modes having wavelengths approximating to those of the most intense sound will have the largest excitation forces. For practical structure the frequencies for which this happens may well lie close to the natural frequencies of vibration, resulting in relatively large amplitudes of vibration. Acoustical radiation damping as well as structural damping must be assessed, and this relates the problem to that of "panting" noise from boundary layers; virtual inertia of the air may be appreciable for large modes. The effect of the resultant stresses in terms of cumulative fatigue damage is also commented upon.

THE AERODYNAMICS OF THE VERTICAL TAIL. (L'Aerodynamique de l'empennage vertical.) W. Just. May 1957. 45p. diagrs. Translation of Société Nationale de Constructions Aeronautiques du Sud-Est, Dossier Divers 294, October 1952, 41p. (Ask for N-40645*)

An estimate is given of the peculiarities of the flow about a vertical tail and several methods of calculation are discussed by which one can determine the lateral forces and the yawing moment of the vertical tail subject to interaction by the fuselage, the wing, etc. The problem of the determination of the magnitude and the geometric characteristics of the vertical tail is also treated.

CN-49504*

THE DEVELOPMENT OF A RATIONAL VAPOR-PRESSURE FORMULA. (Der Aufbau einer rationellen Dampfdruckformel.) R. Plank. June 1957. 18p. tabs. Translation from Chemie-Ingenieur-Technik, v. 22, no. 20, 1950, p. 433-436. (Ask for CN-49504*)

In the technical literature we find, for the representation of vapor-pressure curves up to the critical point, generally very different, arbitrarily chosen formulas which are frequently not easily reconcilable with the measured values. In accordance with a criterion established a long time ago, we find that the vapor-pressure curve in the neighborhood of the critical point may be represented very accurately by a simple power function. Starting from this function and adding further appropriate terms, we can develop a rational vapor-pressure formula for the entire temperature range which, in spite of its simple structure, perfectly renders the variation of experimentally determined vapor-pressure curves.

NACA RM A53H03

AN ANALYTICAL STUDY OF THE COMPARATIVE PERFORMANCE OF SIX AIR-INDUCTION SYSTEMS FOR TURBOJET-POWERED AIRPLANES DESIGNED TO OPERATE AT MACH NUMBERS UP TO 2.0. Earl C. Watson. October 1953. 46p. diagrs. (NACA RM A53H03)

A study is presented of inlet designs and aerodynamic characteristics of air-induction systems intended for operation with a turbojet engine operating with a constant-volume air-flow process. Two-dimensional inlet designs similar to those discussed in NACA RM A52C14, plus a fixed-geometry inlet with a convergent-divergent diffuser, and an additional variable-geometry inlet are considered for Mach numbers from 0.85 to 2.0 from sea level to the stratosphere. For best performance throughout this range of Mach numbers and altitudes, it was shown that the geometry of the inlet must be such as to insure a high pressure recovery, as well as to provide for a variable entrance area. The inlets are compared on the basis of a drag evaluation neglecting viscosity.

NACA RM A54J20

EFFECT OF TAPER RATIO ON LIFT, DRAG, AND PITCHING-MOMENT CHARACTERISTICS OF THIN WINGS OF ASPECT RATIO 3 WITH 53.1° SWEEPBACK OF LEADING EDGE AT SUBSONIC AND SUPERSONIC SPEEDS. Benton E. Wetzel. January 1955. 25p. diagrs., photo., tabs. (NACA RM A54J20)

The effect of taper ratio on the lift, drag, and pitching moment of thin wings of aspect ratio 3 and with 53.1° sweepback is presented. Taper ratio was varied from 0 (a triangular wing) to 0.4. Force measurements were obtained throughout an angle-of-attack range of -4° to +17° at Mach numbers of 0.6 to 0.9 and 1.2 to 1.9. Most of the tests were at Reynolds numbers of about 3 million based on the mean aerodynamic chords of the models.

NACA RM E51A02

DESIGN AND PERFORMANCE OF AN EXPERIMENTAL AXIAL-DISCHARGE MIXED-FLOW COMPRESSOR. III - OVER-ALL PERFORMANCE OF IMPELLER AND SUPERSONIC-DIFFUSER COMBINATION. Ward W. Wilcox and William H. Robbins. April 30, 1951. 26p. diagrs., photo. (NACA RM E51A02)

An axial-discharge impeller with a convergent-divergent supersonic-diffuser cascade was investigated over a range of flow conditions and equivalent tip speeds. Diffuser-inlet Mach numbers were in the low supersonic range. At no tip speed were the requirements for starting of the cascade met nor was the design value of weight flow obtained. Application of 9-percent flow bleedoff between the impeller and the diffuser was insufficient to allow starting of the diffuser. Indications are that a diffuser with an external shock configuration would perform as well as or better than the convergent-divergent type in this range of Mach numbers.

NACA RM E51C22

INVESTIGATION OF OFF-DESIGN PERFORMANCE OF SHOCK-IN-ROTOR TYPE SUPERSONIC BLADING. Robert C. Graham, John F. Klapproth, and Frank J. Barina. May 7, 1951. 25p. diagrs., photos. (NACA RM E51C22)

An analysis of the off-design performance of shock-in-rotor type supersonic blading is presented. The overall losses are assumed divided into two groups; normal-shock losses and external-wave losses. Throughout the range of relative entrance Mach numbers from 1.35 to starting, the largest losses can be attributed to the normal shock. An improvement in performance would be expected with a reduction of the normal-shock losses by the introduction of external compression waves.

NACA RM E51G18

A TWO-DIMENSIONAL CASCADE STUDY OF THE AERODYNAMIC CHARACTERISTICS OF A TURBINE-ROTOR BLADE SUITABLE FOR AIR COOLING. Henry W. Plohr and Cavour H. Hauser. September 1951. 15p. diagrs., photos. (NACA RM E51G18)

Flow conditions at the exit of a cascade of turbine-rotor blades, suitable for use in air-cooled turbines by virtue of their relatively low solidity and thick blade profiles, were experimentally determined from static-pressure measurements using the conservation of momentum principle and schlieren photographs of the flow past the blades. Supersonic velocities were obtained over the greater portion of the blade suction surface and resulted in high blade loading without an appreciable decrease in efficiency from that obtained using blades with lower velocities.

NACA RM E51H08

INVESTIGATION OF A 24-INCH SHOCK-IN-ROTOR TYPE SUPERSONIC COMPRESSOR DESIGNED FOR SIMPLE RADIAL EQUILIBRIUM BEHIND NORMAL SHOCK. Harold Lown and Melvin J. Hartmann. December 1951. 25p. diagrs., photo. (NACA RM E51H08)

A 24-inch-diameter shock-in-rotor supersonic compressor rotor designed to obtain simple radial equilibrium behind the normal shock obtained a maximum total-pressure ratio of 2.02 at an adiabatic efficiency of 0.74 and a weight flow of 61.5 pounds per second at design speed. Although this design method considerably reduced the radial forces, there was no apparent reduction in the radial redistribution of mass flow over the radial redistribution obtained in the previous investigation. This investigation indicates that the shock boundary-layer interaction pattern and associated effects have a very large effect on the radial redistribution of mass flow through the shock-in-rotor supersonic compressor rotor.

NACA RM E52A25

COLD-AIR INVESTIGATION OF A TURBINE WITH NONTWISTED ROTOR BLADES SUITABLE FOR AIR COOLING. Thomas R. Heaton, William R. Slivka, and Leonard F. Westra. March 1952. 34p. diagrs., photos. (NACA RM E52A25)

An experimental investigation of a turbine with nontwisted rotor blades suitable for air cooling was conducted; the turbine-design requirements were the same as those of the turbine of a contemporary turbojet engine. The overall performance and the flow surveys obtained at the stator and rotor exits of a scale model of this turbine in a cold-air rig are presented. A brake internal efficiency of 0.82 was obtained at the design equivalent shaft work and design equivalent tip speed. Brake internal efficiencies of the order of 0.845 occurred at stagnation-pressure ratios and equivalent tip speeds greater than design.

NACA RM E52B27

AN EXPERIMENTAL CASCADE STUDY OF THE EFFECTS OF A SOLIDITY REDUCTION ON THE TWO-DIMENSIONAL AERODYNAMIC CHARACTERISTICS OF A TURBINE-ROTOR BLADE SUITABLE FOR AIR COOLING. Henry W. Plohr and William J. Nusbaum. May 1952. 17p. diagrs., photos. (NACA RM E52B27)

Flow conditions at the exit of a cascade of turbine-rotor blades, suitable for use in air-cooled turbines by virtue of their low solidity and thick blade profiles, were experimentally determined from static-pressure measurements using the conservation-of-momentum principle and schlieren photographs. A comparison of these results with similar published cascade data on the same blade profile at a higher solidity indicated that for the low-solidity configuration reduced turning and higher blade profile losses were obtained, along with very high blade suction-surface velocities.

NACA RM E52G01

AN ANALYTICAL METHOD FOR EVALUATING FACTORS AFFECTING APPLICATION OF TRANSPIRATION COOLING TO GAS TURBINE BLADES. Jack B. Esgar. September 1952. ii, 68p. diagrs., tabs. (NACA RM E52G01)

An analytical investigation was conducted to develop a method for evaluating factors affecting the application of transpiration cooling to aircraft gas-turbine blades. Calculations were made to determine the effects of off-design flight and engine conditions on the coolant flow and coolant supply pressure requirements for blades designed for a variety of conditions. It was found that the use of orifices at the blade base for partially metering the cooling air to local positions around the blade periphery provided blades that used a minimum of coolant at off-design conditions and in addition permitted a great simplification in the blade fabrication.

#NACA RM E52H06, by Prince and Schulze

NACA RM E52H08

PERFORMANCE CHARACTERISTICS OF CANARD-TYPE MISSILE WITH VERTICALLY MOUNTED NACELLE ENGINES AT MACH NUMBERS 1.5 TO 2.0. Leonard J. Obery and Howard S. Krasnow. September 1952. 25p. diagrs. (NACA RM E52H08)

The forces, moments, and internal engine performance of a complete missile configuration were determined at Mach numbers from 1.5 to 2.0, angles of attack from 0° to 10°, and canard-control deflections from 0° to 9-1/2°. The missile had a canard-type control surface with nacelle engines mounted above and below the fuselage. The wing shock fell behind the inlets at the design Mach number of 2.0. The overall performance of the missile and the component performances are presented. Prediction of the forces by existing theory is shown to agree reasonably well with the experimental data over the Mach number and angle-of-attack range.

NACA RM E52H29

PERFORMANCE CHARACTERISTICS AT MACH NUMBERS TO 2.0 OF VARIOUS TYPES OF SIDE INLETS MOUNTED ON FUSELAGE OF PROPOSED SUPERSONIC AIRPLANE. IV - RECTANGULAR-COWL INLETS WITH TWO-DIMENSIONAL COMPRESSION RAMPS. Paul C. Simon. October 1952. 35p. diagrs., photos. (NACA RM E52H29)

Inlet flow and drag characteristics are presented for a rectangular-cowl side inlet having an external two-dimensional compression ramp and boundary-layer bleed scoop. The effects on inlet performance resulting from the installation of sweptback cowl side fairings are also included. The investigation was conducted in the 8- by 6-foot supersonic tunnel for a range of Mach number from 0 to 2.0 and fuselage angles of attack from 0° to 12°. A critical pressure recovery of 0.83 and a supersonic mass-flow spillage of 4 percent of theoretical maximum were obtained at the inlet design Mach number of 2.0. The addition of side fairings increased the critical recovery to 0.88 and reduced the spillage to zero. The rectangular inlet without fairings exhibited stable operation for the range of variables investigated. Side fairings caused inlet instability at angle of attack.

NACA RM E52J29

ANALYTICAL COMPARISON OF TURBINE-BLADE COOLING SYSTEMS DESIGNED FOR A TURBOJET ENGINE OPERATING AT SUPERSONIC SPEED AND HIGH ALTITUDE. I - LIQUID-COOLING SYSTEMS. Wilson B. Schramm, Alfred J. Nachtigall, and Vernon L. Arne. January 1953. 52p. diagrs., tabs. (NACA RM E52J29)

The operation and effectiveness of turbine-blade liquid-cooling systems as applied to high-altitude turbojet powered supersonic interceptor aircraft are evaluated analytically. The problems encountered with each of several liquid-cooling systems using water or fuel as coolants were investigated with respect to the medium to which heat is rejected. The water-cooling system appears inadequate for the interceptor mission because of its inability to reject heat to ram air at high flight Mach number and because of considerable installation complexity. A fuel-cooling system with heat rejection to the afterburner fuel appears promising because of negligible weight and performance penalties and relatively simple installation. A regenerative liquid-cooling system, which rejects heat to compressor-discharge air, can be provided for nonafterburning engines as well as for afterburning engines if suitable fluids can be found. This system provides a "package" installation entirely contained within the engine and capable of operation without external systems in the aircraft.

NACA RM E52J30

ANALYTICAL COMPARISON OF TURBINE-BLADE COOLING SYSTEMS DESIGNED FOR A TURBOJET ENGINE OPERATING AT SUPERSONIC SPEED AND HIGH ALTITUDE. II - AIR-COOLING SYSTEMS. Wilson B. Schramm, Vernon L. Arne, and Alfred J. Nachtigall. January 1953. 50p. diagrs., tabs. (NACA RM E52J30)

The operation and effectiveness of air- and liquid-cooling systems in high-altitude, supersonic, turbojet-powered interceptor aircraft were investigated. The results obtained from analysis of the air-cooling system were presented and compared with a similar study of liquid-cooling systems presented in a companion report of this analysis. Results of the analysis showed that the simple, nonrefrigerated, air-cooling system was adequate for turbine-blade cooling at flight Mach numbers to 2.5 at an altitude of 50,000 feet. Air-cooling systems with bleed aftercooling or refrigeration based on heat rejection to afterburner fuel provide a greater margin of safety than the simple system and extend operation to higher permissible flight Mach numbers. A comparison with liquid-cooling systems indicated that the fuel-cooling system using afterburner fuel is the most desirable alternate choice for supersonic application. Regenerative liquid-cooling systems and regenerative air-bleed expansion refrigeration systems are promising long-range developments that are capable of operation over the desired range of flight conditions without affecting other aircraft installations and systems.

NACA RM E52K03

PERFORMANCE OF A SWEPT LEADING EDGE ROTOR OF THE SUPERSONIC TYPE WITH MIXED FLOW. Arthur W. Goldstein and Ralph L. Schacht. January 1953. 34p. diagrs., photo., tab. (NACA RM E52K03)

An experimental investigation with Freon-12 as the working fluid was made of a 14-inch-diameter supersonic mixed-flow axial-discharge rotor of the impulse type. The whole series of tests was made twice - once with a set of guide vanes that underturned the air and gave a somewhat lower relative inlet velocity than the design value, and once with a set that gave approximately the design values for velocity and direction. At the design tip speed of 686 feet per second (equivalent value for air, 1564 ft/sec), the weight flow was about 43.5 pounds per second (equivalent air value, 23.7 lb/sec), the pressure ratio was 6.25, and the efficiency was 80.4 percent with the first set of guide vanes. With the second set the figures are 43.3 pounds per second, 6.6, and 78.0 percent. The leading edges of the blades were sufficiently swept to give subsonic velocities normal to the leading edge and in the plane of the blade surface. This permitted large variations of weight flow but did not permit shock surfaces to be formed on the leading edge. Work output was adequately equalized at the discharge end. High tip losses indicated that tip loading and axial length are critical factors. Inadequacy of the axisymmetric design system or blade-to-blade two-dimensional flow analysis is indicated.

NACA RM E53A23

INVESTIGATION OF WATER-SPRAY COOLING OF TURBINE BLADES IN A TURBOJET ENGINE. John C. Freche and William J. Stelpflug. March 1953. 45p. diagrs., photos., tab. (NACA RM E53A23)

An analytical and experimental investigation was made with a J33-A-9 engine to determine the effectiveness of spray cooling as a means of increasing thrust by permitting engine operation at inlet-gas temperatures and speeds above rated. With the assumption of adequate spray cooling at a coolant-to-gas flow ratio of 3 percent, calculations for the sea-level static condition indicated a thrust increase of 40 percent over rated thrust may be achieved by engine operation at an inlet-gas temperature of 2000° F and an overspeed of 10 percent. Of the water-injection configurations investigated experimentally, those located in the inner ring of the stator diaphragm provided the best cooling at rated engine speed.

NACA RM E53E21

MECHANICAL DESIGN ANALYSIS OF SEVERAL NONCRITICAL AIR-COOLED TURBINE DISKS AND A CORRUGATED-INSERT AIR-COOLED TURBINE ROTOR BLADE. Merland L. Moseson, Morton H. Krasner, and Robert R. Ziemer. July 1953. 49p. diagrs., photos., tabs. (NACA RM E53E21)

As a part of the NACA investigations of air-cooled turbines, a series of turbine wheel designs was made for a turbojet engine with an axial-flow compressor. These designs were made to determine the influence of air cooling on overall engine design, weight, critical-material content, and complexity as well as to provide necessary information for the construction of research model full-scale turbines. The effect of air cooling on these factors is illustrated by the five designs presented in this report, which include the principal variations in methods of cooling-air introduction and distribution. The mechanical design, construction, and stresses of the corrugated-insert air-cooled blade utilized in all the disk designs are included. The disk designs considered are both the split-type disk and the single disk with a cooling-air shroud. All parts were designed for use of noncritical materials for applications using current turbine-inlet temperature levels. Component and total turbine wheel weights are also presented. Reductions of critical-material content as compared with uncooled designs were shown to be approximately 93 percent.

NACA RM E53H27

PERFORMANCE OF A SUPERSONIC MIXED-FLOW ROTOR WITH A SWEPT LEADING EDGE AND 0.52 INLET RADIUS RATIO. Arthur W. Goldstein and Ralph L. Schacht. November 1953. 34p. diagrs., photos., tab. (NACA RM E53H27)

A 14-inch supersonic mixed-flow rotor of high specific mass flow and an inlet radius ratio of 0.52, designed for impulse operation and uniform output, was tested in Freon-12. At the design tip speed of 686 feet per second (equivalent value for air, 1480 ft/sec), the pressure ratio, adiabatic efficiency, and equivalent weight flow were, respectively, 7.2, 76.9 percent, and 63.8 pounds per second (equivalent air value, 31.5 lb/sec/sq ft frontal area). At 70 percent speed these parameters had the values 2.9, 84.0 percent, and 51.1 pounds per second, respectively. This speed gave one of the highest efficiencies for impulse operation even though the pressure variations along the casing were the greatest. Friction with the casing appeared to be a substantial factor in affecting efficiency. Other losses were approximately 13 percent of the work input and were nearly a constant percentage of the inlet relative kinetic energy.

NACA RM E53H28

PERFORMANCE CHARACTERISTICS OF A DOUBLE-CYLINDRICAL-SHROUD EJECTOR NOZZLE. Eli Reshotko. November 1953. 57p. diagrs., tab. (NACA RM E53H28)

The performance characteristics of a double-shroud ejector were investigated for the purpose of evaluating its effectiveness as an exit nozzle. Calculations based on ejector performance data, taken with the ejector discharging into quiescent air, indicate that thrust performance on the order of ideal nozzle thrust may be obtained over a Mach number range of 0.8 to 2.3 from a double-shroud ejector. Maximum thrust is obtained with maximum pressure recovery of the secondary- and tertiary-air inlets. Short secondary shrouds, high secondary weight flows, and low (not necessarily zero) tertiary weight flows are desirable. The results of a simplified theoretical analysis are in fair agreement with those experimentally obtained.

NACA RM E55F27a

PRELIMINARY INVESTIGATION OF HOLLOW-BLADED TURBINES HAVING CLOSED AND OPEN BLADE TIPS. Gordon T. Smith and Robert O. Hickel. August 1955. 18p. diagrs., photo., tab. (NACA RM E55F27a)

The effect of using closed or open rotor blade tips on the performance of a turbine having hollow rotor blades was investigated in a 4000-pound-thrust turbojet engine. The open-tip rotor blades did not reduce turbine efficiencies and may have been responsible for a small increase in turbine efficiencies over the turbine having closed-tip blades.

NACA RM E56E16

VISUALIZATION OF ROTOR TIP SECONDARY FLOWS WITH BLADE TIP AIR DISCHARGE AND SUCTION IN A LOW-SPEED TURBINE. Milton G. Kofskey and Hubert W. Allen. August 1956. 28p. diagrs., photos. (NACA RM E56E16)

Smoke was used to visualize outer-wall secondary flows in a low-speed turbine utilizing rotor tip air discharge and suction. Photographs as well as visual observations of the effect of tip air discharge and suction were made by independently varying the direction and quantity of the tip air discharge and suction, and varying tip clearance, and main-stream airspeed. In addition, the cross-sectional area of the hollow blade discharge opening was varied for the case of tip air discharge.

NACA RM L50H02

A COMPARISON OF THE AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF FOUR WING-FUSELAGE CONFIGURATIONS AS DETERMINED FROM DIFFERENT TEST TECHNIQUES. Charles J. Donlan, Boyd C. Myers, II, and Axel T. Mattson. October 4, 1950. 66p. diagrs., photos., tabs. (NACA RM L50H02)

A comparison is made of the high-speed aerodynamic characteristics of a family of four wing-fuselage configurations of 0°, 35°, 45°, and 60° sweepback as determined from transonic-bump model tests in the Langley high-speed 7- by 10-foot tunnel, sting-supported model tests in the Langley 8-foot high-speed tunnel and in the Langley high-speed 7- by 10-foot tunnel, and rocket model tests conducted by the Langley Pilotless Aircraft Research Division. A complementary study of the effect of Mach number gradients and streamline curvature on bump results is also included.

NACA RM L51H01

ANALYSIS OF LONGITUDINAL STABILITY AND TRIM OF THE BELL X-1 AIRPLANE AT A LIFT COEFFICIENT OF 0.3 TO MACH NUMBERS NEAR 1.05. Hubert M. Drake, John R. Carden, and Harry P. Clagett. October 1951. 30p. diagrs., photo., tab. (NACA RM L51H01)

An analysis has been made of the flight test data obtained with two X-1 airplanes having 10-percent-thick wings and an 8-percent-thick tail and 8-percent-thick wings and a 6-percent-thick tail. The variation with Mach number of the rate of change of downwash angle of attack, the static stability, and the airplane trim were obtained at a lift coefficient of 0.3.

NACA RM L52B08

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF THREE 4-PERCENT-THICK WINGS OF SWEEPBACK ANGLES 10.8°, 35°, AND 47°, ASPECT RATIO 3.5, AND TAPER RATIO 0.2 IN COMBINATION WITH A BODY. Ralph P. Bielat. July 1952. 33p. diagrs., photos., tab. (NACA RM L52B08)

An investigation was conducted in the Langley 8-foot transonic tunnel of the effects of sweepback angle on wing-body characteristics at Mach numbers varying from 0.50 to approximately 1.12. Sweepback angles of 10.8°, 35°, and 47°, based on the 0.25-chord line were investigated. All the wing models had 4-percent-thick sections parallel to the model plane of symmetry, an aspect ratio of 3.5, and a taper ratio of 0.2.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L52H06a

FREE-FLIGHT MEASUREMENTS OF SOME EFFECTS OF SPOILER SPAN AND PROJECTION AND WING FLEXIBILITY ON ROLLING EFFECTIVENESS AND DRAG OF PLAIN SPOILERS ON A TAPERED SWEPTBACK WING AT MACH NUMBERS BETWEEN 0.6 AND 1.6. Eugene D. Schult and E. M. Fields. October 1952. 30p. diagrs., photo., tab. (NACA RM L52H06a)

Spoiler rolling effectiveness and drag as affected by spoiler projection, spoiler span, spoiler spanwise location, and wing flexibility were measured over the Mach number range from 0.6 to 1.6 by utilizing rocket-propelled test vehicles in free flight. The test wing was swept back 45° along the quarter chord, had an aspect ratio of 4.0, taper ratio of 0.6, NACA 65A006 profiles, and solid sharp-edged spoilers located along the 70-percent-chord line. Spoiler heights of 2-percent and 5-percent chord were tested at various spanwise positions. The results showed that the full-span spoiler had the highest rolling effectiveness for a given projection of all configurations at all speeds tested and that the inboard half-span spoiler was approximately twice as effective as the outboard half-span spoiler. The outboard quarter-span spoiler was ineffective as a roll-producing device. Increasing the spoiler span gave more rolling effectiveness per unit drag than did increasing the spoiler height. Comparison of spoilers and ailerons at the same rolling effectiveness indicated that the spoiler had lower wing twisting moments but greater drag than the aileron; however, for the inboard control, the difference in drag between spoilers and ailerons became small at supersonic speeds.

NACA RM L53H14

AN ENGINEERING METHOD FOR THE DETERMINATION OF AEROELASTIC EFFECTS UPON THE ROLLING EFFECTIVENESS OF AILERONS ON SWEPT WINGS. H. Kurt Strass and Emily W. Stephens. November 1953. 82p. diagrs., tabs. (NACA RM L53H14)

A method is presented for calculating the steady-state rolling effectiveness of flexible sweptback wings at subsonic and supersonic speeds. The method is a procedure which possibly is as simple as can be devised and which, based on comparisons with experiment, still apparently is capable of providing estimates of the changes in aileron rolling effectiveness for a wide range of wing-aileron configurations within the experimental accuracy. As an aid to rapid calculation, the results of this investigation are presented in nondimensional form and have been calculated for a wide range of tapered wings varying from 0 to 1.0 in taper ratio, for wing-span—body-diameter ratios of 0, 0.2, and 0.4 and for ailerons of any spanwise extent and location. These calculations were made assuming that the wings were of homogeneous construction.

NACA RM L53H17

INVESTIGATION OF THE EFFECT OF SPANWISE POSITIONING OF A VERTICALLY SYMMETRIC OGIVE-CYLINDER NACELLE ON THE HIGH-SPEED AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK TAPERED-IN-THICKNESS WING OF ASPECT RATIO 6 WITH AND WITHOUT A FUSELAGE. H. Norman Silvers and Thomas J. King, Jr. October 1953. 62p. diagrs., tabs. (NACA RM L53H17)

Results show the effect of spanwise and vertical positioning of an ogive-cylinder nacelle on the high-speed aerodynamic characteristics of a small-size 45° sweptback wing alone and in combination with a fuselage over a Mach number range from 0.70 to 1.08. The nacelle was solid and had a fineness ratio of 9.34. Nacelle spanwise locations of 0.20, 0.46, 0.70, and 0.96 of the semispan were investigated.

NACA RM L53H18b

RELATIONSHIP OF FLOW OVER A 45° SWEPTBACK WING WITH AND WITHOUT LEADING-EDGE CHORD-EXTENSIONS TO LONGITUDINAL STABILITY CHARACTERISTICS AT MACH NUMBERS FROM 0.60 TO 1.03. F. E. West, Jr., and James H. Henderson. October 1953. 47p. diagrs., photos. (NACA RM L53H18b)

In this paper is presented a study of the effect of leading-edge chord-extensions on the flow phenomena existing over a thin 45° sweptback wing at Mach numbers from 0.60 to 1.03 and of the relationship of these flow phenomena to the longitudinal stability characteristics of the wings. The study is based on chordwise pressure distributions, tuft and ink-flow studies, shadowgraph surveys, and force data.

NACA RM L53H20

TRANSONIC FLIGHT TESTS TO DETERMINE ZERO-LIFT DRAG AND PRESSURE RECOVERY OF NACELLES LOCATED AT THE WING ROOT ON A 45° SWEPTBACK WING AND BODY CONFIGURATION. Sherwood Hoffman and Austin L. Wolff. September 1953. 31p. diagrs., photos., tabs. (NACA RM L53H20)

The zero-lift drag of a high-aspect-ratio 45° sweptback wing and body combination with nacelles having the NACA 1-50-250 nose inlet located at the wing root was determined by flight tests of rocket-propelled models from Mach number 0.8 to 1.3. The inlet pressure recovery at transonic speeds was determined from flight tests and at supersonic speeds by preflight jet tests. The results are compared with tests of nacelles located at the wing tip.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53H25

INVESTIGATION AT MACH NUMBERS OF 1.62, 1.93, AND 2.41 OF THE EFFECT OF OSCILLATION AMPLITUDE ON THE DAMPING IN PITCH OF DELTA-WING—BODY COMBINATIONS. Arthur Henderson, Jr. October 1953. 28p. diagrs., photos. (NACA RM L53H25)

Tests were made of four delta-wing and body combinations at Mach numbers of 1.62, 1.93, and 2.41 and covered a Reynolds number range of 0.44×10^6 to 1.69×10^6. The wings had 25°, 30°, 35°, and 45° semiapex angles. Results indicate that, in general, the variation of damping with amplitude is small, and that the damping may be satisfactorily approximated by theory.

NACA RM L53H26

RECENT EXPERIENCES WITH FLUTTER FAILURE OF SWEPTBACK, TAPERED WINGS HAVING OUTBOARD, PARTIAL-SPAN SPOILER CONTROLS. H. Kurt Strass and Edward T. Marley. October 1953. 20p. diagrs., photos., tabs. (NACA RM L53H26)

The Langley Pilotless Aircraft Research Division has conducted an investigation by means of rocket-propelled test vehicles in free flight to determine the nature of repeated wing failures encountered by some spoiler-equipped, flexible, sweptback, tapered wings. The results of this investigation show that the cause of the repeated failures was spoiler-induced flutter of the bending-torsion type. The portions of the telemeter records showing the onset of flutter and resulting failure of two models are presented.

NACA RM L53H27

LOW-SPEED STATIC STABILITY AND CONTROL CHARACTERISTICS OF A 1/4-SCALE MODEL OF THE BELL X-1 AIRPLANE EQUIPPED WITH A 4-PERCENT-THICK, ASPECT-RATIO-4, UNSWEPT WING. William C. Moseley, Jr., and Robert T. Taylor. November 1953. 53p. diagrs., photos., tab. (NACA RM L53H27)

This paper presents the results of an investigation to determine the low-speed static stability and control characteristics of a 1/4-scale model of the Bell X-1 airplane equipped with a thin, low-aspect-ratio wing. The tests in the Langley 300 MPH 7- by 10-foot tunnel were made at a dynamic pressure of 25.86 pounds per square foot which corresponds to a Mach number of about 0.13 and a Reynolds number of about 1.2×10^6.

NACA RM L55B18a

EFFECT OF A WING LEADING-EDGE FLAP AND CHORD-EXTENSION ON THE HIGH SUBSONIC CONTROL CHARACTERISTICS OF AN AILERON LOCATED AT TWO SPANWISE POSITIONS. Robert F. Thompson and Robert T. Taylor. May 1955. 59p. diagrs., photo., tabs. (NACA RM L55B18a)

Incremental force and moment coefficients due to aileron deflection are presented for a wind-tunnel investigation at high subsonic speeds and angles of attack up to 24° to determine the effects of a wing leading-edge modification on the control characteristics of a flap-type aileron located at two spanwise positions. The wing was modified by a leading-edge chord-extension over the outboard 35 percent of the semispan in combination with a full-span leading-edge flap deflected 6°. The wing-fuselage model tested had a wing of aspect ratio 4, taper ratio 0.3, 45° sweepback, and NACA 65A006 airfoil sections.

NACA RM L55F14

COLLECTION AND SUMMARY OF FLAP-TYPE-AILERON ROLLING-EFFECTIVENESS DATA AT ZERO LIFT AS DETERMINED BY ROCKET-POWERED MODEL TESTS AT MACH NUMBERS BETWEEN 0.6 AND 1.6. H. Kurt Strass, Emily W. Stephens, E. M. Fields, and Eugene D. Schult. September 1955. 95p. diagrs., photos., tabs. (NACA RM L55F14)

A collection and summary are presented of the wing-aileron rolling-effectiveness data which have been obtained during a general investigation of lateral control being conducted by the Langley Pilotless Aircraft Research Division. Some effects of trailing-edge angle, aileron chord ratio, spanwise extent and location of aileron, aspect ratio, wing sweepback, and wing-tail interference are presented. Rough design charts have been prepared to show some effects of aileron trailing-edge angle at two sweepback angles, aileron chord ratio, wing aspect ratio, and spanwise extent and location of aileron. Data were measured over the Mach number range from 0.6 to 1.6, and ailerons were differentially deflected 3° to 7°.

NACA RM L55H02

FREE-FLIGHT TESTS TO DETERMINE THE POWER-ON AND POWER-OFF PRESSURE DISTRIBUTION AND DRAG OF THE NACA RM-10 RESEARCH VEHICLE AT LARGE REYNOLDS NUMBERS BETWEEN MACH NUMBERS 0.8 AND 3.0. Sherwood Hoffman. September 1955. 55p. diagrs., photos., 3 tabs. (NACA RM L55H02)

The effect of a propulsive jet on the drag and pressure distribution of the NACA RM-10 missile configuration at large Reynolds numbers has been determined by flight tests between Mach numbers 0.8 and 3.0. The jet pressure ratio and exit Mach number were about 1.5 and 3.5. The transonic jet effects produced large increases in the pressures at the base and rearmost stations on the afterbody and fins. Favorable jet interference at the base reduced the

DECLASSIFIED NACA RESEARCH REPORTS

drag at supersonic speeds. The results are compared with those obtained from linearized theory and wind-tunnel tests.

NACA RM L55H04

EFFECTS OF LEADING-EDGE RADIUS ON THE LONGITUDINAL STABILITY OF TWO 45° SWEPTBACK WINGS INCORPORATING LEADING-EDGE CAMBER AS INFLUENCED BY REYNOLDS NUMBERS UP TO 8.00×10^6 AND MACH NUMBERS UP TO 0.290. Gerald V. Foster. October 1955. 44p. diagrs. (NACA RM L55H04)

This paper presents the low-speed lift and pitching-moment characteristics of two cambered 45° sweptback wings, one of aspect ratio 3, the other of aspect ratio 5, both having airfoil sections of 9-percent thickness with a modified NACA 230 mean line. The effects of camber, leading-edge radius, Reynolds number, and Mach number on the longitudinal stability characteristics are indicated.

NACA RM L55H05a

EXPERIMENTAL STUDY OF A METHOD OF DESIGNING THE SWEPTBACK-WING—FUSELAGE JUNCTURE TO REDUCE THE DRAG AT MODERATE SUPERSONIC SPEEDS. Robert R. Howell. January 1956. 20p. diagrs., photos., tabs. (NACA RM L55H05a)

A wind-tunnel investigation has been made of the drag reductions attainable in the Mach number range between 0.81 and 1.42 by contouring the sides of the fuselage to conform to the streamline shape over a sweptback wing of infinite span. The drag of the sweptback-wing—body configuration whose body was axisymmetrically indented according to the supersonic area rule for a design Mach number of 1.2 was reduced in the Mach number range between about 1.2 and 1.4 when the fuselage side was contoured in this manner. A comparison of the variation of drag coefficient with Mach number for configurations having the fuselage axisymmetrically indented in accordance with the supersonic and transonic area rules showed no large differences in drag coefficient except at Mach numbers greater than 1.25 where the body indented according to the transonic area rule had the higher drag.

NACA RM L55H19

A SYSTEMATIC STUDY OF THE EFFECTS OF LEADING-EDGE CHORD-EXTENSIONS ON THE LOW-SPEED LONGITUDINAL STABILITY CHARACTERISTICS OF THREE 45° SWEPTBACK WINGS. H. Neale Kelly. October 1955. 113p. diagrs., photo., tabs. (NACA RM L55H19)

The results of tests to determine the influence of chord-extension geometry on the effectiveness of leading-edge chord-extensions are presented. The tests were conducted in the Langley 19-foot pressure tunnel at a Reynolds number of 4.6×10^6 and a corresponding Mach number of 0.11 on three 45° sweptback wings of aspect ratio 5 and taper ratio 0.28 designed to exhibit different types of flow separation.

NACA RM L55H24

STATISTICAL MEASUREMENTS OF LANDING CONTACT CONDITIONS OF THE BOEING B-47 AIRPLANE. Joseph J. Kolnick and Garland J. Morris. October 1955. 11p. diagrs., tabs. (NACA RM L55H24)

The landing contact conditions of the Boeing B-47 airplane were determined from photographs taken with a specially built motion-picture camera of 222 landings during daytime operations at Barksdale Air Force Base, La. From these photographs, sinking speeds and horizontal speeds were evaluated and a statistical analysis of the results was made.

NACA RM L55H26

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF INCIDENCE AND BODY INDENTATION ON THE WING LOADS OF A 45° SWEPTBACK WING-BODY COMBINATION. Robert J. Platt, Jr. January 1956. 24p. diagrs., photos., tab. (NACA RM L55H26)

The effects of an angle of incidence of 4° and body indentation on the wing loads of a sweptback wing-body combination have been investigated at Mach numbers from 0.6 to 1.2. The wing had an aspect ratio of 4, taper ratio of 0.3, sweepback of 45°, and NACA 65A006 airfoil sections parallel to the plane of symmetry. The effects of incidence were found to be nearly independent of Mach number and normal-force coefficient below the beginning of separation.

NACA RM L55H31

A THEORETICAL ANALYSIS OF A SIMPLE AERODYNAMIC DEVICE TO IMPROVE THE LONGITUDINAL DAMPING OF A CRUCIFORM MISSILE CONFIGURATION AT SUPERSONIC SPEEDS. James E. Clements. October 1955. 36p. diagrs., tab. (NACA RM L55H31)

A theoretical investigation is presented of the longitudinal dynamic characteristics of a supersonic missile configuration with additional pitch damping obtained from viscously restrained free-floating control surfaces. Variations in the floating-control hinge-moment characteristics with Mach number and altitude are considered. A substantial increase in airframe damping was obtained through a proper choice of the hinge-moment coefficients and viscous damping rate.

Reclassification Notice

NO. 120 **OCTOBER 3, 1957**

SPECIAL NOTICE

The NACA automatically receives documents, as they are issued, from many sources. The number of copies sent us varies.

In order that each NACA Laboratory may have a retention copy of current aeronautical research reports, we are asking each United States organization now sending reports to NACA on automatic distribution to increase NACA's allotment to five (5) copies. Please do not add NACA to mailing lists other than those we are on now, except at our specific request.

We ask that readers of the NACA Research Abstracts call this Special Notice to the attention of the office that controls report distribution in their own organization. If correspondence concerning this request is necessary, please direct it to:

Washington 25, D. C.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1287

SPARK IGNITION OF FLOWING GASES. Clyde C. Swett, Jr. 1956. ii, 18p. diagrs., tabs. (NACA Rept. 1287)

Research conducted at the NACA Lewis laboratory on ignition of flowing gases by means of long-duration discharges is summarized and analyzed. Data showing the effect of a flowing combustible mixture on the physical and electrical characteristics of spark discharges and data showing the effects of variables on the spark energy required for ignition of the combustible mixture are presented. A theory of ignition that has been developed to predict the effect of many of the gas-stream and spark variables is described and applied to a limited amount of experimental data. The trends observed for ignition in flowing gases were similar to those observed in quiescent gases with the exception that increasing velocity and turbulence increased the ignition energy requirements. Lengthening of the discharge path by the flowing stream results in less energy being available to the important part of the discharge length. Flow also causes multiple discharges which should be avoided since they represent an energy loss. Less energy is required for ignition with an "arc" discharge than with a "glow" discharge. Effects of most of the variables on ignition energy requirements were predicted by theoretical equations; the effects of fuel-air ratio, however, required an empirical correction to the equations.

NACA Rept. 1289

CONTRIBUTIONS ON THE MECHANICS OF BOUNDARY-LAYER TRANSITION. G. B. Schubauer and P. S. Klebanoff, National Bureau of Standards. 1956. ii, 11p. diagrs. (NACA Rept. 1289. Supersedes TN 3489)

The manner in which flow in a boundary layer becomes turbulent was investigated on a flat plate at wind speeds generally below 100 feet per second. Hot-wire techniques were used, and many of the results are derived from oscillograms of velocity fluctuations in the transition region. The more familiar aspects of transition are discussed, and the facts discovered while studying the characteristics of artificially produced turbulent spots are presented.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1303

WIND-TUNNEL INVESTIGATION OF A NUMBER OF TOTAL-PRESSURE TUBES AT HIGH ANGLES OF ATTACK. SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS. William Gracey. 1957. ii, 10p. diagrs., tab. (NACA Rept. 1303. Supersedes TN 3641)

The total-pressure errors of 54 total-pressure tubes at angles of attack up to 60° and Mach numbers from 0.26 to 1.62 are presented. The configurations of the various tubes differed as regards external shape, internal shape, and type of total-pressure entry. External shapes tested included cylindrical, conical, and ogival nose sections. Internal shapes and total-pressure entries were varied on the basis of such factors as size of impact openings, internal chamber shape, leading-edge slant profile, and shielding (combined with venting). The effect of these variables on the sensitivities of the tubes to angle of attack is presented.

NACA TM 1408

THE PRINCIPLES OF TURBULENT HEAT TRANSFER. (Die Grundlagen des Turbulenten Wärmeüberganges.) H. Reichardt. September 1957. 45p. diagrs., tabs. (NACA TM 1408. Translation from Archiv für die gesamte Wärmetechnik, no. 6/7, 1951, p. 129-142)

Relations are derived for calculating heat-transfer coefficients for turbulent and laminar fully developed flow and heat transfer in pipes and channels at constant wall temperature. Nusselt numbers for a round pipe are computed for Prandtl numbers from 0 to 1000 at a Reynolds number of 30,000. The eddy diffusivity of momentum is assumed to vary in a continuous manner from the wall to the center of the channel. For very high Prandtl numbers it is postulated that the eddy diffusivity of momentum varies with the fifth power of the distance from the wall when very close to the wall.

NACA TM 1411

STUDY OF THE MICRO-NONUNIFORMITY OF THE PLASTIC DEFORMATION OF STEEL. (Issledovanie mikroneodnorodnosti plasticheskoi deformatsii stali.) B. B. Chechulin. August 1957. 21p. diagrs., tab. (NACA TM 1411. Translation from Fizika Metallov i Metallovedenie, v. 1, no. 2, 1955, p. 251-260.)

In 1949 Pashkov showed experimentally the enormous variation in strain from point to point in a polycrystalline metal. These large deviations from the mean strain are believed to have important effects upon the strength and flow characteristics of a metal. This work is continued in the present paper, in which the author presents a new statistical method for the study of nonuniform strains. By means of frequency diagrams of the axial inequality of the grains of a polycrystalline metal before and after loading, the average deviation of the strain from the mean can be determined. By this method it is shown that steel with an austenitic structure undergoes strains which differ much less from the mean than steels with ferritic or pearlitic structure. In the latter case, the deviations from the mean increase continuously with the mean strain.

NACA TM 1412

AERODYNAMIC FORCES ON A VIBRATING UNSTAGGERED CASCADE. (Luftkräfte an einem schwingenden Gitter.) H. Söhngen. August 1957. 16p. diagrs. (NACA TM 1412. Translation from Zeitschrift für angewandte Mathematik und Mechanik, v. 35, no. 3, Mar. 1955, p. 81-88.)

The unsteady aerodynamic forces, based on two-dimensional incompressible flow considerations, are determined for an unstaggered cascade, the blades of which are assumed to vibrate in phase with one another in an approach flow parallel to the blades.

NACA TN 3585

DETERMINATION OF SURGE AND STALL LIMITS OF AN AXIAL-FLOW TURBOJET ENGINE FOR CONTROL APPLICATIONS. Ross D. Schmidt, George Vasu, and Edward W. McGraw. September 1957. 29p. diagrs., tab. (NACA TN 3585. Supersedes RM E53B10)

Limitations on the transient operation were determined in relation to altitude and exhaust-nozzle-area parameters. The data presented are the result of an analysis of oscillograph traces obtained when the engine was operated off steady state by introducing either a step increase or a ramp increase in fuel flow. For a given speed, a lower fuel flow was required for the engine to recover from surge or stall than was necessary for surge or stall to occur. Very little difference existed between the surge line (compressor pressure ratio against engine rotational speed) obtained under transient conditions and that obtained under steady-state conditions by decreasing the flow area with an adjustable first-stage turbine stator.

NACA TN 3989

STRENGTH AND DUCTILITY OF BAINITIC STEELS. Donald H. Desy, J. O. Brittain, and M. Gensamer, Columbia University. August 1957. 32p. diagrs., photos., tabs. (NACA TN 3989)

Some of the factors believed to affect the strength and ductile-to-brittle transition temperature of bainitic steels, including mean ferrite path and degree of internal strain, have been studied. Seven laboratory heats of carbon-molybdenum and two heats of carbon steel were transformed isothermally to bainite at various temperatures and tested. Mean-ferrite-path measurements were made on electron micrographs of three of these steels. The transition temperatures of the bainite fell between -80° and -160° C and did not vary regularly with hardness, carbon or alloy content, or mean ferrite path.

NACA TN 3990

EFFECT OF CRYSTAL ORIENTATION ON FATIGUE-CRACK INITIATION IN POLYCRYSTALLINE ALUMINUM ALLOYS. J. G. Weinberg and J. A. Bennett, National Bureau of Standards. August 1957. 22p. diagrs., photos., tabs. (NACA TN 3990)

Tests on large-grained specimens of 1100 and 5052 aluminum alloys indicate that fatigue cracks initiate in preexisting slipbands on planes that are parallel to (111) planes. Bending and torsional fatigue tests were conducted to determine which factors influence the initiation of cracks. In bending fatigue it appears that grain size and shape as well as resolved shear stress were influential, while in torsional fatigue the resolved shear stress appeared to be the only important factor.

NACA TN 3995

AN INVESTIGATION OF FLOW IN CIRCULAR AND ANNULAR 90° BENDS WITH A TRANSITION IN CROSS SECTION. Stafford W. Wilbur. August 1957. 32p. diagrs., photos., tabs. (NACA TN 3995)

An investigation at low speed was conducted to determine the relative performances of circular and annular 90° bends with various combinations of transition in cross section (circular to annular and annular to circular). Included are the exit velocity profiles, the relative total-pressure-loss coefficients measured at the exit station, and an index for the exit total-pressure distortion. Separation of the flow in the bend occurred for all configurations except those with a contracting area. With the transition in cross section downstream of the bend proper, the separated region was removed by natural mixing but was accompanied by high losses. Certain locations of the transition produced higher performances than others.

NACA TN 4013

LOW-SPEED EXPERIMENTAL INVESTIGATION OF THE MAGNUS EFFECT ON VARIOUS SECTIONS OF A BODY OF REVOLUTION WITH AND WITHOUT A PROPELLER. M. J. Queijo and Herman S. Fletcher. August 1957. 68p. diagrs., photos., tab. (NACA TN 4013)

An experimental investigation has been made at low speed to determine the Magnus effect on various sections of a body of revolution of which several sections could be rotated either as individual units or in combinations. The investigation included the measurement of the Magnus effect on the body alone and also on the body with a three-blade propeller. The tests were made over an angle-of-sideslip range from -5° to 30°, and at rotational speeds from 0 to 8,000 rpm with the propeller off and from 0 to 5,000 rpm with the propeller on.

NACA TN 4032

REDUCTION OF OXIDIZED NICHROME V POWDERS AND SINTERING OF NICHROME V BODIES. Paul Sikora and Philip Clarkin. September 1957. 18p. photos., tabs. (NACA TN 4032)

Methods of obtaining essentially oxide-free powders were evaluated by oxygen analyses, tensile tests, and microstructures of specimens made from reduced powders. The three techniques that effectively lowered the oxygen content of as-received powders at 1800° to 2150° F in a hydrogen atmosphere were (1) tumbling the powder in a rotary furnace, (2) heating with sodium hydride, and (3) heating with carbon. Microstructures and tensile properties of several specimens made from reduced powder by pressing, sintering, and hot-swaging were nearly equivalent to those of wrought material. No consistent correlation existed between tensile properties and residual-oxygen content.

NACA TN 4037

STABILITY OF LAMINAR BOUNDARY LAYER NEAR A STAGNATION POINT OVER AN IMPERMEABLE WALL AND A WALL COOLED BY NORMAL FLUID INJECTION. Morris Morduchow, Richard G. Grape, and Richard P. Shaw, Polytechnic Institute of Brooklyn. August 1957. 56p. diagrs., tabs. (NACA TN 4037)

Minimum critical Reynolds numbers for laminar instability of two-dimensional stagnation flows over a wall cooled by normal fluid injection are determined theoretically. The individual as well as the net effects of wall temperature and normal fluid injection are investigated including the special case of zero injection rate. Comparison is made with results for flow over a flat plate.

NACA TN 4039

INVESTIGATION OF THE EFFECTS OF PROFILE SHAPE ON THE AERODYNAMIC AND STRUCTURAL CHARACTERISTICS OF THIN, TWO-DIMENSIONAL AIRFOILS AT SUPERSONIC SPEEDS. Elliott D. Katzen, Donald M. Kuehn, and William A. Hill, Jr. September 1957. 59p. diagrs., tabs. (NACA TN 4039. Supersedes RM A54B08a)

The effects of thickness, trailing-edge bluntness, boattailing, and forward profile were determined. The results indicated that available theoretical methods were adequate for calculating the lift and pitching moment of the airfoils under all conditions of the test. The theoretical methods for calculating forebase drag and correlation curves for estimating base pressure were adequate for predicting the total drag when the position of transition was known.

NACA TN 4063

EQUATIONS, TABLES, AND FIGURES FOR USE IN THE ANALYSIS OF HELIUM FLOW AT SUPERSONIC AND HYPERSONIC SPEEDS. James N. Mueller. September 1957. 178p. diagrs., tab. (NACA TN 4063)

This report presents equations, tables, and figures for use in the analysis of helium (specific-heat ratio of 5/3) flow at supersonic and hypersonic speeds (Mach numbers 1 to 40). The equations provide the perfect-gas relations for continuous one-dimensional flow, normal- and oblique-shock waves, and Prandtl-Meyer expansions. The tables present useful dimensionless ratios for continuous one-dimensional flow and for normal-shock waves as functions of Mach number. Figures of the helium viscosity relation as a function of temperature, mass-flow rates as a function of Mach number and temperature, the Reynolds number as a function of Mach number and stagnation temperature, and the oblique-shock characteristics of wedges and cones at Mach numbers of 12, 16, 20, and 24 are shown.

NACA TN 4066

A METHOD UTILIZING DATA ON THE SPIRAL, ROLL-SUBSIDENCE, AND DUTCH ROLL MODES FOR DETERMINING LATERAL STABILITY DERIVATIVES FROM FLIGHT MEASUREMENTS. Bernard B. Klawans and Jack A. White. August 1957. 38p. diagrs., tabs. (NACA TN 4066)

A method for determining lateral stability derivatives from flight measurements is obtained by arranging the lateral equations of motion in such form that information from each of the three modes of lateral motion may be utilized.

NACA TN 4071

A CORRELATION OF RESULTS OF A FLIGHT INVESTIGATION WITH RESULTS OF AN ANALYTICAL STUDY OF EFFECTS OF WING FLEXIBILITY ON WING STRAINS DUE TO GUSTS. C. C. Shufflebarger, Chester B. Payne, and George L. Cahen. August 1957. 40p. diagrs., tab. (NACA TN 4071)

An analytical study of the effects of wing flexibility on wing strains due to gusts has been made for four spanwise stations of a four-engine bomber airplane, and the results have been correlated with results of a previous flight investigation. The measured bending-strain amplification factors due to wing flexibility (ratio of strain for the flexible airplane to strain for the "rigid" airplane) at a station near the wing root were 1.09 when based on the ratio of root-mean-square values and approximately 1.19 when based on the ratio of strains obtained from distributions of strain peaks. The amplification factors decreased with each successive outboard station and then increased slightly at the tip station. When the airplane was considered to have three degrees of freedom (vertical motion and wing bending in the first and second symmetric bending modes), calculated amplification factors were in reasonable agreement with the measured results.

NACA TN 4075

TENSILE STRESS-STRAIN PROPERTIES OF 17-7 PH AND AM 350 STAINLESS-STEEL SHEET AT ELEVATED TEMPERATURES. Ivo M. Kurg. September 1957. 16p. diagrs., tabs. (NACA TN 4075)

Tensile stress-strain test results for 17-7 PH and AM 350 stainless-steel sheet are presented for temperatures from room temperature to 1,300° F. Stress-strain curves and data for yield and ultimate stresses, Young's modulus, and elongation are given in tabular and graphical form. A comparison is made between the tensile and compressive properties.

NACA TN 4076

CALCULATED AND MEASURED STRESSES IN SIMPLE PANELS SUBJECT TO INTENSE RANDOM ACOUSTIC LOADING INCLUDING THE NEAR NOISE FIELD OF A TURBOJET ENGINE. Leslie W. Lassiter and Robert W. Hess. September 1957. 33p. diagrs. (NACA TN 4076)

Flat 2024-T3 aluminum panels measuring 11 inches by 13 inches were tested in the near noise fields of a 4-inch air jet and turbojet engine. The stresses which were developed in the panels are compared with those calculated by generalized harmonic analysis. The calculated and measured stresses were found to be in good agreement. In order to make the stress calculations, supplementary data relating to the transfer characteristics, damping, and static response of flat and curved panels under periodic loading are necessary and were determined experimentally. In addition, an appendix containing detailed data on the near pressure field of the turbojet engine is included.

NACA TN 4077

STATIC LONGITUDINAL AND LATERAL STABILITY CHARACTERISTICS AT LOW SPEED OF 45° SWEPTBACK-MIDWING MODELS HAVING WINGS WITH AN ASPECT RATIO OF 2, 4, OR 6. David F. Thomas, Jr., and Walter D. Wolhart. September 1957. 30p. diagrs., photos., tabs. (NACA TN 4077)

Results are presented of tests conducted in the Langley stability tunnel to determine the effects of various components and combinations of components on the static longitudinal and lateral stability characteristics at low speed of a series of 45° sweptback-midwing-airplane configurations having wings with an aspect ratio of 2, 4, or 6. The tests were made at a dynamic pressure of 24.9 pounds per square foot which corresponds to a Mach number of 0.13 and Reynolds numbers of 1.00×10^6, 0.71×10^6, and 0.58×10^6 based on the respective wing mean aerodynamic chords. The angle-of-attack range covered was from -4° to 32° and the sideslip angles used for the lateral-derivative tests were 5° and -5°. An increasing loss in tail contribution to directional stability both with increasing wing aspect ratio and increasing angle of attack was found to be a principal cause of all the complete models becoming directionally unstable in the high angle-of-attack range.

CURRENT NACA RESEARCH REPORTS

NACA TN 4079

WIND-TUNNEL INVESTIGATION OF EXTERNAL-FLOW JET-AUGMENTED DOUBLE SLOTTED FLAPS ON A RECTANGULAR WING AT AN ANGLE OF ATTACK OF 0° TO HIGH MOMENTUM COEFFICIENTS. Edwin E. Davenport. September 1957. 31p. diagrs., tabs. (NACA TN 4079)

A wind-tunnel investigation has been made to determine the characteristics of external-flow jet-augmented double slotted flaps which appear suitable for application to airplanes with pod-mounted engines. The investigation included tests of a rectangular wing with an aspect ratio of 6 over a momentum-coefficient range from 0 to 28. Lift coefficients larger than the jet reaction in the lift direction were obtained with the external-flow jet-augmented double slotted flaps.

NACA TN 4088

PRACTICAL SOLUTION OF PLASTIC DEFORMATION PROBLEMS IN ELASTIC-PLASTIC RANGE. A. Mendelson and S. S. Manson. September 1957. 52p. diagrs., tab. (NACA TN 4088)

A practical method for solving plastic deformation problems in the elastic-plastic range is presented. The method is one of successive approximations and is illustrated by four examples which include a flat plate with temperature distribution across the width, a thin shell with axial temperature distribution, a solid cylinder with radial temperature distribution, and a rotating disk with radial temperature distribution.

NACA TN 4089

THE MECHANISM OF THERMAL-GRADIENT MASS TRANSFER IN THE SODIUM HYDROXIDE - NICKEL SYSTEM. Charles E. May. September 1957. 54p. diagrs., tabs. (NACA TN 4089)

"Thermal-gradient mass transfer" was investigated in the molten sodium hydroxide - nickel system. Kinetic equations are theoretically derived. Possible mechanisms (physical, electrochemical, and chemical) are discussed. The following mechanism is found to be most probable:

$$Na_2NiO_2 + 2Na \underset{\text{Hot zone}}{\overset{\text{Cold zone}}{\rightleftharpoons}} 2Na_2O + Ni$$

This mechanism requires that the chemical reaction is the rate-determining step in dynamic systems and that the diffusion process is the rate-controlling step in static systems. Beneficial and detrimental effects of additives are interpreted in terms of the probable mechanism.

NACA TN 4090

ANALYSIS OF SHOCK MOTION IN DUCTS DURING DISTURBANCES IN DOWNSTREAM PRESSURE. Herbert G. Hurrell. September 1957. 11p. diagr. (NACA TN 4090)

A linearized analysis is made of the effect of small downstream pressure disturbances on the position of a normal shock in a duct with area variation. In the analysis, the gas flow is treated as quasi-one-dimensional and nonviscous. The analysis shows that, within a given frequency limit, shock position is related to small disturbances in downstream pressure by a first-order lag. The time constant and the gain of the lag are expressed in terms of a dimensionless time constant that depends only on the steady-state Mach number of the shock.

NACA TN 4103

IMPACT-LOADS INVESTIGATION OF CHINE-IMMERSED MODEL HAVING A CIRCULAR-ARC TRANSVERSE SHAPE. Philip M. Edge, Jr. September 1957. 35p. diagrs., photo., tab. (NACA TN 4103)

Hydrodynamic-impact-loads data were obtained at the Langley impact basin from tests of a narrow-beam model having a circular-arc transverse shape of 1-beam radius. Tests were run in smooth water at fixed trims over a range of landing conditions for a beam-loading coefficient of 18.59 with a few runs for beam-loading coefficients of 27.59 and 36.57. The data are compared with loads predicted by theory and with experimental loads obtained from similar tests with a concave-convex transversely curved shape.

NACA TN 4104

THE USE OF PURE TWIST FOR DRAG REDUCTION ON ARROW WINGS WITH SUBSONIC LEADING EDGES. Frederick C. Grant. August 1957. 28p. diagrs., tabs. (NACA TN 4104)

Linearized-theory calculations are presented for the drag reduction achieved by applying the first three terms of a power series for twist to flat delta wings and by applying linear twist to flat arrow wings with sonic trailing edges. Tip and root incidence angles for the optimum linearly twisted wings are shown. The calculations cover the speed range of subsonic leading edges.

CURRENT NACA RESEARCH REPORTS

NACA TN 4106

IMPACT-LOADS INVESTIGATION OF A CHINE-IMMERSED MODEL HAVING A LONGITUDINALLY CURVED BOW AND A V-BOTTOM WITH A DEAD-RISE ANGLE OF 30°. Philip M. Edge, Jr., and John S. Mixson. September 1957. 24p. diagrs., photo., tabs. (NACA TN 4106)

Hydrodynamic-impact-loads data were obtained at the Langley impact basin with a chine-immersed model having a dead-rise angle of 30° and the forward half longitudinally curved upward on a radius of 10 beams. Impacts were made at fixed trim in smooth water at a beam-loading coefficient of 18.8 and over a range of landing-approach conditions. The data are evaluated as to the extent of bow immersion, and the maximum loads obtained are compared with loads predicted by theory for a straight-keel model.

NACA TN 4107

EFFECTS OF AIRPLANE FLEXIBILITY ON WING STRAINS IN ROUGH AIR AT 5,000 FEET AS DETERMINED BY FLIGHT TESTS OF A LARGE SWEPT-WING AIRPLANE. Richard H. Rhyne and Harold N. Murrow. September 1957. 32p. diagrs., photo., tabs. (NACA TN 4107)

The results of a flight investigation on a large swept-wing bomber airplane to determine the overall magnitude of the aeroelastic effects on the bending and shear strains in rough air show that the amplification of strain per unit acceleration in gusts, as compared with strain per unit acceleration for a "rigid" and "quasi-rigid" reference, increases with outboard spanwise station to a maximum amplification factor of 2.72.

NACA TN 4108

A THERMAL SYSTEM FOR CONTINUOUS MONITORING OF LAMINAR AND TURBULENT BOUNDARY-LAYER FLOWS DURING ROUTINE FLIGHT. Norman R. Richardson and Elmer A. Horton. September 1957. 25p. diagrs., photos. (NACA TN 4108)

A thermal system has been developed which could be used to determine whether the boundary layer on a wing in flight is turbulent or laminar. Detectors cemented to the wing surface combine the functions of heating and temperature measurement. Detection is based on the difference in rate of heat transfer to a turbulent boundary layer as compared with that to a laminar boundary layer. Tests in the Langley low-turbulence pressure tunnel indicate that a usable signal is obtained when the Reynolds number per foot is about 0.15×10^6 or greater. This system, when used with a recording galvanometer and a motor-driven selector switch, would permit continuous and unattended monitoring of the boundary layer during routine flight.

NACA TN 4119

WIND-TUNNEL INVESTIGATION OF EFFECTS OF GROUND PROXIMITY AND OF SPLIT FLAPS ON THE LATERAL STABILITY DERIVATIVES OF A 60° DELTA-WING MODEL OSCILLATING IN YAW. Byron M. Jaquet. September 1957. 32p. diagrs. photos., tab. (NACA TN 4119)

An investigation was made in the Langley stability tunnel to determine the effects of the proximity of the ground and of split flaps on the lateral stability derivatives of a 60° delta-wing model oscillating continuously in yaw. The model was tested with and without the vertical tail and the split flaps, without ground, and at ground-to-model distances from 0.30 to 1.25 wing mean aerodynamic chord at angles of attack to 30°. The test Mach number was 0.13 and the Reynolds number based on the wing mean aerodynamic chord was 1.6×10^6.

UNPUBLISHED PAPERS

N-54676*

EFFECT OF LATERAL WIND ON THE BOUNDARY LAYER OF A HIGH-SPEED COMPRESSIBLE FLOW ABOUT A CYLINDRICAL OBSTACLE (WING AT AN ANGLE OR WITH SWEEPBACK). (Influenza di un vento laterale sullo strato limite di corrente compressibile ad alta velocita che investe un ostacolo cilindrico)(ala in deriva o a freccia.) Aldo Castagno. 21p. diagrs. Translation from Aerotecnica, v. 36, no. 3, July 1956, p. 152-159. (Ask for N-54676*)

A study is made of the laminar boundary layer on a cylindrical obstacle in a compressible oblique flow under the assumptions of zero heat transfer at the wall and Prandtl number equal to unity. Formulas are given which permit the computation of the distributions of the velocities and forces in the cases of the flat plate and the general wing airfoil with possible point of separation.

NACA RM A9I27

AERODYNAMIC STUDY OF A WING-FUSELAGE COMBINATION EMPLOYING A WING SWEPT BACK 63°. - EFFECTS AT SUBSONIC SPEEDS OF A CONSTANT-CHORD ELEVON ON A WING CAMBERED AND TWISTED FOR A UNIFORM LOAD AT A LIFT COEFFICIENT OF 0.25. J. Lloyd Jones and Fred A. Demele. December 5, 1949. 44p. diagrs., photos., tab. (NACA RM A9I27)

Longitudinal aerodynamic characteristics and lateral control data are presented of a cambered and twisted wing having a leading edge swept back 63° in combination with a slender fuselage and equipped with constant-chord elevons. The tests were conducted at a Reynolds number of 2.0 million and at Mach numbers ranging from 0.20 to 0.93. Data from the tests have been applied to the calculation of the longitudinal stability and control characteristics and of the lateral control characteristics of an airplane geometrically similar to the model.

NACA RM A9I29

EXPERIMENTAL INVESTIGATION AT SUPERSONIC SPEEDS OF SIDE SCOOPS EMPLOYING BOUNDARY-LAYER SUCTION. Sherman S. Edwards. December 12, 1949. 37p. diagrs., photos. (NACA RM A9I29)

Pressure-recovery characteristics of side scoops employing boundary-layer control by means of suction scoops are described at Mach numbers between 1.36 and 2.01. It is shown that, neglecting the energy expended in boundary-layer removal, total-pressure recovery within 0.05 of that of nose inlets can be attained at free-stream Mach numbers less than 1.8. Reduced pressure recovery occurred with increasing positive angles of attack. Drooping the model forebody with respect to the inlets improved the pressure recovery at angle of attack.

NACA RM A52E06

THE EFFECT OF AN OPERATING PROPELLER ON THE AERODYNAMIC CHARACTERISTICS AT HIGH SUBSONIC SPEEDS OF A MODEL OF A VERTICAL-RISING AIRPLANE HAVING AN UNSWEPT WING OF ASPECT RATIO 3. Fred B. Sutton and Donald A. Buell. November 1954. 90p. diagrs., photos., tabs. (NACA RM A52E06)

Wind-tunnel tests were conducted in the Ames 12-foot pressure wind tunnel through a range of power coefficients at angles of attack up to 16° at Mach numbers from 0.50 to 0.92 at a Reynolds number of 1.7 million. Static aerodynamic characteristics are presented for the complete model and for combinations of model components. The characteristics of the propeller are also shown.

NACA RM A54I17

A FLIGHT INVESTIGATION AT TRANSONIC SPEEDS AND SMALL ANGLES OF ATTACK OF THE AERODYNAMIC CHARACTERISTICS OF A MODEL HAVING A 45° SWEPTBACK WING OF ASPECT RATIO 3 WITH AN NACA 64A006 AIRFOIL SECTION. George H. Holdaway. January 1955. 32p. diagrs., photo., tab. (NACA RM A54I17)

An investigation of the static and dynamic longitudinal aerodynamic characteristics of a model with the subject wing and a 45° sweptback cruciform tail was made at transonic speeds and small angles of attack by a free-fall recoverable-model technique. The load distributions on the fuselage in the vicinity of the wing and aerodynamic characteristics of the exposed wing panels were also determined.

NACA RM A54I22

EFFECTS OF RIGID SPOILERS ON THE TWO-DIMENSIONAL FLUTTER DERIVATIVES OF AIRFOILS OSCILLATING IN PITCH AT HIGH SUBSONIC SPEEDS. James C. Monfort and John A. Wyss. December 1954. 33p. diagrs., photos., tabs. (NACA RM A54I22)

A study was made of the effects of spoilers having fixed heights on the flutter derivatives of two-dimensional airfoils oscillated in pitch at Mach numbers from 0.5 to 0.9, at frequencies from 4 to 40 cycles per second. Airfoils with NACA 65A012, 65A008, 2-008, and 877A008 profiles were used with spoilers of fixed heights, equal to 2-1/2 and 4 percent of the wing chord, affixed at the 70-percent-chord station.

NACA RM A55I19

THE EFFECT OF FLUID INJECTION ON THE COMPRESSIBLE TURBULENT BOUNDARY LAYER - PRELIMINARY TESTS ON TRANSPIRATION COOLING OF A FLAT PLATE AT M = 2.7 WITH AIR AS THE INJECTED GAS. Morris W. Rubesin, Constantine C. Pappas, and Arthur F. Okuno. December 1955. 37p. diagrs. (NACA RM A55I19)

Local values of heat-transfer rate and recovery factor, obtained on a transpiration-cooled flat plate, are presented. Air was injected into a turbulent boundary layer at several rates of flow through a porous flat plate oriented parallel to an air stream. Surface temperatures were maintained near recovery temperature. The Mach number was 2.7 and the Reynolds number range was 1.5 million to 7.0 million.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A55I29

THE EFFECT OF LEADING-EDGE EXTENSIONS OF THE LONGITUDINAL CHARACTERISTICS AT MACH NUMBERS UP TO 0.92 OF A WING-FUSELAGE-TAIL COMBINATION HAVING A 40° SWEPTBACK WING WITH NACA 64A THICKNESS DISTRIBUTION. Fred B. Sutton. January 1956. 52p. diagrs., photos., tabs. (NACA RM A55I29)

The investigation was conducted in the Ames 12-foot pressure wind tunnel. Leading-edge extensions extending from 0.45 semispan to the wing tip and from 0.60 semispan to the wing tip were investigated at a Mach number of 0.25 at a Reynolds number of 8 million and at Mach numbers from 0.25 to 0.92 at a Reynolds number of 2 million.

NACA RM E54I13

EXPERIMENTAL INVESTIGATION OF DRAG OF AFTERBODIES WITH EXITING JET AT HIGH SUBSONIC MACH NUMBERS. Reino J. Salmi. November 1954. 28p. diagrs., photos. (NACA RM E54I13)

The boattail and base pressures of a series of blunt-based conical afterbodies including some ejector configurations were measured at Mach numbers of 0.6 to 0.9 with and without a jet exiting at the base. For both the jet-off and jet-on cases, boattailing was very effective in reducing the drag of the afterbodies. In particular, for simulated jet-engine afterburner-off conditions, the drag of the base that would be formed by iris-type flaps on the secondary shroud was greatly reduced by incorporating a boattail ahead of the base.

NACA RM E54I20

INVESTIGATION OF COMPRESSIBLE FLOW MIXING LOSSES OBTAINED DOWNSTREAM OF A BLADE ROW. Warner L. Stewart. December 1954. 21p. diagrs. (NACA RM E54I20)

The analytical phase of the investigation indicated that increasing the flow velocities into the high subsonic and supersonic levels resulted in an increased mixing loss, with this loss becoming a sizable percentage of the blade viscous loss. Comparison of these results with those obtained experimentally for a transonic turbine stator indicated good agreement at the mean section where nominal two-dimensional flow conditions existed.

NACA RM E55B04

PANEL-FLUTTER INVESTIGATION AT SUPERSONIC SPEEDS OF A PRESSURIZED STRUCTURE FABRICATED OF 0.020-INCH-THICK LAMINATED GLASS-PLASTIC. L. Abbott Leissler. June 1955. 13p. diagrs., photo. (NACA RM E55B04)

An internally pressurized, glass-reinforced plastic shell shaped to simulate a proposed missile fuel cell was investigated at free-stream Mach numbers of 1.5 and 2.0 to determine the minimum pressure differential required to avoid panel flutter. No structural failure occurred with a pressure differential as low as 50 pounds per square foot, the minimum investigated, nor was skin flutter visually observed with either an empty shell at zero angle of attack or a shell half-filled with water at an angle of attack of 10°.

NACA RM E55E06

PREPARATION AND PHYSICAL PROPERTIES OF SOME TRIALKYLBORANES. Louis Rosenblum and Harrison Allen, Jr. November 1955. 19p. diagrs., photos., tab. (NACA RM E55E06)

Triethylborane, tri-n-propylborane, and tri-n-butylborane were prepared by the Grignard method. The first two compounds were distilled to purities of 99.8 and 99.7 mole percent, respectively, but tri-n-butylborane decomposed during distillation. The following physical properties of triethylborane and tri-n-propylborane were determined: (1) freezing point, (2) heat of fusion, (3) boiling point, (4) heat of combustion, (5) refractive index, (6) density, (7) dielectric constant, and (8) infrared spectra.

NACA RM E55H12

INVESTIGATION OF A CERMET GAS-TURBINE-BLADE MATERIAL OF TITANIUM CARBIDE INFILTRATED WITH HASTALLOY C. Charles A. Hoffman. January 1956. 23p. diagrs., photos., tab. (NACA RM E55H12)

A cermet composition was investigated as a potential material for gas-turbine blades. Blades of HS-21 alloy were also operated in the engine simultaneously to provide a basis of comparison. The cermet blades survived as long as approximately 312-1/2 hours at about 1500° F with an average midspan centrifugal stress of approximately 11,500 psi. The alloy blade midspan stress was about 15,300 psi. Because of extensive damage to both types of blade due to external causes, a reliable comparison of operating lives could not be made. The cermet blades tended to fail in the airfoil rather than in the base, although the base was the usual location of failure in a prior study of cold-pressed and sintered cermets of other compositions with the same blade shape.

PRELIMINARY ATTEMPTS AT ISOTHERMAL COMPRESSION OF A SUPERSONIC AIR STREAM. E. Perchonok and F. Wilcox. January 1956. 33p. diagrs., photos., tab. (NACA RM E55I29a)

Guided by analytical predictions, preliminary experments were undertaken in an attempt to achieve isothermal (constant static temperature) compression of a supersonic air stream. When applied to a supersonic inlet diffuser at both $M_0 = 1.9$ and 3.0, the process produced large total-pressure losses due to the momentum exchange between the inlet air stream and the coolant as expected, but the total-pressure increase associated with evaporative cooling was not observed. Tests at $M_0 = 3.0$ with a heated air stream and multipoint upstream injection suggest that some improvement in the process might be obtained with a full-scale inlet at the high stagnation temperature of supersonic flight.

NACA RM H54G20a

ROLLING PERFORMANCE OF THE REPUBLIC YF-84F AIRPLANE AS MEASURED IN FLIGHT. John B. McKay. January 1955. 24p. diagrs., photo., tab. (NACA RM H54G20a)

Flight measurements of the rolling performance of the Republic YF-84F airplane were made at altitudes of 10,000, 25,000, and 40,000 feet. The tests were conducted over a Mach number range from 0.35 to 0.95.

NACA RM L51I04

FLIGHT DETERMINATION OF THE DRAG AND LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A ROCKET-POWERED MODEL OF A 60° DELTA-WING AIRPLANE FROM MACH NUMBERS OF 0.75 TO 1.70. Grady L. Mitcham, Norman L. Crabill, and Joseph E. Stevens. November 1951. 44p. diagrs., photos., tab. (NACA RM L51I04)

A flight investigation of a rocket-powered model of a 60° delta-wing airplane has been conducted to determine the variation of drag with lift and the static and dynamic longitudinal stability parameters from a Mach number of 0.75 to 1.70 at Reynolds numbers of 10×10^6 to 26×10^6.

NACA RM L51I07

TWO-DIMENSIONAL CHORDWISE LOAD DISTRIBUTIONS AT TRANSONIC SPEEDS. Walter F. Lindsey and Richard S. Dick. February 1952. 41p. diagrs., photos. (NACA RM L51I07)

The two-dimensional loadings on nine airfoils are presented at Mach numbers between 0.8 and 1.0. The separate effects of thickness, thickness distribution, and camber are discussed. A method of estimating pressure distributions on symmetrical airfoils at sonic velocity is presented.

NACA RM L52I05

AN ANALYSIS OF THE EFFECT OF A CURVED RAMP ON THE TAKE-OFF PERFORMANCE OF CATAPULT-LAUNCHED AIRPLANES. Wilmer H. Reed, III. November 1952. 28p. diagrs., tab. (NACA RM L52I05)

The possibility of improving take-off performance of catapult-launched airplanes by means of a curved ramp installed forward of the catapult-release point and designed to give the catapulted airplane an initial upward vertical velocity and a nose-up pitching velocity has been analyzed.

NACA RM L52I05a

EXPLORATORY ROCKET FLIGHT TESTS TO INVESTIGATE THE USE OF A FREELY SPINNING MONOPLANE TAIL FOR STABILIZING A BODY. Paul E. Purser and Joseph E. Stevens. October 1952. 25p. diagrs., photos., tab. (NACA RM L52I05a)

Exploratory rocket flight tests have been made to determine the feasibility of stabilizing a body such as a missile, rocket, bomb, or jettisonable external store by the use of freely spinning monoplane fins instead of the usual cruciform or triform fin arrangements. An analysis of the effects of rolling on longitudinal and directional stability of aircraft (NACA TN 1627) which had indicated that such a device could provide stability was verified qualitatively by the flight tests.

NACA RM L52I29

TOTAL-PRESSURE AND SCHLIEREN STUDIES OF THE WAKES OF VARIOUS CANARD CONTROL SURFACES MOUNTED ON A MISSILE BODY AT A MACH NUMBER OF 1.93. William B. Boatright. November 1952. 47p. photos., diagrs. (NACA RM L52I29)

Studies of the wake behind various canard control surfaces of equal span mounted on a missile body have been made at a Mach number of 1.93. These studies were made for eight constant-span control surfaces of varying plan form, thickness, and section by means of total-pressure surveys at a location corresponding to a rearward ram-jet-engine inlet location and by means of plan-view schlieren photographs of the path of the core of the rolled-up vortex sheet from the canard control surfaces. The effect of body-mounted rocket boosters on the pressure field was determined for three control surfaces, as was the effect of end plates attached to the tips of one of the control surfaces.

NACA RM L52I30

AERODYNAMIC CHARACTERISTICS EXTENDED TO HIGH ANGLES OF ATTACK AT TRANSONIC SPEEDS OF A SMALL-SCALE 0° SWEEP WING, 45° SWEPT-BACK WING, AND 60° DELTA WING. Harleth G. Wiley. November 1952. 26p. diagrs. (NACA RM L52I30)

This paper presents the aerodynamic characteristics through high angles of attack and at transonic speeds of a 0° sweep wing, a 45° sweptback wing, and a 60° delta wing. Lift, drag, pitching moment, and bending moment were obtained over an angle-of-attack range of 0° to approximately 60° over a Mach number range of 0.6 to 1.1. The effects of leading-edge roughness on the 0° sweep wing, a constant-thickness flat-plate airfoil section on the 45° sweptback wing, and a fuselage on the 60° delta wing were briefly investigated.

NACA RM L53F01

A WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF A FULL-SCALE SUPERSONIC-TYPE THREE-BLADE PROPELLER AT MACH NUMBERS OF 0.96. Albert J. Evans and George Liner. July 1953. 61p. diagrs., photo. (NACA RM L53F01)

This paper contains the results of an investigation of a full-scale supersonic-type three-blade propeller in the Langley 16-foot transonic tunnel with a 6000-horsepower propeller dynamometer. The tests covered a range of blade angles from 20.2° to 60.2° at forward Mach numbers up to 0.96. The effects of compressibility on the aerodynamic characteristics of the propeller and comparisons of the experimental results with calculated results are presented.

NACA RM L53I01

SOME EXPERIMENTAL EFFECTS OF AFTERBODY SHAPE ON THE ZERO-LIFT DRAG OF BODIES FOR MACH NUMBERS BETWEEN 0.8 AND 1.3. William E. Stoney, Jr. October 1953. 24p. diagrs., photos. (NACA RM L53I01)

Zero-lift drag data were obtained on a series of fin-stabilized bodies differing only in afterbody shape. Three series of afterbodies (fineness ratios 1.78, 3.00, and 5) with varying ratios of base radius to maximum radius (0, 0.458, 0.700, and 1) were combined with a fineness-ratio-7.13 parabolic nose. Both conical and parabolic afterbodies were tested. The models were launched from the Langley helium gun, and data were obtained for Mach numbers from 0.8 to 1.3 and for Reynolds numbers (based on body length) of about 10×10^6. The results indicate that a conical angle of about 4.5° will give the minimum drag for any fineness ratio less than 6, and that the minimum-drag afterbody has a fineness ratio of 6, and that its drag is approximately 30 to 40 percent of that for a square-base body of fineness ratio 0.

NACA RM L53I02

THE INTERPRETATION OF NONLINEAR PITCHING MOMENTS IN RELATION TO THE PITCH-UP PROBLEM. George S. Campbell and Joseph Weil. October 1953. 32p. diagrs., tabs. (NACA RM L53I02)

Equations are presented for calculating the dynamic behavior of airplanes having arbitrarily nonlinear aerodynamic characteristics. Application of the methods derived is directed toward a study of some of the factors affecting the severity of pitch-up motions encountered by airplanes having regions of reduced stability: pitching-moment shape, control movement, dynamic pressure, airplane moment of inertia, and aerodynamic damping. Brief consideration is also given to the effectiveness of automatic stabilization devices in reducing pitch-up severity.

NACA RM L53I04

ROCKET-MODEL INVESTIGATION TO DETERMINE THE HINGE-MOMENT AND NORMAL-FORCE PROPERTIES OF A FULL-SPAN, CONSTANT-CHORD, PARTIALLY BALANCED TRAILING-EDGE CONTROL ON A 60° CLIPPED DELTA WING BETWEEN MACH NUMBERS OF 0.50 AND 1.26. C. William Martz and John W. Goslee. October 1953. 33p. diagrs., photos., tab. (NACA RM L53I04)

Control-force and hinge-moment characteristics were obtained from a free-flight investigation of a rocket-powered research model equipped with 60° sweptback clipped delta wings featuring full-span, constant-chord trailing-edge controls hinged at 40 percent control chord. Data were obtained for angles of attack from ±4° at a Mach number of 1.26 to ±16° at a Mach number of 0.5 and for control-surface deflections up to ±5° between Mach numbers of 0.5 and 1.26. Comparisons are made with linear theory and with other rocket-model data.

NACA RM L53I09

WAKE SURVEYS IN THE SLIPSTREAM OF A FULL-SCALE SUPERSONIC-TYPE THREE-BLADE PROPELLER AT MACH NUMBERS TO 0.96. John M. Swihart and Harry T. Norton, Jr. October 1953. 33p. diagrs., photo. (NACA RM L53I09)

This paper presents the results of an investigation to determine the thrust and thrust loading from wake-survey measurements of a full-scale supersonic-type three-blade propeller at Mach numbers to 0.96. The blade-angle range was from 45.4° to 60.2° measured at the 0.75 radial station over a Mach number range from 0.60 to 0.96. The results of the investigation indicate that operation at blade angles near the design condition produced no sharp compressibility losses at Mach numbers to 0.89. The losses in section thrust coefficient were more severe for the higher blade.

NACA RM L53I21

AN INVESTIGATION AT MACH NUMBER 2.40 OF FLAP-TYPE CONTROLS EQUIPPED WITH OVERHANG NOSE BALANCES. James N. Mueller. November 1953. 95p. diagrs., photos., tab. (NACA RM L53I21)

The results of a two-dimensional pressure distribution investigation at a Mach number of 2.40 of some of the factors affecting the balancing characteristics of flap-type controls equipped with overhang nose balances on a 6-percent-thick symmetrical wing of two afterbody shapes are presented in the form of pressure-distribution diagrams, schlieren photographs, and section aerodynamic coefficients. The factors included are percent overhang, wing-flap gap, fixed transition, flap nose shape, flap trailing-edge thickness, and wing afterbody shape. A method for estimating the loads on the controls is shown to give good results. The Reynolds number of the tests was 0.78×10^6.

NACA RM L53I23a

THE EFFECT OF NOSE RADIUS AND SHAPE ON THE AERODYNAMIC CHARACTERISTICS OF A FUSELAGE AND A WING-FUSELAGE COMBINATION AT ANGLES OF ATTACK. John P. Gapcynski and A. Warner Robins. October 1953. 23p. diagrs. (NACA RM L53I23a)

An investigation has been conducted in the Langley 4- by 4-foot supersonic pressure tunnel to determine the effect of nose blunting on the aerodynamic characteristics of a wing-body combination, and to determine the possible drag reduction of blunt-nosed bodies with the use of spikes and perforated cones. Tests were conducted at a Mach number of 1.61 and a Reynolds number per foot of 4.1×10^6. Limited tests were made at a Mach number of 2.01. The angle-of-attack range was approximately -2° to 10°.

NACA RM L53I28b

CONSIDERATIONS AFFECTING HYDRO-SKI AIRPLANE DESIGN. Kenneth L. Wadlin. November 1953. 14p. diagrs. (NACA RM L53I28b)

This paper discusses the basic concepts of hydro-ski aircraft and how the application of hydro-skis affects supersonic configurations. The interdependency of the fuselage, ski, and possible load-alleviating methods upon the design of hydro-ski airplanes is also considered. Data on fuselages, struts, and lifting surfaces in the planing and submerged condition are presented. Trends indicated by these data and some theoretical work are illustrated and discussed.

NACA RM L54I14

COMPARISON OF EFFECTS OF AILERONS AND COMBINATIONS OF SPOILER-SLOT-DEFLECTOR ARRANGEMENTS ON SPIN RECOVERY OF SWEPT-BACK-WING MODEL HAVING MASS DISTRIBUTED ALONG THE FUSELAGE. Frederick M. Healy and Walter J. Klinar. November 1954. 18p. diagrs., photo., tabs. (NACA RM L54I14)

An investigation has been made in the Langley 20-foot free-spinning tunnel to determine the effectiveness of a lateral-control system employing spoilers and deflectors as compared with ailerons in bringing about recoveries from spins of a model of a 35° swept-wing fighter loaded heavily along the fuselage.

NACA RM L54I15

DESIGN AND EVALUATION OF A TURBOJET EXHAUST SIMULATOR, UTILIZING A SOLID-PROPELLANT ROCKET MOTOR, FOR USE IN FREE-FLIGHT AERODYNAMIC RESEARCH MODELS. Carlos A. deMoraes, William K. Hagginbothom, Jr., and Ralph A. Falanga. December 1954. 25p. diagrs., photos. (NACA RM L54I15)

A method has been developed for modifying a rocket motor so that its exhaust characteristics simulate those of a turbojet engine. The analysis necessary to the design, a typical example, and the tests from which the designs were evaluated are presented. Although applied to solid propellant in the present case, the technique can be applied to any installation where the desired jet total pressure is appreciably less than that of the combustion or reaction camber.

NACA RM L54I19

FLUTTER INVESTIGATION OF A TRUE-SPEED DYNAMIC MODEL WITH VARIOUS TIP-TANK CONFIGURATIONS. John L. Sewall, Robert W. Herr, and William B. Igoe. March 1955. 80p. diagrs., photos., tabs. (NACA RM L54I19)

A 1/6-scale dynamic model, equipped with wing tip tanks and representative of current unswept-wing fighter-type airplanes of conventional plan form, was tested for flutter in the Langley 16-foot transonic tunnel. The wing was of spar-balsa segment-type construction and was dynamically scaled to flutter at the same speed as a typical full-scale configuration, thus avoiding the usual limitations imposed by compressibility. A device for arresting flutter by providing for a quick shift in the tip-tank center of gravity was located in each tip tank and proved to be very effective in stopping symmetric flutter for cases when the tip-tank center of gravity was shifted forward of the wing elastic axis. The flutter problem for which this model was designed was concerned with the effects of external stores, and, in general, the results obtained concur with the results of previous studies of the problem. A conventional Rayleigh-Ritz type of flutter analysis predicted flutter speeds that were excessively conservative with respect to experiment as the tip-tank center of gravity approached the elastic axis.

NACA RM L54I30

FLOW AND FORCE CHARACTERISTICS OF 2-PERCENT-THICK AIRFOILS AT TRANSONIC SPEEDS. Walter F. Lindsey and Emma Jean Landrum. January 1955. 74p. diagrs., photos. (NACA RM L54I30)

A two-dimensional investigation utilizing pressure-distribution measurements and schlieren photographs has been made of the flow and force characteristics of slab-sided airfoils of 2-percent thickness at transonic Mach numbers. The aerodynamic characteristics and an analysis of the flow past the models are presented. The results are compared with previous tests on airfoils of 4-percent thickness and greater, and show that at high subsonic Mach numbers additional improvements in aerodynamic characteristics were obtained with the 2-percent-thick airfoils.

NACA RM L54L16

STUDY OF SOME EFFECTS OF STRUCTURAL FLEXIBILITY ON THE LONGITUDINAL MOTIONS AND LOADS AS OBTAINED FROM FLIGHT MEASUREMENTS OF A SWEPT-WING BOMBER. James J. Donegan and Carl R. Huss. May 1955. 53p. diagrs., tabs. (NACA RM L54L16)

Some measurements obtained during elevator pulse maneuvers with a Boeing B-47A airplane in the Mach number range from 0.62 to 0.82 are analyzed to obtain frequency responses in pitching velocity and normal load factor up to frequencies of 43 radians per second. Transfer coefficients and longitudinal stability derivatives are obtained. Effects of structural flexibility were examined by considering the configuration with three different amounts of flexibility and comparing the maximum responses of each to the same inputs.

NACA RM L55B02

PRELIMINARY RESULTS FROM FLIGHT MEASUREMENTS IN GRADUAL-TURN MANEUVERS OF THE WING LOADS AND THE DISTRIBUTION OF LOAD AMONG THE COMPONENTS OF A BOEING B-47A AIRPLANE. T. V. Cooney, William H. Andrews, and William A. McGowan. June 1955. 20p. diagrs., photo., tab. (NACA RM L55B02)

Preliminary results are presented of strain-gage measurements of the wing loads and distribution of load among the components of the Boeing B-47A airplane in gradual-turn maneuvers at altitudes from 15,000 to 35,000 feet and covering a Mach number range from 0.44 to 0.80.

NACA RM L55I16

THE EFFECT OF LEADING-EDGE DROOP UPON THE PRESSURE DISTRIBUTION AND AERODYNAMIC LOADING CHARACTERISTICS OF A 45° SWEPTBACK WING AT TRANSONIC SPEEDS. James W. Schmeer. November 1955. 42p. diagrs., photos. (NACA RM L55I16)

An experimental investigation has been made in the Langley 16-foot transonic tunnel to determine the effects of 6° leading-edge droop on the presure distribution and aerodynamic loading characteristics of a 45° sweptback wing. Data were obtained through an angle-of-attack range at Mach numbers of 0.80 to 1.03 with average Reynolds numbers of 5.7×10^6 to 6.3×10^6, respectively. Basic pressure-coefficient distribution, center-of-pressure location, and integrated loading characteristics are compared with similar data for the basic or undrooped wing of a previous investigation. Ink-flow pictures for the wing with leading-edge droop are also presented. The results indicate that leading-edge droop delays the onset of separation on the outboard sections of the wing at high subsonic Mach numbers; the beneficial effects decrease with speed and become negligible above a Mach number of 0.94.

NACA RM L55L23b

HIGH-TEMPERATURE OXIDATION AND IGNITION OF METALS. Paul R. Hill, David Adamson, Douglas H. Foland, and Walter E. Bressette. March 1956. 12p. diagrs. (NACA RM L55L23b)

Spontaneous ignition tests were made of a number of metals used in aircraft construction. Rods and cones were tested in heated subsonic and supersonic air jets and wires were heated in static atmospheres of air and oxygen. Several steels, titanium, and magnesium ignited spontaneously, while stainless steels, Inconel, aluminum, and copper did not.

NACA RM L56C23a

FLIGHT INVESTIGATION AND ANALYSIS OF THE WING DEFORMATIONS ON A SWEPT-WING BOMBER DURING ROLLING MANEUVERS. Alton P. Mayo and John F. Ward. October 1956. 48p. diagrs., photo., tabs. (NACA RM L56C23a)

The results of deflection measurements made at six spanwise stations on the wing of a swept-wing jet bomber (Boeing B-47A) during rolling maneuvers are presented in the form of coefficients expressing the deflections due to the aileron loads, the sideslip loads, the wing-flapping inertia loads, and the rolling-velocity loads on the airplane. Comparisons of the experimental deflections and twists with those obtained from theoretical calculations are presented along with a detailed explanation of the procedures used in the analysis of the flight data and in the theoretical calculations.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L56E21a

LIFT-CURVE SLOPES DETERMINED IN FLIGHT ON A FLEXIBLE SWEPT-WING JET BOMBER. William S. Aiken, Jr., and Raymond A. Fisher. December 1956. 49p. diagrs., photos., tabs. (NACA RM L56E21a)

An analysis is made of the effects of Mach number and dynamic pressure on the lift-curve slope of a large flexible swept-wing jet-propelled airplane by using flight measurements of normal acceleration and angle of attack with auxiliary instrumentation as needed. The methods and procedures used to correct the flight measurements (obtained in abrupt push-pull maneuvers) and to convert the flight test data to equivalent rigid conditions for comparison with rigid-model wind-tunnel tests are described in detail. The airplane angle of zero lift and the airplane-less-tail angle of zero lift for the Mach number range of the flight tests (0.42 to 0.81) are also presented.

NACA RM L56H29a

DYNAMIC MODEL INVESTIGATION OF TWO TAIL-SITTER VERTICALLY RISING AIRPLANES TO DETERMINE THE ALTITUDE REQUIRED TO APPROACH NORMAL-FLIGHT CONDITIONS AFTER POWER FAILURE IN HOVERING FLIGHT. Walter J. Klinar and L. Faye Wilkes. November 1956. 15p. diagrs., tabs. (NACA RM L56H29a)

An investigation has been conducted utilizing dynamic models to determine the altitude required for models of two designs that take off and land vertically to turn over and nose into the direction of flight after power failure during hovering flight. Brief computations were also made to attempt to project the flights to the point where normal gliding flight was obtained.

NACA RM L56J02

HORIZONTAL-TAIL PARAMETERS AS DETERMINED FROM FLIGHT-TEST TAIL LOADS ON A FLEXIBLE SWEPT-WING JET BOMBER. William S. Aiken, Jr., and Raymond A. Fisher. January 1957. 42p. diagrs., photos., tabs. (NACA RM L56J02)

An analysis is made of horizontal-tail loads measured by means of strain gages in flight on a flexible multiengined jet-propelled swept-wing medium bomber to determine the horizontal-tail angle of attack, and elevator deflection parameters and centers of pressure of loads on the tail due to angles of attack and elevator deflection. Comparison of flight-determined parameters with available low-speed wind-tunnel data indicated excellent agreement, and the locations of the centers of pressure of the loads were in reasonable agreement with predictions. Least-squares curve-fitting procedures are used, and a method is developed for determining zero shifts for the strain-gage-measured horizontal-tail loads.

NACA RM L56L05

FLIGHT INVESTIGATION AND THEORETICAL CALCULATIONS OF THE FUSELAGE DEFORMATIONS OF A SWEPT-WING BOMBER DURING PUSH-PULL MANEUVERS. Alton P. Mayo. March 1957. 51p. diagrs., photo., tabs. (NACA RM L56L05)

The results of fuselage-deflection measurements at three stations on the fuselage of a swept-wing bomber (Boeing B-47A) during 12 push-pull maneuvers are presented in the form of coefficients expressing the deflection due to the normal-acceleration loads, the pitching angular-acceleration loads, the pitching angular-velocity loads, and the combined effect of zero-lift loads, fuselage dead weight, and landing-gear reactions. Comparisons are made between the experimental deflection coefficients and those obtained from theoretical calculations. An outline of the procedures used to obtain the experimental and the theoretical coefficients is presented.

NACA RM L57B19

AN ANALYSIS OF VERTICAL-TAIL LOADS MEASURED IN FLIGHT ON A SWEPT-WING BOMBER AIRPLANE. William A. McGowan and T. V. Cooney. May 1957. 53p. diagrs., photo., tabs. (NACA RM L57B19)

An analysis is presented of vertical-tail loads measured on a swept-wing bomber airplane at altitudes to 35,000 feet and Mach numbers to 0.82. Flight data obtained from rudder-step, rudder-pulse, aileron-roll, and steady-sideslip maneuvers were used in the analysis to determine lift-curve slopes, centers of pressure, and wing-fuselage, tail, and airplane static-directional-stability parameters. Results are compared, where possible, with values used in design and with theoretical values. Theoretical values of lift-curve slopes were in agreement with flight values when fuselage flexibility was considered.

NACA RM L57E28

ANALYSIS OF WING LOADS MEASURED ON A FLEXIBLE SWEPT-WING JET BOMBER DURING PUSH-PULL MANEUVERS. Patrick A. Gainer and Paul W. Harper. July 1957. 37p. diagrs., photo., tabs. (NACA RM L57E28)

Some results of a flight-test program of wing-load measurements by strain-gage methods on a flexible, swept-wing medium bomber, the Boeing B-47A, are presented. The data were obtained from symmetrical maneuvers. Results are presented in graphical form and compared with those predicted by aeroelastic theory. Comparisons of results obtained by experimental and theoretical methods indicate that presently available methods are capable of predicting additional and basic wing loads accurately within the range of flight conditions covered.

National Advisory Committee for Aeronautics
Research Abstracts
and
Reclassification Notice

NO. 121 **NOVEMBER 4, 1957**

SPECIAL NOTICE

Recent investigations indicate that errors exist in the data presented in NACA Technical Note 1757 and in NACA Report 933, which superseded the TN. These documents, by Ralph E. Grey, Jr., and H. Dean Wilsted, are entitled "Performance of Conical Jet Nozzles in Terms of Flow and Velocity Coefficients."

Although the recent investigations show that the thrust-measurement system used in the earlier work was inherently inaccurate, available data are insufficient to permit effective revision of the documents. We therefore recommend that existing copies of Report 933 and Technical Note 1757 be discarded.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1288

COOPERATIVE INVESTIGATION OF RELATIONSHIP BETWEEN STATIC AND FATIGUE PROPERTIES OF WROUGHT N-155 ALLOY AT ELEVATED TEMPERATURES. NACA Subcommittee on Power Plant Materials. 1956. ii, 35p. diagrs., photos., tabs. (NACA Rept. 1288. Supersedes TN 3216)

Extensive data are given relating properties of N-155 alloy under static, combined static and dynamic, and completely reversed dynamic stress conditions. Time periods for fracture ranged from 50 to 500 hours at room temperature, 1,000°, 1,200°, 1,350°, and 1,500° F. The work was on a cooperative basis to help clarify the principles governing load-carrying ability of heat-resistant alloys at temperatures and conditions where both creep and fatigue can occur simultaneously. In view of the uncertainty in interpreting results of various types of fatigue tests, duplicate data were obtained from as many types of fatigue testing machines as could be arranged.

NACA Rept. 1296

A THEORETICAL STUDY OF THE AERODYNAMICS OF SLENDER CRUCIFORM-WING ARRANGEMENTS AND THEIR WAKES. John R. Spreiter and Alvin H. Sacks. 1957. ii, 31p. diagrs., photos., tabs. (NACA Rept. 1296. Supersedes TN 3528)

A theoretical study is made of the pressures, loadings, forces, and vortex wake associated with certain cruciform wing arrangements. For 45° bank, the wake of a cruciform wing is treated numerically with 40 vortices and analytically with 4 vortices. Comparisons are made with water-tank measurements, and the calculation of loads on cruciform tails by reverse flow is considered.

NACA Rept. 1306

BODIES OF REVOLUTION HAVING MINIMUM DRAG AT HIGH SUPERSONIC AIRSPEEDS. A. J. Eggers, Jr., Meyer M. Resnikoff, and David H. Dennis. 1957. ii, 12p. diagrs., photos. (NACA Rept. 1306. Supersedes TN 3666)

Newtonian impact theory is used to determine body shapes of minimum drag under various combinations of the conditions of given body length, base diameter, surface area, and volume. In addition an estimate is made of centrifugal forces, and their effect on the

CURRENT NACA RESEARCH REPORTS

minimum-drag shapes is considered. An experimental investigation carried out in the Ames 10- by 14-inch supersonic wind tunnel on a family of bodies, including two of the minimum-drag shapes, is found to provide a substantiation of the analysis.

NACA RM E57G18

NONMETALLIC MATERIAL COMPATIBILITY WITH LIQUID FLUORINE. Harold G. Price, Jr., and Howard W. Douglass. October 1957. 7p. tab. (NACA RM E57G18)

Static tests were performed at -320° F and atmospheric pressure and at -320° F and 1500 pounds per square inch gage. These tests showed less reactivity than was observed in previous tests with gaseous fluorine. In general, it was found that reactivity decreased as temperature and pressure decreased.

NACA TN 3290

ON THE MINIMIZATION OF AIRPLANE RESPONSES TO RANDOM GUSTS. Murray Tobak. October 1957. 71p. diagrs. (NACA TN 3290)

Exact theoretical responses in normal acceleration and pitching velocity to step and harmonic gusts are calculated for the rectangular wing flying at Mach number 1.2. These are used to assess the validity of approximate solutions. Alleviation of the airplane's response to random gusts is studied by means of optimum filter theory. The transfer function is derived of a control system that minimizes a linear combination of the airplane's mean-square normal acceleration and mean-square pitching velocity. Results of computations indicate the system may cause significant reductions of both motions.

NACA TN 4018

INFLUENCE OF TURBULENCE ON TRANSFER OF HEAT FROM CYLINDERS. J. Kestin and P. F. Maeder, Brown University. October 1957. 78p. diagrs., tabs. (NACA TN 4018)

This report deals with the problem of the influence of free-stream turbulence on the transfer of heat from a cylinder in forced convection at very low Mach numbers but at large Reynolds numbers. An attempt is made to determine whether the sole influence of turbulence is to shift the point of laminar separation in subcritical flow, or the point of transition in supercritical flow, and thus effect a change in the rate of heat transfer. It is shown that this is not the case and that varying the free-stream turbulence affects local rates of heat transfer.

NACA TN 4027

APPLICATION OF OBLIQUELY MOUNTED STRAIN GAGE TO MEASUREMENT OF RESIDUAL STRESSES IN DISKS. M. H. Hirschberg, R. H. Kemp, and S. S. Manson. September 1957. 18p. diagrs., photo. (NACA TN 4027)

A simple method is presented whereby the residual stress distribution in a disk can be determined. The residual tangential stresses are measured with the aid of the obliquely mounted strain gage when the disk is cut in the recommended manner. This procedure consists of making several preliminary radial saw cuts to reduce the overall residual stress level and then one final diametral saw cut ajacent to the mounted strain gages through the plane where the residual tangential stress is desired. The residual radial stresses are then calculated from the measured residual tangential stresses. Results of measurements on overspeeded disks compare favorably with the calculated values.

NACA TN 4030

EXPERIMENTAL INVESTIGATION OF CERMET TURBINE BLADES IN AN AXIAL-FLOW TURBOJET ENGINE. William C. Morgan and George C. Deutsch. October 1957. 20p. photos., tab. (NACA TN 4030)

In 16 tests to evaluate cermet blades in an axial-flow engine, a maximum blade life of 150 hours at maximum conditions of operation was obtained. Chipping in the tip region was a common characteristic in blade failures. Analysis indicates two probable causes of failure, impact and fatigue. Elimination of excessive carbon in the combustion chambers and avoiding conditions of extreme vibration made an improvement in test blade life.

NACA TN 4034

EFFECT OF FLUID-SYSTEM PARAMETERS ON STARTING FLOW IN A LIQUID ROCKET. Richard P. Krebs. September 1957. 38p. diagrs., tab. (NACA TN 4034)

Analysis shows the time rate of change of the main-valve area to have a large effect on the response time of the main flow and on the maximum value of the drop in head between the propellant tank and the suction side of the pump. This suppression head is directly proportional to the length of the suction line, and inversely proportional to the area of the line and the total valve operating time. Friction, tank head, and length of line from pump to rocket chamber have little effect on flow response or maximum suppression head when the total valve operating time is about 0.1 second.

CURRENT NACA RESEARCH REPORTS

NACA TN 4035

IMPINGEMENT OF CLOUD DROPLETS ON 36.5-PERCENT-THICK JOUKOWSKI AIRFOIL AT ZERO ANGLE OF ATTACK AND DISCUSSION OF USE AS CLOUD MEASURING INSTRUMENT IN DYE-TRACER TECHNIQUE. R. J. Brun and Dorothea E. Vogt. September 1957. 52p. diagrs., tabs. (NACA TN 4035)

The trajectories of droplets in the air flowing past a 36.5-percent-thick Joukowski airfoil at zero angle of attack were determined. The amount of water in droplet form impinging on the airfoil, the area of droplet impingement, and the rate of droplet impingement per unit area on the airfoil surface were calculated from the trajectories and cover a large range of flight and atmospheric conditions. With the detailed impingement information available, the 36.5-percent-thick Joukowski can serve the dual purpose of use as the principal element in instruments for making measurements in clouds and of a basic shape for estimating impingement on a thick streamlined body.

NACA TN 4045

ELLIPTIC CONES ALONE AND WITH WINGS AT SUPERSONIC SPEEDS. Leland H. Jorgensen. October 1957. 55p. diagrs., photos. (NACA TN 4045)

The results of an experimental investigation to determine the aerodynamic characteristics of elliptic cones alone and in combination with triangular wings are presented. Data for Mach numbers 1.97 and 2.94 and a Reynolds number of 8×10^6 (based on cone length) show that there are distinct aerodynamic advantages to the use of elliptic instead of circular cones. Comparisons of theory with experiment are made.

NACA TN 4073

TABLES FOR THE NUMERICAL DETERMINATION OF THE FOURIER TRANSFORM OF A FUNCTION OF TIME AND THE INVERSE FOURIER TRANSFORM OF A FUNCTION OF FREQUENCY, WITH SOME APPLICATIONS TO OPERATIONAL CALCULUS METHODS. Carl R. Huss and James J. Donegan. October 1957. 205p. tabs. (NACA TN 4073)

A set of tables is presented which provides a means for the numerical transfer of data between the time and frequency domain by use of the Fourier transform and inverse Fourier transform. Several applications to operational methods are discussed briefly.

NACA TN 4091

EXPERIMENTAL INVESTIGATION OF TRANSPIRATION COOLING FOR A TURBULENT BOUNDARY LAYER IN SUBSONIC FLOW USING AIR AS A COOLANT. William E. Brunk. October 1957. 35p. diagrs. (NACA TN 4091)

Tests were run for both constant coolant-flow rate and constant wall temperature along a flat porous plate. The results, which indicate a definite decrease in wall temperature along the plate with increase in coolant flow, are in qualitative agreement with a theory for transpiration cooling with a turbulent boundary layer.

NACA TN 4093

INVESTIGATION OF HEAT TRANSFER FROM A STATIONARY AND ROTATING CONICAL FOREBODY. Robert S. Ruggeri and James P. Lewis. October 1957. 30p. diagrs., photo., tab. (NACA TN 4093)

Experimental convective heat transfer was determined for a conical forebody (15° half-angle) for free-stream velocities up to 400 feet per second, rotational speeds up to 1200 rpm, angles of attack of 0° and 6°, and for heating conditions of uniform surface temperature and uniform heater input power density. For the turbulent region, the results were in closer agreement with values predicted for two-dimensional bodies than with those predicted for a cone. Effects of rotation were insignificant. For the stationary spinner at 6° angle of attack, the heat-transfer coefficients were 6 to 13 percent greater on the lower surface than on the upper surface. Early boundary-layer transition occurred for all conditions investigated.

NACA TN 4094

EFFECTS OF EXTREME SURFACE COOLING ON BOUNDARY-LAYER TRANSITION. John R. Jack, Richard J. Wisniewski, and N. S. Diaconis. (Presented at Symposium on High-Speed Aerodynamics and Structures, Gainesville, Florida, January 22-24, 1957.) October 1957. 19p. diagrs., photo. (NACA TN 4094)

Boundary-layer transition studies were made on various bodies of revolution at a Mach number of 3.12 and for Reynolds numbers per foot as large as 15×10^6. In general, the data show that extreme surface cooling promotes early transition even with favorable pressure gradients and blunt leading edges. The effects of surface finish were small with moderate cooling, but were quite large with extreme cooling.

CURRENT NACA RESEARCH REPORTS

NACA TN 4095

AN ANALYSIS OF THE EFFECT OF SEVERAL PARAMETERS ON THE STABILITY OF AN AIR-LUBRICATED HYDROSTATIC THRUST BEARING. William H. Roudebush. October 1957. 34p. diagrs., tab. (NACA TN 4095)

Equations are developed for the motion of a gas-lubricated hydrostatic thrust bearing, and solutions are obtained on a digital computer for air as the gas. Systematic investigations are made of various parameters to determine their effect on bearing stability. Bearing pad volume and rigidity appear as prime controlling factors.

NACA TN 4096

FLOW-TURNING LOSSES ASSOCIATED WITH ZERO-DRAG EXTERNAL-COMPRESSION SUPERSONIC INLETS. Rudolph C. Meyer. October 1957. 18p. diagrs. (NACA TN 4096)

An analysis based on momentum and continuity considerations is used to evaluate the total-pressure recovery of zero-wave-drag external-compression inlets for the Mach number range from 1.0 to 4.0. The geometry of such inlets can cause a significant loss in inlet total-pressure recovery which arises in the process of turning the flow back to the axial direction after supersonic compression. Some consideration is given to wind-tunnel blockage calculations in which the model drag enters as a parameter, and a criterion is developed which supplements the usual Kantrowitz condition.

NACA TN 4098

PROPELLANT VAPORIZATION AS A CRITERION FOR ROCKET-ENGINE DESIGN; CALCULATIONS USING VARIOUS LOG-PROBABILITY DISTRIBUTIONS OF HEPTANE DROPS. Richard J. Priem. October 1957. 29p. diagrs., tab. (NACA TN 4098)

Vaporization rates of n-heptane sprays in a rocket combustion chamber were computed for various log-probability distributions and mass-median drop sizes of the spray and for an engine operating with various injection velocities, final gas velocities, initial fuel temperatures, and chamber pressures. Incomplete vaporization of a small number of large drops may be responsible for the loss in engine performance. Experimental engine performance agrees with the calculations for a spray having a geometric standard deviation of 2.5 and mass-median drop radii of 70 to 280 microns, depending on the type of injector. The calculations of the percent of fuel vaporized are correlated with an effective chamber length.

NACA TN 4099

HEAT TRANSFER AND BOUNDARY-LAYER TRANSITION ON TWO BLUNT BODIES AT MACH NUMBER 3.12. N. S. Diaconis, Richard J. Wisniewski, and John R. Jack. October 1957. 31p. diagrs., photo. (NACA TN 4099)

Local heat-transfer values were measured on a hemisphere-cone-cylinder and a 120°-included-angle cone-cylinder at a Mach number of 3.12. Experimental values of the Stanton number parameter on both bodies agreed well with theoretical predictions with a surface roughness <16 microinches. The heat-transfer parameters on the hemisphere increased with surface roughness; the increase correlated for the test data on the basis of roughness Reynolds number. Transition studies indicated that transition Reynolds number increased with wall temperature. This phenomenon was influenced by unit Reynolds number and surface roughness on the hemisphere-cone-cylinder.

NACA TN 4101

EFFECT OF LUBRICANT VISCOSITY ON ROLLING-CONTACT FATIGUE LIFE. Thomas L. Carter. October 1957. 25p. diagrs., photo., tabs. (NACA TN 4101)

The rolling-contact fatigue spin rig was used to obtain life data for groups of steel balls lubricated with a series of paraffin-base mineral oils of varying viscosity. AISI M-1 balls were tested at 100° F and a calculated maximum compressive Hertz stress of 725,000 psi. A continuous trend toward longer life with higher lubricant viscosity was observed. Life varied approximately as the 0.2 power of lubricant viscosity.

NACA TN 4105

A METHOD OF COMPUTING THE TRANSIENT TEMPERATURE OF THICK WALLS FROM ARBITRARY VARIATION OF ADIABATIC-WALL TEMPERATURE AND HEAT-TRANSFER COEFFICIENT. P. R. Hill. October 1957. 54p. diagrs., tabs. (NACA TN 4105)

Formulas to determine the transient temperature of thick walls with an arbitrary time variation of adiabatic-wall temperature and heat-transfer coefficient are presented. The special cases of the thin wall and the infinitely thick wall are also discussed. A simple formula for determining the heat flow from a known temperature history is also given. Heat transfer in a direction parallel to the surface is assumed to be negligible and constant wall properties are assumed.

CURRENT NACA RESEARCH REPORTS

NACA TN 4112

GENERALIZED MASTER CURVES FOR CREEP AND RUPTURE. George J. Heimerl and Arthur J. McEvily, Jr. October 1957. 31p. diagrs., tab. (NACA TN 4112)

The similarity of Larson-Miller master curves for creep rate, rupture life, and creep strain is shown for a number of materials. By the use of the approximate invariance of the product of creep rate and rupture life, the individual master curves are generalized into a single curve which is the same as the master curve for rupture. From this master curve, the creep rate and various amounts of creep strain can be predicted.

NACA TN 4113

STUDY OF PRESSURE DISTRIBUTIONS ON SIMPLE SHARP-NOSED MODELS AT MACH NUMBERS FROM 16 TO 18 IN HELIUM FLOW. Wayne D. Erickson. October 1957. 42p. diagrs., photos. (NACA TN 4113)

Experimental pressure distributions have been obtained on some simple sharp-nosed aerodynamic shapes in helium flow at Mach numbers from 16 to 18. Temperature recovery factors are also presented. The results are compared with theory which accounts for the shock—boundary-layer interaction. Tunnel-calibration results are also shown.

NACA TN 4114

WEIGHT-STRENGTH STUDIES OF STRUCTURES REPRESENTATIVE OF FUSELAGE CONSTRUCTION. James P. Peterson. October 1957. 47p. diagrs., tab. (NACA TN 4114)

Weight-strength plots, suitable for use in strength and weight analyses in the preliminary design of aircraft construction, are presented for cylindrical shells in bending. Of the types of stiffening considered, sandwich-type stiffening is found to be the most effective, and no decided advantage is found between longitudinal and waffle-like stiffening for minimum-weight designs within the range of structural configurations considered. The ratio of compressive-yield stress to density of material is found to be the most important material parameter for sandwich-type shells, while the density of the material is found to be equally as important for shells with longitudinal or waffle-like stiffening.

NACA TN 4115

THEORY OF AIRCRAFT STRUCTURAL MODELS SUBJECT TO AERODYNAMIC HEATING AND EXTERNAL LOADS. William J. O'Sullivan, Jr. September 1957. 48p. (NACA TN 4115)

The adequacy of an aircraft structure to withstand simultaneously the external loads and aerodynamic heating encountered in supersonic flight is examined by means of a structural model. By dimensional analysis it is shown that a structural model can be built which has the required similitude with respect to flow of heat through it, thermal stresses and deformations, and stresses and deformations due to external loads. For the conditions of negligible angular velocity and angular acceleration, the requisite heating and cooling of the model in simulation of flight of the aircraft is shown to be producible automatically by aerodynamic means without knowledge of the heat transfer to each point on the surface. The simultaneously imposed aerodynamic forces are determined so that the model may be subjected to the requisite external loads for simulation of external load-produced stresses and deformations.

NACA TN 4116

WIND-TUNNEL INVESTIGATION AT LOW SPEEDS TO DETERMINE FLOW-FIELD CHARACTERISTICS AND GROUND INFLUENCE ON A MODEL WITH JET-AUGMENTED FLAPS. Raymond D. Vogler and Thomas R. Turner. September 1957. 48p. diagrs., photos. (NACA TN 4116)

Results are presented of a wind-tunnel investigation made at low speeds to determine the flow-field characteristics and ground influence on an airplane model having an untapered, unswept wing with an aspect ratio of 8.3 equipped with jet-augmented flaps deflected 55° and 85°. The jet-momentum coefficients covered a range representative of that of the output of current jet airplanes. The adverse effects of the ground increase rapidly as the wing approaches the ground, as the flap-deflection angle increases, or as the momentum coefficient increases.

NACA TN 4117

EXPERIMENTAL INVESTIGATION OF LIFT, DRAG, AND PITCHING MOMENT OF FIVE ANNULAR AIRFOILS. Herman S. Fletcher. October 1957. 25p. diagrs., photos. (NACA TN 4117)

Results are presented of tests made to determine the lift, drag, and pitching-moment characteristics of a family of annular airfoils. The five annular airfoils tested covered aspect ratios of 1/3, 2/3, 1.0, 1.5, and 3.0. Estimated lift-curve slopes and induced drag coefficients are presented and compared with experimental values.

CURRENT NACA RESEARCH REPORTS

NACA TN 4121

THEORY AND APPARATUS FOR MEASUREMENT OF EMISSIVITY FOR RADIATIVE COOLING OF HYPERSONIC AIRCRAFT WITH DATA FOR INCONEL AND INCONEL X. William J. O'Sullivan, Jr., and William R. Wade. October 1957. ii, 48p. diagrs., photos. (NACA TN 4121)

The importance of radiation as a means of cooling high-supersonic- and hypersonic-speed aircraft is discussed to show the need for measurements of the total hemispherical emissivity of surfaces. The theory underlying the measurement of the total hemispherical emissivity of surfaces is presented, readily duplicable apparatus for performing the measurements is described, and measurements for stably oxidized Inconel and Inconel X are given for the temperature range from 600° F to 2,000° F.

NACA TN 4122

EXTERNAL INTERFERENCE EFFECTS OF FLOW THROUGH STATIC-PRESSURE ORIFICES OF AN NACA AIRSPEED HEAD AT A MACH NUMBER OF 3. Norman S. Silsby. October 1957. 12p. diagrs. (NACA TN 4122)

Wind-tunnel tests have been made to determine the static-pressure error resulting from external interference effects of flow through the static-pressure orifices of an NACA airspeed head at a Mach number of 3 at 0° angle of attack. Results were obtained for flow both into and out of the orifices for a range of mass flow from 0 to about 4.2×10^{-6} slugs per second.

NACA TN 4123

ROUGH-WATER IMPACT-LOAD INVESTIGATION OF A CHINE-IMMERSED V-BOTTOM MODEL HAVING A DEAD-RISE ANGLE OF 10°. Melvin F. Markey and Thomas D. Carpini. October 1957. 32p. diagrs., photos., tab. (NACA TN 4123)

A hydrodynamic rough-water impact-loads investigation of a fixed-trim V-bottom float with a beam-loading coefficient of 5.78 and dead-rise angle of 10° was made at the Langley impact basin. The size of the waves varied from approximately 10 to 60 feet in length and 1 to 2 feet in height. Time histories were obtained showing the position of the model relative to the wave throughout the impact and typical examples are presented. The load coefficient was found to vary primarily with the slope of the impacting wave.

NACA TN 4127

THE MEASUREMENT OF PRESSURE ALTITUDE ON AIRCRAFT. William Gracey. October 1957. 25p. diagrs., tabs. (NACA TN 4127)

The various errors which determine the accuracy of an altimeter system are discussed and numerical values are assigned to each error. A statistical method for combining the individual errors is described. The overall errors of altimeter installations are calculated for Mach numbers up to 1.0 and altitudes up to 40,000 feet. An indication of the means by which some of the errors can be reduced is given. Various systems of barometric reference are also discussed.

N-50060*

Royal Aircraft Establishment (Gt. Brit.)
EFFECTS OF ELEVATOR CIRCUIT STIFFNESS ON THE LOADING CONDITIONS IN LONGITUDINAL MANOEUVRES. D. R. Puttock. Mar. 1957. 31p. diagrs., tab. RAE Structures 220.
(Ask for N-50060*)

An investigation of the effects of elevator circuit stiffness on the loading conditions of an aircraft in a rapid pilot-induced pull-out maneuver is presented with a particular reference to the airworthiness aspects. The solution to the problem is given in general terms; it includes expressions for the incremental elevator angle, stick force, normal acceleration at the center of gravity, and the tail-plane load in response to a chosen sequence of pilot-induced stick movements to initiate a rapid pull-out maneuver. The solution is a complex one and the influence of significant parameters such as the degree of mass balance of the elevator circuit, the forward speed of the aircraft, and the rate of application of the stick movement is discussed in relation to a numerical example. Brief mention is made of further implications of this investigation.

Advisory Group for Aeronautical Research and Development. TIRE-RUNWAY BRAKING FRICTION COEFFICIENTS. Melvin N. Gough, Richard H. Sawyer, and James P. Trant, Jr. (Presented at 8th joint session of AGARD Flight Test Techniques and Wind Tunnel and Model Testing Panels, February 20-25, 1956, Rome, Italy.) February 1956. iv, 20p. diagrs., photos. AGARD Report 51. (Ask for N-41829*)

A brief review is made of the problem of obtaining adequate tire-runway braking friction coefficients for use in determining the stopping distances of aircraft in landings. Methods and instrumentation used by the NACA for obtaining friction-coefficient data from full-scale airplane landings are described, and their limitations are discussed. Included also is a description of a friction-measuring cart to be towed over surfaces of interest. This device appears to offer an inexpensive method of obtaining data of the type desired by airport operators to provide information to pilots concerning surface conditions to be encountered in landings.

Advisory Group for Aeronautical Research and Development. A VARIATIONAL APPROACH TO PURE MODE EXCITATION BASED ON CHARACTERISTIC PHASE LAG THEORY. B. M. Fraejis de Veubeke. (Presented at 3rd meeting of AGARD Structures Panel, April 9-17, 1956, Washington, D. C.) April 1956. v, 35p. diagrs. AGARD Report 39. (Ask for N-45138*)

Characteristic phase lag theory is applied to the derivation of an energy principle for pure mode excitation at a resonant frequency. The principle is not restricted to small damping nor to a specific variation of damping coefficients with frequency. Preliminary remarks on structural damping are followed by a discussion of the simplifying assumption which makes the damping matrix proportional to the stiffness matrix. This procedure allows a gradual presentation of the general analysis based on the concept of characteristic phase lag. Both torsional and flexural response of a beam to single point excitation are presented as examples for the influence of internal damping on continuous structures.

Advisory Group for Aeronautical Research and Development. THE MEASUREMENT AND ASSESSMENT OF REPEATED LOADS ON AIRPLANE COMPONENTS. Philip Donely. (Presented at 3rd meeting of AGARD Structures and Materials Panel, April 10-17, 1956, Washington, D. C.) April 1956. vii, 34p. diagrs., tabs. AGARD Report 45. (Ask for N-45472*)

The factors affecting the load statistics of modern airplanes are assessed on the basis of the NACA studies of the repeated load problem. The loads arising from various sources are discussed and their importance to aircraft with various missions are shown to vary. It is shown that much more data are desirable if coordinated load histories for particular aircraft are to be predictable.

N-45617*

Advisory Group for Aeronautical Research and Development. TECHNIQUES FOR TESTING MODELS OF VTOL AND STOL AIRPLANES. John P. Campbell. (Presented at 9th meeting of AGARD Wind Tunnel and Model Testing Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. vi, 31p. diagrs., photos. AGARD Report 61. (Ask for N-45617*)

Describes briefly some of the techniques used by NACA in research on VTOL and STOL airplanes ("vertical take-off and landing" and "short take-off and landing"). Deals mainly with free-flying model technique but a brief description is also given of some of the force-testing techniques.

N-45841*

Advisory Group for Aeronautical Research and Development. DESIGN AND DEVELOPMENT OF THE NORTH AMERICAN AVIATION TRISONIC WIND TUNNEL. W. Daniels, Jr. (Presented at 9th meeting of AGARD Wind Tunnel and Model Testing Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. vi, 47p. diagrs., photos. AGARD Report 67. (Ask for N-45841*)

This tunnel will be the largest blowdown wind tunnel in existence when completed. The large test section (7-ft by 7-ft) and test speed range (Mach 0.2 to 3.5) of the facility will satisfy the requirements for aerodynamic testing to develop modern aircraft and missiles. Models will be large enough to contain all necessary instrumentation and components and produce data which can readily be applied to full-scale conditions. A few major components which are of new or novel design in the wind-tunnel field are the tandem test sections, control valve, mechanism for nozzle control, and tin-can temperature stabilizing material.

N-46129*

Advisory Group for Aeronautical Research and Development. THE DETERMINATION OF AILERON EFFECTIVENESS. R. R. Duddy. (Presented at 9th meeting of AGARD Joint Session Wind Tunnel and Model Testing and Flight Test Techniques Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. v, 8p. diagrs., tab. AGARD Report 73. (Ask for N-46129*)

This note describes two alternative methods of measuring aileron effectiveness in flight for comparison with the results of estimates and wind-tunnel measurements. Results obtained on four aircraft show that the agreement obtained is not particularly good but the tunnel measurements do indicate the reduction in aileron effectiveness to be expected in flight at high lift coefficients on swept-wing aircraft.

Advisory Group for Aeronautical Research and Development. SOME COMMENTS ON HIGH-LIFT TESTING IN WIND TUNNELS WITH PARTICULAR REFERENCE TO JET-BLOWING MODELS. A. Anscombe and J. Williams. (Presented at 9th meeting of AGARD Wind Tunnel and Model Testing Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. vi, 33p. diagrs. AGARD Report 63. (Ask for N-46250*)

This note considers some of the special problems of wind tunnel testing which arise in high-lift work. Discussion is confined to current experience in the R.A.E. and N.P.L. low-speed wind tunnels, and refers mainly to tests on blowing over flaps or jet flaps. Comments are made on suitable size of model, methods of feeding compressed air into models without affecting balance readings, and general test technique. Methods of model construction are not specifically discussed.

Advisory Group for Aeronautical Research and Development. UTILIZATION OF ONLY SLIGHTLY PREPARED TERRAIN. (Utilisation des terrains sommairement amenages.) S. Lefebvre. (Presented at 9th session of AGARD Flight Test Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. vi, 31p. photos. (French text.) AGARD Report 74. (Ask for CN-46307*)

Information abstracted from various tests regarding the investigation of the problems involved in employing aircraft on hastily improvised runways is condensed. Special difficulties encountered in the investigation of the taxiing properties of aircraft on nonhomogeneous surfaces, such as earth runways, are first discussed. Then the behavior of the aircraft, that is, maneuverability on the ground, stability, and performance when taxiing, is dealt with. The influence of utilization of hastily improvised runways on the mechanical behavior of the aircraft is then studied. A summary is given of information drawn from tests.

CN-46309*

Advisory Group for Aeronautical Research and Development. CALIBRATION OF ANGLES OF ATTACK AND SIDESLIP. (Etalonnage d'incidence et de derapage.) A. Boisson. (Presented at 9th session of AGARD Flight Test Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. vii, 35p. diagrs., photos., tabs. (French text.) AGARD Report 77. (Ask for CN-46309*)

Angle of attack is measured by a special pressure head, which detects a pressure difference, and the ratio of this pressure difference to the dynamic pressure is a function of angle of attack. This function is determined experimentally from "incidence calibration" tests. The method of calibration is to measure, during runs at stabilized speeds, the longitudinal trim and the inclination of the flight path. The incidence is the difference between these two parameters. Sideslip is measured in a similar way. These flight-test methods are described.

Advisory Group for Aeronautical Research and Development. NOTES ON THE GROUND-RUN OF JET-PROPELLED AIRCRAFT DURING LANDING AND TAKE-OFF. Guiscardo S. Alias. (Presented at 9th meeting of AGARD Flight Test Techniques Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. vi, 35p. diagrs., tabs. AGARD Report 82. (Ask for N-47793*)

Equations for ground-run distances on an inclined runway which take account of the use of rockets during take-off and reverse thrust and braking parachutes during landing are derived. By dividing the ground-run distance by a "basic" horizontal distance a ratio is obtained which may be used comparatively to analyze the separate effects of various factors. This method is applied to ground-run distances on an inclined runway to examine the possibility of using, under special operational conditions, sloping bare ground or a part of a main road suitably prepared as a "one-way" strip for landing or take-off.

N-48958*

Advisory Group for Aeronautical Research and Development. BRIEF DESCRIPTION OF THE R.A.E. INTERMITTENT SUPERSONIC WIND TUNNEL PLANT. K. G. Winter. (Presented at 9th meeting of AGARD Wind Tunnel and Model Testing Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. v, 14p. diagrs., photos. AGARD Report 66. (Ask for N-48958*)

The plant is vacuum-operated on a closed circuit with storage of the air in a flexible container. The useful Mach number range is up to about 4.5. For the largest of the tunnels (15 in. x 16 in.) the maximum running time is of the order of 20 seconds over the whole Mach number range. Runs of 10 to 15 seconds duration can be made every five minutes.

Advisory Group for Aeronautical Research and Development. ENGLISH ELECTRIC PROPOSED BLOW-DOWN WIND TUNNEL. F. E. Roe. (Presented at 9th meeting of AGARD Wind Tunnel and Model Testing Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. iv, 21p. diagrs. AGARD Report 68. (Ask for N-55071*)

The need for wind-tunnel facilities to fulfill the requirements of both Aircraft and Guided Weapons Divisions of the English Electric Company is discussed. The basic design data for the two tunnels are outlined, and an estimate of the optimum characteristics obtained showing the economic and technical advantage of utilizing a single power source for both tunnels. The performance of such a joint facility is indicated.

N-55072*

Advisory Group for Aeronautical Research and Development. SOME CORRELATIONS OF FLIGHT-MEASURED AND WIND-TUNNEL MEASURED STABILITY AND CONTROL CHARACTERISTICS OF HIGH-SPEED AIRPLANES. Walter C. Williams, Hubert M. Drake, and Jack Fischel, HSFS. (Presented at 9th meeting of AGARD Wind Tunnel and Model Testing Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. vi, 11p. diagrs. AGARD Report 62. (Ask for N-55072*)

Comparisons are made of some of the more important stability and control characteristics of three swept-wing airplanes as measured in flight and in wind tunnels. Wind-tunnel data are used from high-speed closed-throat tunnels, a slotted-throat transonic tunnel, and a supersonic tunnel. It is shown that wind tunnels generally predict all trends of characteristics reasonably well but that there are differences in the actual values of parameters, which could be attributed to differences in the model caused by the method of support. The problem of nonlinearities in derivatives obtained in wind-tunnel tests, of aeroelastic effects, and of inlet effects, is discussed.

NACA RM A9J06

THE EFFECTS OF SCALE AND TEST TECHNIQUE ON THE VALIDITY OF SMALL-SCALE MEASUREMENTS OF THE AERODYNAMIC CHARACTERISTICS OF A WING WITH THE LEADING EDGE SWEPT BACK 63°. L. Stewart Rolls. December 9, 1949. 20p. diagrs., photos. (NACA RM A9J06)

This report presents the results of tests by the NACA wing-flow method of two wings of the same plan form, aspect ratio 3.5, taper ratio 0.25, and leading-edge sweep angle 63°. The lift and pitching-moment characteristics are presented for the Mach number range 0.52 to 1.11 at a corresponding Reynolds number range of 0.39 million to 0.81 million. A comparison with the results of larger scale tests indicated considerable differences in the location of the aerodynamic center. The results of several modifications to the model configuration and test technique made in an attempt to explain the discrepancy are presented.

NACA RM A51F18

A COMPARISON OF THE CALCULATED MAXIMUM MANEUVER-RESPONSE CHARACTERISTICS OF THREE AIR-TO-AIR, BEAM-RIDER, GUIDED MISSILES HAVING DIFFERENT LIFT RATIOS. Howard F. Matthews and Elwood C. Stewart. September 1951. 57p. diagrs., tabs. (NACA RM A51F18)

A comparison was made of the calculated response characteristics to a maximum maneuver of a variable incidence, a canard, and a conventional tail-aft-control missile, which are indicative, respectively, of a high positive, a low positive, and a negative lift ratio. The results showed that the performance for the variable-incidence missile is equal to or slightly better than that of the canard, and the performance of both is better than that of the tail-aft-control missile. Consideration of additional factors such as servo energy, control-deflection interference limit, etc., may, in an overall evaluation, outweigh the small decrease in normal-displacement response time associated with the higher positive lift ratios.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A52H28

INVESTIGATION OF THE DRAG OF VARIOUS AXIALLY SYMMETRIC NOSE SHAPES OF FINENESS RATIO 3 FOR MACH NUMBERS FROM 1.24 TO 3.67. Edward W. Perkins and Leland H. Jorgensen. November 1952. 50p. diagrs., photos. (NACA RM A52H28)

Experimental foredrag measurements at zero angle of attack for various theoretical minimum drag nose shapes, hemispherically blunted cones, and other more common profiles of fineness ratios of about 3 are compared with theoretical results for a Mach number and a Reynolds number range of 1.24 to 3.67 and 2×10^6 to 4×10^6 (based on body length), respectively. The results of experimental pressure distribution measurements are used for the development of an empirical expression for predicting the pressure drag of hemispherically blunted cones.

NACA RM A52J22

THEORETICAL INVESTIGATION OF THE PERFORMANCE OF PROPORTIONAL NAVIGATION GUIDANCE SYSTEMS - EFFECT OF MISSILE CONFIGURATION ON THE SPEED OF RESPONSE. Marvin Abramovitz. January 1953. 20p. diagrs., tabs. (NACA RM A52J22)

The speeds of response attainable with three missile configurations, a variable-incidence-wing, a canard, and a tail-control, in combination with a proportional navigation system are compared. With only rate-of-pitch feedback in the control system, the system speed of response with all three configurations is very nearly the same as that of the missiles alone. However, with normal acceleration feedback also included, the system speed of response with all three configurations is more rapid than that of the missiles alone.

NACA RM A53H17

COMPARISON OF THEORETICAL AND EXPERIMENTAL ZERO-LIFT DRAG-RISE CHARACTERISTICS OF WING-BODY-TAIL COMBINATIONS NEAR THE SPEED OF SOUND. George H. Holdaway. October 1953. 27p. diagrs., tab. (NACA RM A53H17)

Comparison with experiments on a variety of wing-body-tail combinations showed that linear theory predicted the zero-lift drag rise at low supersonic speeds within an accuracy of about 20 percent. Theoretical computations indicate that fuselage alterations to reduce the drag should be examined over the operating range of Mach numbers, also that the drag might be reduced by adding volume to the fuselage before and behind the wing.

NACA RM A53J14a

EFFECTS OF LEADING-EDGE CHORD EXTENSIONS AND AN ALL-MOVABLE HORIZONTAL TAIL ON THE AERODYNAMIC CHARACTERISTICS OF A WING-BODY COMBINATION EMPLOYING A TRIANGULAR WING OF ASPECT RATIO 3 MOUNTED IN A HIGH POSITION AT SUBSONIC AND SUPERSONIC SPEEDS. Benton E. Wetzel and Frank A. Pfyl. January 1954. 35p. diagrs., photo., tabs. (NACA RM A53J14a)

The effect of leading-edge chord extensions on the lift, drag, and pitching moment of a wing-body-tail combination having a 3-percent-thick triangular wing of aspect ratio 3 mounted in a high position, and the control characteristics of an unswept, all-movable horizontal tail were investigated. Results are presented for horizontal-tail deflections varying from $+4^\circ$ to -24°, at Mach numbers of 0.6 through 0.9 and 1.2 through 1.9, and at a Reynolds number of 3.8 million.

NACA RM A54F22

AN EXPERIMENTAL INVESTIGATION OF REDUCTION IN TRANSONIC DRAG RISE AT ZERO LIFT BY THE ADDITION OF VOLUME TO THE FUSELAGE OF A WING-BODY-TAIL CONFIGURATION AND A COMPARISON WITH THEORY. George H. Holdaway. August 1954. 35p. diagrs., photos., tabs. (NACA RM A54F22)

An experimental investigation was made at transonic speeds by the free-fall recoverable-model technique to assess at zero lift the possibilities of reducing the drag-rise coefficients of an unswept wing-body-cruciform-tail combination by adding volume to the fuselage.

NACA RM A55B21

AN EXPERIMENTAL INVESTIGATION OF TWO METHODS FOR REDUCING TRANSONIC DRAG OF SWEPT-WING AND BODY COMBINATIONS. John B. McDevitt. April 1955. 27p. diagrs., photos. (NACA RM A55B21)

An experimental investigation of several wing-body combinations was conducted at transonic speeds. The wing had an aspect ratio of 6 and NACA 64_2A015 sections normal to the 50-percent-chord line which was swept back 35°. One basic (Sears-Haack) body and three modified bodies were tested. Two of the modified bodies were designed to alleviate the adverse interference at the root of the sweptback wing. The third modified body was indented according to Whitcomb's area rule. Both methods resulted in considerable reductions of wave drag at transonic speeds.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A55E11

APPLICATION OF STATISTICAL THEORY TO BEAM-RIDER GUIDANCE IN THE PRESENCE OF NOISE. I - WIENER FILTER THEORY. Elwood C. Stewart. August 1955. 40p. diagrs., tabs. (NACA RM A55E11)

A study has been made of the application of Wiener filter theory to the design of a beam-rider guidance system operating in the presence of glint noise. This theory is used to establish theoretical lower limits of root-mean-square error and desired transfer-function characteristics. Certain modifications necessary in practice are applied to the design of several systems. Consideration is also given to servo energy requirements.

NACA RM A55E11a

APPLICATION OF STATISTICAL THEORY TO BEAM-RIDER GUIDANCE IN THE PRESENCE OF NOISE. II - MODIFIED WIENER FILTER THEORY. Elwood C. Stewart. August 1955. 48p. diagrs., tabs. (NACA RM A55E11a)

An application has been made of Newton's modification of Wiener filter theory to optimize a beam-rider guidance system operating in the presence of glint noise. Results indicate that when the operation of the system is restricted to practical linear ranges, the minimum error attained from this theory closely approaches that for the Wiener theory. The system transfer functions and error performance against noise are given. Requirements on control deflection rates, circuit voltages, and servo energy are discussed.

NACA RM A55J11

A STUDY OF LOCAL-PRESSURE FLUCTUATIONS RELATIVE TO STATIC-PRESSURE DISTRIBUTIONS OF TWO-DIMENSIONAL AIRFOILS AT HIGH SUBSONIC MACH NUMBERS. Charles F. Coe. December 1955. 66p. diagrs., photos. (NACA RM A55J11)

The relationship of local-pressure fluctuations to the time-average static-pressure distribution has been investigated for six symmetrical two-dimensional airfoils. The thickness ratios of the airfoils varied from 12 percent to 4 percent. In addition, the relationship of the total-pressure fluctuations to the time-average total-pressure loss in the wake of an NACA 65A008 airfoil was studied. Results were obtained between Mach numbers of about 0.59 and 0.90 with corresponding Reynolds numbers varying from about 6.3 million to 8.0 million.

NACA RM A55J12

THE EFFECT OF TRAILING-EDGE BLUNTNESS ON THE PERFORMANCE OF A SMALL-SCALE SUPERSONIC PROPELLER AT FORWARD MACH NUMBERS TO 0.92. Fred A. Demele and Carl D. Kolbe. January 1956. 66p. diagrs., photo., tabs. (NACA RM A55J12)

The report presents the aerodynamic characteristics of two 1/12-scale, supersonic-type, three-blade propellers, one having sharp trailing edges and the other having blunt trailing edges. The blunt-trailing-edge propeller had slightly thinner blade sections and the same power absorption capabilities and essentially the same torsional stiffness as the sharp-trailing-edge propeller. The tests covered blade angles from -19° to 56° at forward Mach numbers up to 0.92. In general, slightly higher efficiency was achieved with the blunt-trailing-edge propeller.

NACA RM A55K10

INFLUENCE OF THE BODY FLOW FIELD ON THE ZERO-LIFT WAVE DRAG OF WING-BODY COMBINATIONS MODIFIED IN ACCORDANCE WITH THE TRANSONIC AREA RULE. William A. Page. February 1956. 26p. diagrs. (NACA RM A55K10)

An analysis based upon an approximation to the transonic small-disturbance theory indicates that for a restricted class of indented wing-body combinations the zero-lift wave drag approximates that of the corresponding equivalent body when a Mach number of 1 occurs locally at the wing instead of in the free stream. Comparisons made between the analysis and available experimental data suggest an explanation for some of the anomalous results obtained from tests of indented wing-body combinations.

#NACA RM E51J02, by McAulay

NACA RM E52A24

EXPERIMENTAL INVESTIGATION OF AN AXIAL-FLOW COMPRESSOR INLET STAGE OPERATING AT TRANSONIC RELATIVE INLET MACH NUMBERS. I - OVER-ALL PERFORMANCE OF STAGE WITH TRANSONIC ROTOR AND SUBSONIC STATORS UP TO ROTOR RELATIVE INLET MACH NUMBER OF 1.1. Seymour Lieblein, George W. Lewis, Jr., and Donald M. Sandercock. March 1952. 21p. diagrs., photos. (NACA RM E52A24)

An experimental investigation was conducted on an axial-flow compressor inlet stage consisting of a transonic rotor and subsonic stators. The rotor was designed for a tip speed of 1000 feet per second and an inlet hub-tip radius ratio of 0.525 and had a maximum relative inlet Mach number at the tip of 1.1 at design speed. At design speed of 1000 feet per second, a peak stage adiabatic efficiency of 0.90 was obtained at a corrected weight flow of 44.5 pounds

DECLASSIFIED NACA RESEARCH REPORTS

per second and a pressure ratio of 1.47. Maximum pressure ratio was 1.48 and maximum weight flow was 48.0 pounds per second or 29.2 pounds per second per square foot frontal area. Weight-flow range was generally equivalent to the range of current inlet stages. Stator outlet conditions and general stage performance appeared satisfactory for multi-staging with current stage designs.

NACA RM E52C25

INVESTIGATION OF TURBINES FOR DRIVING SUPERSONIC COMPRESSORS. I - DESIGN AND PERFORMANCE OF FIRST CONFIGURATION. Warner L. Stewart, Harold J. Schum, and Warren J. Whitney. June 1952. 27p. diagrs., photo. (NACA RM E52C25)

A turbine to drive a supersonic compressor was designed and a cold-air model of this configuration operated to determine its performance. At equivalent design operating speed, the cold-air turbine passed 95 percent of design weight flow, and the turbine limiting-loading point was reached at a work slightly less than design. The performance of the turbine is presented in this report together with the design and aerodynamic problems encountered.

NACA RM E52C27

EXPERIMENTAL INVESTIGATION OF AXIAL-FLOW COMPRESSOR INLET STAGE OPERATING AT TRANSONIC RELATIVE INLET MACH NUMBERS. II - BLADE-COORDINATE DATA. George W. Lewis, Jr. June 1952. 9p. diagrs. (NACA RM E52C27)

Supplementary blade-design data including rotor- and stator-blade coordinates and mean-line angles at the leading and the trailing edges are presented for a transonic axial-flow compressor inlet stage.

NACA RM E52E26

INVESTIGATION OF TURBINES FOR DRIVING SUPERSONIC COMPRESSORS. II - PERFORMANCE OF FIRST CONFIGURATION WITH 2.2-PERCENT REDUCTION IN NOZZLE FLOW AREA. Warner L. Stewart, Harold J. Schum, and Robert Y. Wong. July 1952. 14p. diagrs., tab. (NACA RM E52E26)

The experimental performance of a modified turbine for driving a supersonic compressor is presented and compared with the performance of the original configuration to illustrate the effect of small changes in the ratio of nozzle-throat area to rotor-throat area on the performance of turbines designed to operate with both blade rows close to choking. On the basis of the results of this investigation, the ratio of areas is concluded to become especially critical in the design of turbines such as those designed to drive high-speed, high specific-weight-flow compressors where the turbine nozzles and rotor are both very close to choking.

NACA RM E52J08

PERFORMANCE CHARACTERISTICS OF CANARD-TYPE MISSILE WITH WING-MOUNTED NACELLE ENGINES AT MACH NUMBERS 1.5 TO 2.0. Emil J. Kremzier and Joseph Davids. November 1952. 30p. diagrs., tab. (NACA RM E52J08)

Performance characteristics of a complete canard-type missile configuration with two wing-mounted nacelle engines were determined for Mach numbers from 1.5 to 2.0, angles of attack from 0° to 10°, control-surface-deflection angles from -6° to 10°, and a range of engine mass-flow ratios. Overall force and moment characteristics together with engine diffuser performance as affected by the missile components are presented. Addition of the engines increased the configuration lift and drag but decreased the maximum lift-drag ratio to 5.2 at Mach number 2.0 and zero control-surface deflection, and produced a stabilizing effect on the pitching moment about the reference moment center.

NACA RM E53A20

INVESTIGATION OF TURBINES FOR DRIVING SUPERSONIC COMPRESSORS. III - FIRST CONFIGURATION WITH FOUR NOZZLE SETTINGS AND ONE NOZZLE MODIFICATION. Warner L. Stewart, Warren J. Whitney, and Daniel E. Monroe. March 1953. 28p. diagrs., photo., tab. (NACA RM E53A20)

A turbine designed to power a supersonic compressor was investigated with four nozzle settings and one nozzle modification to determine the effect on turbine performance. With the correct ratio of nozzle throat area to rotor effective throat area, the design specific work was obtained near the peak efficiency. From the results of the investigation it was concluded that the convex insweep of the rotor inner wall and high degree of blade taper caused the turbine configuration to have two aerodynamic disadvantages in comparison with a turbine configuration with an axial inner wall at the rotor outlet and little axial taper.

NACA RM E53C02

INVESTIGATION OF TURBINES FOR DRIVING SUPERSONIC COMPRESSORS. IV - DESIGN AND PERFORMANCE OF SECOND CONFIGURATION INCLUDING STUDY OF THREE-DIMENSIONAL FLOW EFFECTS. Warren J. Whitney, Warner L. Stewart, and Harold J. Schum. May 1953. 20p. diagrs., photo., tab. (NACA RM E53C02)

The design and performance of a turbine configuration designed to drive a supersonic compressor are presented herein. The performance results of this turbine, the design of which included the three-dimensional flow effects, are compared with the results obtained from a turbine configuration designed for this application by a conventional technique in which three-dimensional effects were not considered. The comparison demonstrated that proper consideration of the three-dimensional character of the flow can result in satisfactory performance. The performance results of both configurations

DECLASSIFIED NACA RESEARCH REPORTS

are also compared with the results of a three-dimensional analysis made on the two configurations to illustrate the validity of the analysis in predicting three-dimensional flow problems.

NACA RM E53D01

DIFFUSION FACTOR FOR ESTIMATING LOSSES AND LIMITING BLADE LOADINGS IN AXIAL-FLOW-COMPRESSOR BLADE ELEMENTS. Seymour Lieblein, Francis C. Schwenk, and Robert L. Broderick. June 1953. 43p. diagrs., tabs. (NACA RM E53D01)

A simplified limiting-blade-loading parameter for axial-flow-compressor blade elements was derived from application of boundary-layer-theory separation criterion to typical suction-surface velocity distribution of blade element at design angle of attack. Comparison was made between derived diffusion factor and other blade-loading parameters by correlation of loss coefficients against loading parameter for cascade data of NACA 65-series compressor blade sections. Further loss-diffusion factor correlations were made for hub-, tip-, and mean-radius regions of several axial-flow-compressor inlet-stage rotors and stators. Loss-diffusion variation in rotor hub and mean and stator hub, tip, and mean regions compared favorably with cascade results, but rotor tip-region variation was markedly different.

NACA RM E53D24

INVESTIGATION OF AN AXIAL-FLOW-COMPRESSOR ROTOR WITH CIRCULAR-ARC BLADES OPERATING UP TO A ROTOR-INLET RELATIVE MACH NUMBER OF 1.22. William H. Robbins and Frederick W. Glaser. July 1953. 63p. diagrs., photos., tabs. (NACA RM E53D24)

A 14-inch-diameter axial-flow-compressor rotor with a hub-tip diameter ratio of 0.50 was designed and operated to investigate the blade-element characteristics as well as the overall performance of a set of circular-arc rotor blades operating over a range of inlet relative Mach numbers from 0.40 to 0.82 with the inlet guide vanes installed and from 0.44 to 1.22 with the guide vanes removed. The optimum incidence angle appeared to increase as Mach number increased. At the design angle of incidence, the design turning-angle rule predicts accurately the turning at all radial positions except the hub section, where slight underturning resulted. In the rotor without guide vanes, at a tip speed of 1120 feet per second there were indications that the limiting relative Mach number, which was determined to be between 1.10 and 1.20, had been exceeded. Therefore, the overall peak efficiency was reduced approximately 7 percent in this range of Mach number.

NACA RM E53G17

EXPERIMENTAL INVESTIGATION OF AN AXIAL-FLOW COMPRESSOR INLET STAGE OPERATING AT TRANSONIC RELATIVE INLET MACH NUMBERS. III - BLADE-ROW PERFORMANCE OF STAGE WITH TRANSONIC ROTOR AND SUBSONIC STATOR AT CORRECTED TIP SPEEDS OF 800 AND 1000 FEET PER SECOND. Francis C. Schwenk, Seymour Lieblein, and George W. Lewis, Jr. September 1953. 69p. diagrs., photos., tabs. (NACA RM E53G17)

A series of survey tests at two rotor speeds was conducted on an axial-flow compressor inlet stage consisting of a transonic rotor and subsonic stators to permit a detailed analysis of the flow across each of the blade rows. The extensive blade-element data which are presented for the purpose of providing basic design information for this type of stage include the variations with incidence angle of such factors as losses, turning angle, axial velocity ratio, work coefficient, and efficiency for rotor-inlet relative Mach numbers up to 1.1.

NACA RM E53G27

INVESTIGATION OF TURBINES FOR DRIVING SUPERSONIC COMPRESSORS. V - DESIGN AND PERFORMANCE OF THIRD CONFIGURATION WITH NONTWISTED ROTOR BLADES. Warren J. Whitney, Warner L. Stewart, and Daniel E. Monroe. September 1953. 23p. diagrs., photos., tab. (NACA RM E53G27)

The design and the performance of a turbine rotor with nontwisted blades designed to drive a supersonic compressor are presented herein. The performance results obtained with this turbine are compared with the results of a free-vortex turbine which was designed for this application, and both the design and off-design performance of the two turbines were very nearly the same. From the comparison of the performance results, it was demonstarted that employing a nontwisted rotor blade velocity distribution for this application enabled the use of a high degree of blade-chord taper as a stress-reduction device without any apparent deterioration of overall turbine performance.

NACA RM E53J13

PUMPING AND THRUST CHARACTERISTICS OF SEVERAL DIVERGENT COOLING-AIR EJECTORS AND COMPARISON OF PERFORMANCE WITH CONICAL AND CYLINDRICAL EJECTORS. S. C. Huntley and Herbert Yanowitz. January 1954. 42p. diagrs. (NACA RM E53J13)

An investigation was made of the performance of four divergent ejectors having shroud-exit to primary-nozzle-exit diameter ratios of 1.2 and 1.3 with minimum-shroud to primary-nozzle-exit diameter

DECLASSIFIED NACA RESEARCH REPORTS

ratios of 1.1 and 1.2, respectively, and spacing ratios of 0.87 and 1.6. A comparison of the performance of conical, cylindrical, and divergent ejectors showed that on the basis of similar design variables (exit-diameter ratio and spacing ratio) each configuration has merit. At an exit-diameter ratio of 1.2 and spacing ratios of 0.9 and 1.6, the divergent ejector had the highest thrust at zero secondary flow. With corrected weight-flow ratios of 0.03 and 0.07, the divergent ejector had the highest thrust at low primary pressure ratios, while the cylindrical ejector had the highest thrust at high primary pressure ratios. The range of primary pressure ratio over which the cylindrical ejector was advantageous in thrust increased for both the higher corrected weight-flow ratio and the larger spacing ratio. The conical ejector, however, can pump a given corrected weight flow over a wider range of primary pressure ratio but at the expense of a relatively low ejector thrust. The divergent ejector had the smallest range of primary pressure ratio for a given corrected weight-flow ratio. The possibility of obtaining ejector thrust performance from a simple one-dimensional equation by using a measurement of wall pressure distribution was illustrated.

NACA RM E53J28

PRELIMINARY INVESTIGATION OF PERFORMANCE OF VARIABLE-THROAT EXTENDED-PLUG-TYPE NOZZLES OVER WIDE RANGE OF NOZZLE PRESSURE RATIOS. Carl C. Ciepluch, H. George Krull, and Fred W. Steffen. February 1954. 35p. diagrs., photos., tab. (NACA RM E53J28)

As part of an overall program for the experimental investigation of large-scale jet nozzles, a preliminary evaluation of the internal performance characteristics of several variable-throat extended-plug-type nozzles was obtained over a range of nozzle pressure ratios from 2 to 15 with nozzle throat-area variations as great as 2:1. The extended-plug nozzle attained peak thrust coefficients as high as those which have been attained with fixed-geometry convergent-divergent nozzles. The thrust coefficients of the extended-plug nozzles were relatively insensitive to both nozzle pressure ratio and throat area over the range investigated. The lack of sensitivity of thrust coefficient to nozzle pressure ratio and throat area was due primarily to the absence of severe decreases in thrust coefficient, which are normally observed at low nozzle pressure ratios for convergent-divergent nozzles because of overexpansion. For choked flow, the flow coefficients of the extended-plug nozzles varied from 0.95 to 0.997. A ratio of the outer-shell exit area to nozzle throat area was found to be an important variable affecting nozzle performance. Most of the configurations reported herein showed a small decrease in thrust coefficient at low nozzle pressure ratios; however, it is believed that this characteristic can be nearly eliminated by proper nozzle design.

NACA RM E53L23a

GENERAL CONSIDERATIONS OF MACH NUMBER EFFECTS ON COMPRESSOR-BLADE DESIGN. John F. Klapproth. April 1954. 24p. diagrs., photos. (NACA RM E53L23a)

A very approximate design method was used to obtain a qualitative effect of Mach number on blade shape for a prescribed velocity distribution. Experimental performance of ratios having blades similar to those obtained using the approximate design procedure shows rotor efficiencies above 70 percent for rotor tip Mach numbers up to 1.4. A critical factor influencing the performance appeared to be the rotor tip diffusion.

NACA RM E55I20

DESIGN CONSIDERATIONS OF A CONDENSING SYSTEM FOR VAPORIZED MAGNESIUM. Walter R. Witzke, George M. Prok, and Thomas A. Keller. November 1955. 19p. diagrs., photos., tabs. (NACA RM E55I20)

The effect of the design characteristics of various condensing chambers on magnesium buildup at the chamber inlet was investigated. The condensing chambers are used in the vapor-condensation process for making magnesium slurries. A complete description of the various chamber designs and the procedure used in testing the chambers is given. The results are evaluated on the basis of clogging and total magnesium distilled per run. Orifice design was also considered.

NACA RM E56D10a

ESTIMATION OF SPECIFIC SURFACE OF FINELY DIVIDED MAGNESIUM. Murray L. Pinns. August 1956. 28p. diagrs., tabs. (NACA RM E56D10a)

A preliminary investigation into the estimation of the specific surface of finely divided magnesium from the adsorption of cetyl alcohol from hydrocarbon solution indicated that the method may be satisfactory. Average particle diameters calculated from estimates made on atomized and vapor-process magnesium agreed within a factor of 2 with electron-microscope observations. A correlation was found between adsorption and the minimums in plots of Brookfield viscosity and yield value against cetyl-alcohol concentration. Magnesium slurries containing up to 5 percent cetyl alcohol were centrifuged, and the quantities of cetyl alcohol adsorbed were determined from the interfacial tensions between the supernatant liquids and water. Suggestions were made for improving the procedure.

NACA RM L50J03

AN INVESTIGATION OF THE LONGITUDINAL CHARACTERISTICS OF THE X-3 CONFIGURATION USING ROCKET-PROPELLED MODELS. PRELIMINARY RESULTS AT MACH NUMBERS FROM 0.65 TO 1.25. Jesse L. Mitchell and Robert F. Peck. December 1, 1950. 30p. diagrs., photos. (NACA RM L50J03)

A rocket-propelled model of the X-3 has been flown using the disturbance technique to obtain longitudinal stability, control, trim, and drag data in the Mach number range from 0.65 to 1.25. The model is statically and dynamically stable but had slightly nonlinear lift and pitching-moment characteristics at subsonic speeds. The drag rise begins at about 0.9 Mach number and amounts to 0.042 increase in drag coefficient at zero lift. The transonic trim change is of small magnitude at the test center of gravity (-15 percent of the mean aerodynamic chord).

NACA RM L51J15

TESTS AT MACH NUMBER 1.62 OF A SERIES OF MISSILE CONFIGURATIONS HAVING TANDEM CRUCIFORM LIFTING SURFACES. Carl E. Grigsby. January 1952. 106p. diagrs., tabs. (NACA RM L51J15)

An investigation was made in the Langley 9-inch supersonic tunnel of a series of missile configurations having low-aspect-ratio tandem lifting surfaces of nearly equal span. Breakdown tests were made on a total of 10 configurations comprising combinations of five wings and six tails. For each configuration these tests included: two longitudinal wing locations relative to the tail, two roll angles for both the wing and the tail (0° and 45°), and the in-line and interdigitated cases for each roll angle. All tests were made at a Mach number of 1.62 and a Reynolds number of 0.348×10^6 per inch. The angle-of-attack range was from -5° to 15°. The lift, drag, and pitching-moment data, center-of-pressure locations, and tail-lift efficiency factors are presented without analyses.

NACA RM L52D18a

LARGE-SCALE FLIGHT MEASUREMENTS OF ZERO-LIFT DRAG OF 10 WING-BODY CONFIGURATIONS AT MACH NUMBERS FROM 0.8 TO 1.6. John D. Morrow and Robert L. Nelson. January 1953. 53p. diagrs., photo., tabs. (NACA RM L52D18a)

Measurements of zero-lift drag were made at high Reynolds numbers and at Mach numbers from 0.8 to 1.6 of 10 wing-body configurations having straight, swept, and triangular wing plan forms and thickness ratios from 3 to 12 percent. The wings were mounted on bodies of fineness ratio 10. Of several wing-body configurations having straight, swept, and delta wings of equal area, a 3-percent-thick, 60° delta wing had the least zero-lift drag at supersonic speeds. At transonic speeds, however, a 5.6-percent-thick swept wing had the least drag. At low supersonic speeds the maximum lift-drag ratios for all models were between 7 and 9.5. Changing the section of a straight wing from a hexagonal section to an NACA 65A004.5 section resulted in a 23-percent reduction in zero-lift drag coefficient at transonic speeds. At higher speeds the drag difference decreased, and it was zero at $M = 1.4$. Doubling the thickness of the 3-percent-thick, 60° delta wing added roughly 40 percent to the configuration drag and 60 percent to the wing drag at zero lift. Differences in body profile shape had a large effect on the interference drag of a wing-body combination at transonic speeds, but were of little significance at subsonic and supersonic speeds for the specific bodies studied in this investigation. The base pressures on the bodies of the present configurations indicate base drags of very small magnitude. The pressures were affected by the size and shape of the wings mounted on the body.

NACA RM L52F23

PRELIMINARY FREE-FLIGHT INVESTIGATION OF THE ZERO-LIFT DRAG PENALTIES OF SEVERAL MISSILE NOSE SHAPES FOR INFRARED SEEKING DEVICES. Robert O. Piland. December 1952. 22p. diagrs., photos. (NACA RM L52F23)

The results of a preliminary investigation to develop a nose shape suitable for housing an infrared seeker are presented. The zero-lift drag characteristics of a missile-like body with various unconventional nose shapes were obtained through a range of Mach numbers from 0.8 to 1.8 and Reynolds numbers, based on body length, from 20×10^6 to 70×10^6, respectively, by using rocket-propelled free-flight models. Results of the test indicate that at supersonic speeds about 70 percent of the drag penalty incurred by using spherical-tip nose shapes may be eliminated by using nose shapes which will still allow the seeker to function.

NACA RM L52J08

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF BODIES MOUNTED FROM THE WING OF AN UNSWEPT-WING-FUSELAGE MODEL, INCLUDING MEASUREMENTS OF BODY LOADS. H. Norman Silvers and Thomas J. King, Jr. November 1952. 37p. diagrs., photos., tabs. (NACA RM L52J08)

Ogive-cylinder bodies of fineness ratio 9.34 were tested in the Langley high-speed 7- by 10-foot tunnel with two lengths of pylon support at 0.33 semispan, one length of pylon support at 0.96 semispan, and mounted directly to the wing tips of a wing-fuselage model which had an unswept wing of aspect ratio 4, taper ratio 0.6, and NACA 65A006 airfoil sections. The pylon support members were unswept and had NACA 64A010 airfoil sections. Forces and moments in pitch of the combined model and bodies were measured in addition to six-component force and moment measurements of the bodies in the presence of the model over a Mach number range extending from 0.50 to 0.91.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L52J20

PRELIMINARY INVESTIGATION OF THE EFFECTS OF INLET ASYMMETRY ON THE PERFORMANCE OF CONVERGING-DIVERGING DIFFUSERS AT TRANSONIC SPEEDS. John S. Dennard and William J. Nelson. November 1952. 30p. diagrs., photos., tab. (NACA RM L52J20)

The effects of inclining the plane of the inlet on the performance of several converging-diverging diffusers at zero angle of attack have been investigated at Mach numbers from 0.30 to 1.15 and at 1.41. It was found that converging-diverging diffusers designed for $M = 1.41$ with appreciable constant-area throat lengths operated without abrupt changes in performance over the entire speed and mass-flow ranges. It was also shown that spillage at slightly subcritical flow rates may be localized by inclining the plane of the inlet. At slightly subcritical flow rates a small reduction in pressure loss was obtained at the highest test speed, $M = 1.41$, by inclining the inlet plane 45°. At speeds up to $M = 1.15$ the inclined inlets had about the same pressure recovery as the unskewed inlets.

NACA RM L52J24a

FLIGHT INVESTIGATION OF THE ZERO-LIFT DRAG OF TWO RAM-JET MISSILE CONFIGURATIONS AT MACH NUMBERS FROM 1.00 TO 1.89. Clarence A. Brown, Jr., and Walter E. Bressette. March 1953. 24p. diagrs., photos. (NACA RM L52J24a)

Flight tests were conducted to determine the zero-lift external drag of an underslung single-inlet ram-jet missile configuration and a two-dimensional twin-inlet missile configuration. The external-drag coefficient for the underslung single-inlet ram jet varied smoothly with Mach number whereas the external-drag coefficient of the two-dimensional twin-inlet ram jet had a gradual rise to a peak value at a Mach number of 1.37 and then varied smoothly with increased Mach number.

NACA RM L52J27

EFFECTS OF THE SPANWISE, CHORDWISE, AND VERTICAL LOCATION OF AN EXTERNAL STORE ON THE AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK TAPERED WING OF ASPECT RATIO 4 AT MACH NUMBERS OF 1.41, 1.62, AND 1.96. Carl R. Jacobsen. January 1953. 31p. diagrs., photo. (NACA RM L52J27)

An investigation has been made in the Langley 9- by 12-inch supersonic blowdown tunnel to determine the effects of external-store location on the lift, drag, and pitching-moment characteristics of a tapered 45° sweptback wing of aspect ratio 4 at Mach numbers of 1.41, 1.62, and 1.96. The chordwise and vertical location of a store having a Douglas Aircraft Company, Inc., store shape of fineness ratio 8.58 was systematically varied over the outer 60 percent of the wing semispan. For a wing area of 600 square feet, the store would have sufficient volume to contain about 400 gallons of fuel.

NACA RM L52L12

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF BODY INDENTATION, AS SPECIFIED BY THE TRANSONIC DRAG-RISE RULE, ON THE AERODYNAMIC CHARACTERISTICS AND FLOW PHENOMENA OF A 45° SWEPTBACK-WING-BODY COMBINATION. Harold L. Robinson. February 1953. 33p. diagrs., photos., tab. (NACA RM L52L12)

The aerodynamic characteristics of a sweptback-wing-body configuration having the body indented according to the transonic drag-rise rule as given in NACA RM L52H08 have been compared with those for a configuration with the body cylindrical at the wing-body juncture. This investigation indicated that body indentation reduced the drag coefficient at transonic speeds up to a lift coefficient of 0.4 by the same amount as at zero lift.

NACA RM L52L23

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF BODY INDENTATION, AS SPECIFIED BY THE TRANSONIC DRAG-RISE RULE, ON THE AERODYNAMIC CHARACTERISTICS AND FLOW PHENOMENA OF AN UNSWEPT-WING-BODY COMBINATION. Claude V. Williams. January 1953. 38p. diagrs., photos., tabs. (NACA RM L52L23)

The aerodynamic characteristics and flow phenomena of an unswept-wing-body configuration, having the body indented in the region of the wing-body juncture according to the transonic drag-rise rule, have been compared in a transonic wind-tunnel investigation with the characteristics of a similar configuration that was cylindrical in the region of the wing-body juncture. This investigation indicated that body indentation significantly reduced the transonic drag at lift coefficients up to 0.4.

NACA RM L52L26b

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF ASPECT RATIO, SPANWISE VARIATIONS IN SECTION THICKNESS RATIO, AND A BODY INDENTATION ON THE AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK WING-BODY COMBINATION. Melvin M. Carmel. January 1953. 44p. diagrs., tab. (NACA RM L52L26b)

Results are presented which show that the favorable effects of increasing the aspect ratio from 4 to 6 at subsonic speeds more than offset the adverse effects of moderately increasing the thickness ratio of the inboard sections of a wing. At the supersonic test Mach numbers, the effects were approximately equal. Large favorable effects at Mach numbers above approximately 0.90 can be obtained by indenting the body of a wing-body combination with thickened inboard wing sections. The favorable effect becomes increasingly greater with increases in Mach number and lift coefficient.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53D14a

INVESTIGATION OF THE DRAG OF BLUNT-NOSED BODIES OF REVOLUTION IN FREE FLIGHT AT MACH NUMBERS FROM 0.6 TO 2.3. Harvey A. Wallskog and Roger G. Hart. June 1953. 28p. diagrs., photos., tab. (NACA RM L53D14a)

The effects on total drag coefficient of some nose-shape modifications which could provide suitable housings for guidance systems are presented. Data from rocket-propelled, fin-stabilized bodies of revolution were measured in free flight up to a Mach number of 2.3 and Reynolds numbers, based on body length, as high as 80×10^6. Small degrees of spherical bluntness on parabolic noses produced a small decrease in drag at low supersonic Mach numbers. It was shown that some modifications to a blunt-nosed shape may produce appreciable reductions in total drag. The increase in drag coefficient for a spherical nose of given size is shown to be greater when the round nose replaces the tip of a higher fineness-ratio parabolic nose. Estimated drag-coefficient increments due to spherical bluntness are compared with experimental results.

NACA RM L53E25

THE EFFECT OF NACELLE COMBINATIONS AND SIZE ON THE ZERO-LIFT DRAG OF A 45° SWEPTBACK WING AND BODY CONFIGURATION AS DETERMINED BY FREE-FLIGHT TESTS AT MACH NUMBERS BETWEEN 0.8 AND 1.3. Sherwood Hoffman and William B. Pepper, Jr. June 1953. 22p. diagrs., photos., tabs. (NACA RM L53E25)

The effect on zero-lift drag of increasing the size and number of nacelles on a 45° sweptback wing and body combination has been determined by free-flight tests of rocket-propelled models through a range of Mach numbers varying from 0.8 to 1.3 and Reynolds numbers from 4×10^6 to 7×10^6 based on the wing mean aerodynamic chord. The drag rises of the models were found to be in general agreement with the concepts of the transonic drag-rise rule.

NACA RM L53F05a

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF BODY INDENTATION ON THE AERODYNAMIC CHARACTERISTICS OF AN APPROXIMATE-DELTA-WING-BODY CONFIGURATION, AND A COMPARISON WITH A WING OF REVERSED PLAN FORM. Claude V. Williams. August 1953. 36p. diagrs., photos., tabs. (NACA RM L53F05a)

The aerodynamic characteristics and flow phenomena of an approximate-delta-wing–body configuration, having the body indented according to the transonic drag-rise rule, have been compared in a transonic wind-tunnel investigation with the characteristics of a similar configuration that was cylindrical in the region of the wing-body juncture. This investigation indicated that body indentation significantly reduced the transonic drag rise at lift coefficients up to 0.4, and increased the maximum lift-drag ratio. A comparison with the results of a previous investigation indicated that reversal of wing plan form had little effect on the drag characteristics at Mach numbers near 1.0.

NACA RM L53G02

INVESTIGATION OF AN AXIAL-FLOW COMPRESSOR ROTOR HAVING NACA HIGH-SPEED BLADE SECTIONS (A_2I_{8b} SERIES) AT MEAN RADIUS RELATIVE INLET MACH NUMBERS UP TO 1.13. Melvyn Savage, John R. Erwin, and Robert P. Whitley. November 1953. 43p. diagrs., photos., tab. (NACA RM L53G02)

A high-pressure-ratio, axial-flow-compressor rotor, bladed with NACA A_2I_{8b}-series blade sections, was tested over a range of rotor inlet Mach numbers at the mean radius from 0.63 to 1.13. The general results indicate that efficient high-pressure-ratio transonic rotors can be designed for operation at mean radius inlet Mach numbers up to approximately 0.87 using low-speed cascade data; for operation at higher inlet Mach numbers, low-speed cascade data must be supplemented with a more detailed examination of the transonic flow field. The use of low-speed cascade data for determining design angles of attack was quite effective in that peak efficiency and design angle-of-attack efficiency were coincident at 0.96 for inlet Mach numbers up to 0.87. Above 0.87 while design angle-of-attack efficiency decreased rapidly, peak efficiency gradually decreased to 0.90 at a Mach number of 0.96 where total pressure ratio was 1.555. The shift in peak efficiency to higher than design angles of attack is explained by examination of the effects of angle-of-attack variation on the severity of the pressure gradients of blade upper and lower surfaces.

NACA RM L53I25b

SOME CONSIDERATIONS CONCERNING INLETS AND DUCTED BODIES AT MACH NUMBERS FROM 0.8 TO 2.0. Richard I. Sears. November 1953. 17p. diagrs. (NACA RM L53I25b)

Recently obtained data for the drag and pressure recovery of various nose, scoop, and wing root inlets at Mach numbers 0.8 to 2.0 are presented. The discussion points out some of the large differences that can exist in the drag and pressure recovery of good and not-so-good configuration.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53J08a

CONTROL HINGE-MOMENT AND EFFECTIVENESS CHARACTERISTICS OF SEVERAL INTERCHANGEABLE TIP CONTROLS ON A 60° DELTA WING AT MACH NUMBERS OF 1.41, 1.62, AND 1.96. Odell A. Morris. November 1953. 33p. diagrs., photo., tab. (NACA RM L53J08a)

An experimental investigation has been made to supplement information obtained previously with tip controls on a 60° delta wing. Control hinge moments and effectiveness characteristics were determined with and without fences at the wing-control juncture for several tip controls having different amounts of leading- or trailing-edge sweep. The effects of wing skew were also examined. Tests were made over an angle-of-attack range of ±12° and for control deflections up to 20° at Mach numbers 1.41, 1.62, and 1.96 and Reynolds numbers of 2.4×10^6, 2.25×10^6, and 2.0×10^6, respectively.

NACA RM L53J20a

AN INVESTIGATION OF THE TRANSONIC AREA RULE BY FLIGHT TESTS OF A SWEPTBACK WING ON A CYLINDRICAL BODY WITH AND WITHOUT BODY INDENTATION BETWEEN MACH NUMBERS 0.9 AND 1.8. Sherwood Hoffman. December 1953. 24p. diagrs., photos., tabs. (NACA RM L53J20a)

The results of an investigation of the transonic area rule by flight tests of a sweptback-wing—cylindrical-body configuration with and without a fuselage indentation and of their equivalent bodies of revolution are presented over a continuous Mach number range from 0.9 to 1.8. The drag rise of the flight models was found to be in general agreement with the concepts of the transonic area rule and with the results of tests of similar models in the Langley 8-foot transonic tunnel. The fuselage indentation produced an undesirable increase in the drag of the configuration above Mach number 1.18.

NACA RM L53J22a

INVESTIGATION AT TRANSONIC SPEEDS OF AERODYNAMIC CHARACTERISTICS OF A SEMIELLIPTICAL AIR INLET IN THE ROOT OF A 45° SWEPTBACK WING. Robert R. Howell and Charles D. Trescot, Jr. December 1953. 39p. diagrs., photos., tabs. (NACA RM L53J22a)

An investigation has been made in the Langley transonic blowdown tunnel to determine the changes in lift, drag, and pitching-moment characteristics due to a semielliptical-shaped air inlet installed in the root of a 45° sweptback wing and to study the internal-flow characteristics of the inlet. The tests were conducted for a Mach number range from 0.63 to 1.41 at a Reynolds number of approximately 6.5×10^6. The measurements included pressures at the inlet and at an assumed compressor face station, and the lift, drag, and pitching moments for ranges of angle of attack and inlet mass-flow ratio from 0° to 9.6° and 0.3 to 0.86, respectively. A maximum total pressure recovery of 97 percent free-stream total pressure was obtained. The external drag increment due to the inlet installation was generally small for the test Mach number range.

NACA RM L53J27a

A STUDY OF THE USE OF LEADING-EDGE NOTCHES AS A MEANS FOR IMPROVING THE LOW-SPEED PITCHING-MOMENT CHARACTERISTICS OF A THIN 45° SWEPT WING OF ASPECT RATIO 4. Joseph Weil and William D. Morrison, Jr. December 1953. 17p. diagrs. (NACA RM L53J27a)

In an effort to develop a simple but effective means of controlling the stall progression of swept wings, a low-speed investigation has been undertaken primarily to determine the effectiveness of leading-edge notches. The investigation included considerations of notch size, location, and shape, as well as combined effects of notch—chord-extension and notch-fence arrangements. The wing used for the study had 45° quarter-chord sweep, aspect ratio 4, taper ratio 0.3, and 65A006 airfoil sections streamwise.

NACA RM L53J30

PRELIMINARY INVESTIGATION OF THE TOTAL-PRESSURE-RECOVERY CHARACTERISTICS OF A SYMMETRIC AND AN ASYMMETRIC NOSE INLET OVER A WIDE RANGE OF ANGLE OF ATTACK AT SUPERSONIC MACH NUMBERS. Howard S. Carter and Charles F. Merlet. December 1953. 27p. diagrs., photo. (NACA RM L53J30)

A preliminary investigation was made of the total-pressure-recovery characteristics of a symmetric nose inlet at a Mach number M of 1.42 and of an asymmetric nose inlet at M = 1.42 and 1.84. The symmetric inlet maintained a maximum recovery of 0.95 for all mass-flow ratios tested between angles of attack of -6° and 6°. At M = 1.42 and 1.84, the asymmetric inlet was relatively insensitive to positive angle of attack through 30°, but encountered severe separation losses at negative angles of attack. The maximum recoveries attained were 0.97 at M = 1.42 and 0.80 at M = 1.84.

NACA RM L53K17

TRANSONIC DRAG MEASUREMENTS OF EIGHT BODY-NOSE SHAPES. William E. Stoney, Jr. February 1954. 14p. diagrs., photos. (NACA RM L53K17)

Zero-lift drag data were obtained on a series of eight fin-stabilized bodies having fineness-ratio-3 noses and differing only in nose shape. The models were launched from the Langley helium gun (at the testing station at Wallops Island, Va.) and data were obtained for Mach numbers from 0.8 to 1.25 with corresponding Reynolds numbers (based on body length) of 8×10^6 to 15×10^6. The results were compared with theoretical calculations and with wind-tunnel measurements. Lowest transonic drag values were obtained with nose shapes defined by the Von Kármán optimum and by a parabola with its vertex at the nose tip.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53L07

LOW-SPEED CASCADE TESTS OF TWO 45° SWEPT COMPRESSOR BLADES WITH CONSTANT SPANWISE LOADING. Loren A. Beatty, Melvyn Savage, and James C. Emery. March 1954. 65p. diagrs., photos., tab. (NACA RM L53L07)

A cascade investigation of two 45° swept blades was conducted in the low-speed cascade tunnels at the Langley Laboratory. In this investigation, a series of tests was conducted in the 5-inch cascade tunnel at a solidity of 1.00 and an inlet-air angle of 60° on a 2.5-inch chord blade whose camber shape and twist distribution were calculated by the method of NACA TN 1350 to obtain a uniform spanwise loading. In addition, a blade of 5-inch chord, linear twist distribution, and NACA 65-(10A2I8b)10 blade section was tested in the 10-inch cascade tunnel at inlet-air angles of 30°, 45°, and 60° at a solidity of 1.00 and at an inlet-air angle of 45° at solidities of 1.25 and 1.50.

NACA RM L53L21

FLIGHT INVESTIGATION OF ENGINE NACELLES AND WING VERTICAL POSITION ON THE DRAG OF A DELTA-WING AIRPLANE CONFIGURATION FROM MACH NUMBER 0.8 TO 2.0. Joseph H. Judd. March 1954. 39p. diagrs., photos., tabs. (NACA RM L53L21)

Flight tests from Mach numbers 0.8 to 2.0 and Reynolds numbers, based on the wing mean aerodynamic chord, from 5.8×10^6 to 22.8×10^6 were made for a 60° delta wing (NACA 65A003 airfoil section) mounted in midwing and high-wing positions on a modified transonic body with ducted ram-jet type nacelles at 66 percent of the wing semispan. The high-wing configurations, with and without nacelles, had greater drag coefficients than corresponding midwing configurations.

NACA RM L54A08

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF BODY INDENTATION FOR BOATTAIL AND CYLINDRICAL AFTERBODY SHAPES ON THE AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT-WING—BODY COMBINATION. Thomas C. Kelly. March 1954. 22p. diagrs., tab. (NACA RM L54A08)

An investigation has been conducted in the Langley 8-foot transonic tunnel to study the effects of body indentation, as specified by the area rule, and afterbody shape on the aerodynamic characteristics of an unswept-wing—body combination. Results indicate that the transonic drag rise for a wing-body combination may be markedly reduced by indentation. Also, the transonic drag rise for a cylindrical afterbody configuration was less severe than that for a boattail configuration, while the use of body indentation with both configurations resulted in nearly the same proportional reductions of the transonic drag rise at a Mach number of 1.0. Data are presented at angles of attack from 0° to 8° and at Mach numbers from 0.80 to 1.15.

NACA RM L54A15

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF TAPER RATIO, BODY INDENTATION, FIXED TRANSITION, AND AFTERBODY SHAPE ON THE AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK WING-BODY COMBINATION. Francis G. Morgan, Jr., and Melvin M. Carmel. March 1954. 37p. diagrs., tab. (NACA RM L54A15)

This paper presents the aerodynamic characteristics of wing-body combinations having wings of aspect ratio 4 and 45° sweepback. Comparisons are made to determine the effects of taper ratio, body indentation, fixed transition, and afterbody shape. The tests covered a Mach number range from 0.80 to 1.15, angles of attack from 0° to 12°, and Reynolds numbers varying from 1.80×10^6 to 2.00×10^6 based on the mean aerodynamic chord of the wings.

NACA RM L54A27

ZERO-LIFT DRAG OF SEVERAL CONICAL AND BLUNT NOSE SHAPES OBTAINED IN FREE FLIGHT AT MACH NUMBERS OF 0.7 TO 1.3. Robert O. Piland and Leonard W. Putland. March 1954. 14p. diagrs., photos., tab. (NACA RM L54A27)

The zero-lift drag characteristics of seven nose shapes on a slender body of revolution have been determined in free flight between Mach numbers of 0.7 and 1.3 corresponding to Reynolds numbers, based on body length, of 6×10^6 and 11×10^6, respectively. The nose shapes tested consisted of a spherical segment, a flat face with a sharp shoulder, a flat face with a rounded shoulder, 30° and 40° total-angle cones, and a spherical segment with each of two different-length spikes projecting upstream from the center of the nose.

NACA RM L54A29

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF BODY INDENTATION ON THE AERODYNAMIC CHARACTERISTICS OF A SEMI-ELLIPTICAL SWEPTBACK WING-ROOT INLET CONFIGURATION. Arvid L. Keith, Jr. March 1954. 22p. diagrs., photos., tabs. (NACA RM L54A29)

The drag characteristics of a semielliptical shaped sweptback wing-root inlet configuration with fuselage indented to eliminate the effective area added by the inlet installation have been compared with those of a basic wing-body combination and a sweptback wing-root inlet configuration without indentation at Mach numbers from 0.65 to 1.4. The comparisons show that indentation eliminated the small increment in transonic drag coefficient caused by installation of the inlet in the root of the basic wing-body combination. For the major part of the supersonic Mach

DECLASSIFIED NACA RESEARCH REPORTS

number range investigated, the indented inlet configuration had lower drag than either the basic configurations or the plain inlet configuration and indications were that indentation would be effective to Mach numbers somewhat higher than the test limit. Discussion of some aspects of the application of the transonic area rule to air inlet configurations in general is included.

NACA RM L54B02

THE EFFECT OF NACELLE LOCATION ON THE ZERO-LIFT DRAGS OF 45° SWEPTBACK WING-BODY CONFIGURATIONS HAVING BOATTAIL AND CYLINDRICAL AFTERBODIES AS DETERMINED BY FLIGHT TESTS AT TRANSONIC SPEEDS. Sherwood Hoffman and Austin L. Wolff. March 1954. 29p. diagrs., photos., tabs. (NACA RM L54B02)

The effects of nacelle location on the zero-lift drags of 45° sweptback wing-body combinations having boattail and cylindrical afterbodies have been determined by flight tests of rocket-propelled models through a range of Mach number from 0.8 to 1.25 and Reynolds number from 4×10^6 to 7×10^6 based on the wing mean aerodynamic chord. The drag rises of the models were found to be in qualitative agreement with the concepts of the transonic area rule near Mach number 1.0.

NACA RM L54B10

AN ANALYSIS OF PRESSURE STUDIES AND EXPERIMENTAL AND THEORETICAL DOWNWASH AND SIDEWASH BEHIND FIVE POINTED-TIP WINGS AT SUPERSONIC SPEEDS. William B. Boatright. April 1954. ii, 119p. diagrs., photos. (NACA RM L54B10)

The results of flow angle and pressure surveys throughout cross-flow planes at 1.5, 3, and 4 chords behind pointed-tip wings are presented. Three triangular wings of 50°, 63°, and 72° leading-edge sweep angle were surveyed at free-stream Mach numbers of 1.62 and 2.41. Also flow surveys were conducted behind the 50° triangular wing reversed and behind a pointed-tip wing having a sweptback leading edge and a sweptforward trailing edge (both 50°) at Mach number 1.62. In the analysis of the data, especial attention is focused on the assessment of the various theoretical methods for predicting the flow angle at wing angles of attack where the deflection and distortion of the vortex sheet become important.

NACA RM L54E11

THE EFFECT OF CANOPY LOCATION ON THE AERODYNAMIC CHARACTERISTICS OF A SWEPTBACK WING-BODY CONFIGURATION AT TRANSONIC SPEEDS. Harold L. Robinson. June 1954. 14p. diagrs., photo. (NACA RM L54E11)

Transonic wind-tunnel tests of three configurations - basic wing-body combination, a canopy placed on the body so as to fill the concave portion of the wing-body area distribution curve (design location), and a configuration having the canopy placed 0.0614 of the body length forward of this design location - indicated that significant drag reductions can be achieved by proper canopy location.

NACA RM L54H13a

A FLIGHT INVESTIGATION OF THE TRANSONIC AREA RULE FOR A 52.5° SWEPTBACK WING-BODY CONFIGURATION AT MACH NUMBERS BETWEEN 0.8 AND 1.6. Sherwood Hoffman. November 1954. 25p. diagrs., photos., tab. (NACA RM L54H13a)

The results of an investigation of the transonic area rule by zero-lift rocket-model tests of models of a 52.5° sweptback wing-body configuration with and without a fuselage indentation and of equivalent bodies of revolution are presented through a range of Mach number from 0.8 to 1.6 and Reynolds number from 4×10^6 to 12×10^6, based on wing mean aerodynamic chord. The wing had a taper ratio of 0.2, aspect ratio 3.0, and an NACA 65A004 airfoil section in the free-stream direction. The drag rises of the configurations are studied according to the concepts of the area rule at transonic and supersonic speeds. The Mach number 1.0 indentation lowered the drag rise between Mach numbers 0.9 and 1.35, and increased the pressure drag above Mach number 1.35.

NACA RM L54H30

EFFECT ON TRANSONIC AND SUPERSONIC DRAG OF FUSELAGE GLOVES DESIGNED TO GIVE A SMOOTH OVERALL AREA DISTRIBUTION TO A SWEPT-WING—BODY COMBINATION. James Rudyard Hall. November 1954. 10p. diagrs., photos. (NACA RM L54H30)

A free-flight investigation into the effect of fuselage gloves, or local increases in volume, designed to improve the overall longitudinal area distribution of a swept-wing—body combination revealed that a reduction of about 20 percent in maximum pressure drag was obtained. The drag reduction effected by the use of gloves decreased with increasing Mach number, becoming zero at a Mach number of about 1.35, the limit of the experiments.

NACA RM L54I01a

A METHOD FOR DESIGNING LOW-DRAG NOSE-INLET—BODY COMBINATIONS FOR OPERATION AT MODERATE SUPERSONIC SPEEDS. Robert R. Howell. November 1954. 29p. diagrs., photos., tab. (NACA RM L54I01a)

The results of an experimental investigation in the Mach number range between 0.8 and 1.4 and a related analytical study indicate that pressure-drag equivalence can be obtained between an axially symmetric nose-inlet—body combination and its equivalent body according to the transonic area rule at inlet mass-flow ratios at least as low as 0.7. It was also demonstrated that the equivalent-body concept is an effective method for obtaining low-drag nose-inlet—body combinations for operation at moderate supersonic speeds.

NACA RM L54I21

THE EFFECT OF SOME SURFACE ROUGHNESS ELEMENTS ON THE DRAG OF A BODY OF REVOLUTION AT SUPERSONIC SPEEDS. Russell N. Hopko. November 1954. 14p. diagrs., photos., tab. (NACA RM L54I21)

The effects of some rivets, butt joints, and lap joints on the drag of a body of revolution at zero lift at supersonic Mach numbers to 2.1 have been obtained in free flight with rocket-propelled models. The butt joints tested showed no significant effects on the drag. Rivets and lap joints increased the drag of the smooth-body configuration, the forward-facing lap joints contributing the greatest increases.

NACA RM L54J20

PRELIMINARY LOW-SPEED WIND-TUNNEL INVESTIGATION OF SOME ASPECTS OF THE AERODYNAMIC PROBLEMS ASSOCIATED WITH MISSILES CARRIED EXTERNALLY IN POSITIONS NEAR AIRPLANE WINGS. William J. Alford, Jr., H. Norman Silvers, and Thomas J. King, Jr. December 1954. 30p. diagrs., photos., tab. (NACA RM L54J20)

A low-speed wind-tunnel investigation was made of some aspects of the aerodynamic problems associated with the use of missiles carried externally near airplane wings. Flow-field surveys were made at the one-half semispan station of a 45° sweptback-wing-fuselage combination. Force and moment measurements were obtained on a model of a typical air-to-air guided missile when traversing the measured flow fields. A comparison of estimated and experimental missile aerodynamic characteristics as affected by the flow fields is presented.

NACA RM L54J29a

JET EFFECTS ON LONGITUDINAL TRIM OF AN AIRPLANE CONFIGURATION MEASURED AT MACH NUMBERS BETWEEN 1.2 AND 1.8. Robert F. Peck. January 1955. 17p. diagrs., photos. (NACA RM L54J29a)

During free-flight tests of a model with a horizontal tail mounted just behind and above a propulsive-jet exit but outside the blast cone, strong jet-induced effects on longitudinal trim were measured. Positive tail loads are believed to have resulted from the formation of a shock wave near or impinging on the tail and originating near the intersection of the external flow and the jet boundary.

NACA RM L54K12a

EFFECTS OF BODY INDENTATION ON THE DRAG CHARACTERISTICS OF A DELTA-WING–BODY COMBINATION AT TRANSONIC SPEEDS. Dewey E. Wornom and Robert S. Osborne. January 1955. 32p. diagrs., photos., tabs. (NACA RM L54K12a)

Wing-body combinations employing a 60° delta wing and three bodies of revolution were tested at Mach numbers from 0.60 to 1.14. Force and moment characteristics of configurations employing the basic body and bodies with indentation based on the transonic and supersonic area-rule concept are presented. Body indentations designed for Mach numbers of 1.0 and 1.4 were both effective in reducing the transonic zero-lift drag rise.

NACA RM L54K16

EXPERIMENTAL INVESTIGATION OF AN AXIAL-FLOW SUPERSONIC COMPRESSOR HAVING SHARP LEADING-EDGE BLADES WITH AN 8-PERCENT MEAN THICKNESS-CHORD RATIO AND OF THE EFFECT OF A LEADING-EDGE RADIUS. Theodore J. Goldberg. February 1955. 33p. diagrs., photo. (NACA RM L54K16)

Details are presented of the results of tests in Freon-12 gas of an axial-flow supersonic compressor having sharp leading-edge blades with an 8-percent mean thickness-chord ratio. Tests were made for a range of tip speed from 485 to 815 fps in Freon-12 which corresponds to a range from 1,050 to 1,760 fps in air. At the design speed of 730 fps (1,600 fps in air) with guide vanes, the rotor produced a total-pressure ratio of 2.06 with an efficiency of 78.6 percent at an equivalent weight flow of 51.2 lb/sec of Freon-12. Without guide vanes, the values were 1.96, 74.5, and 52, respectively. Effects of rounding the leading edge on rotor performance are also presented.

NACA RM L54L02a

ANALYSIS OF AERODYNAMIC BLADE-LOADING-LIMIT PARAMETERS FOR NACA 65-$(C_{l_0}A_{10})10$ COMPRESSOR-BLADE SECTIONS AT LOW SPEEDS. Melvyn Savage. April 1955. 32p. diagrs. (NACA RM L54L02a)

A simple cascade loading-limit parameter for incompressible axial-flow compressor-blade elements was developed from an analysis of previously published incompressible cascade and rotor data on NACA 65-$(C_{l_0}A_{10})10$ compressor-blade sections. Analysis of the data indicated that there was good correlation between loss coefficient and loading-limit parameter with very little effect of inlet angle and solidity over a wide range of inlet-angle, angle-of-attack, and solidity conditions. The loading parameter appeared to be effective in predicting the onset of rotor stall for the rotor conditions investigated.

DECLASSIFIED NACA RESEARCH REPORTS

A comparison between the loading-limit parameter presented herein with the diffusion factor of NACA RM E53D01 was made by utilizing the incompressible rotor data over the wide range of inlet-angle and solidity conditions for which data were available.

NACA RM L54L28

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF TAPER RATIO AND BODY INDENTATION ON THE AERODYNAMIC LOADING CHARACTERISTICS OF A 45° SWEPTBACK WING IN THE PRESENCE OF A BODY. James B. Delano and John P. Mugler, Jr. April 1955. 53p. diagrs., photos., tab. (NACA RM L54L28)

This paper presents the aerodynamic loading characteristics of wings having an aspect ratio of 4, 45° sweepback of the 0.25-chord line, and taper ratios of 0.3 and 0.6 in the presence of unindented and indented bodies. Comparisons are made to show the effect of taper ratio and body indentation on the aerodynamic loading characteristics. The tests covered a Mach number range from 0.6 to 1.2 and an angle-of-attack range from 0° to 20° at a Reynolds number of approximately 2.0×10^6 based on the average chord for the wings.

NACA RM L54L31

SOME STUDIES OF AXISYMMETRIC FREE JETS EXHAUSTING FROM SONIC AND SUPERSONIC NOZZLES INTO STILL AIR AND INTO SUPERSONIC STREAMS. Eugene S. Love and Carl E. Grigsby. May 1955. ii, 178p. diagrs., photos., tabs. (NACA RM L54L31)

Results are presented of some experimental and theoretical studies made of axisymmetric jets exhausting from sonic and supersonic nozzles into still air and into supersonic streams with a view toward current problems associated with propulsive jets and the investigation of these problems.

NACA RM L55F03

EFFECT OF WING SIZE AND AMOUNT OF INDENTATION ON APPLICABILITY OF TRANSONIC AREA RULE TO SWEPT-WING CONFIGURATIONS. James Rudyard Hall. July 1956. 33p. diagrs., photos., tabs. (NACA RM L55F03)

A systematic free-flight investigation was made to help define the range of applicability of the transonic area rule to swept-wing configurations. The reduction of pressure drag obtainable from partial indentation is approximately proportional to the amount of indentation employed up to a Mach number of 1.3. Generally, for unindented swept-wing configurations it is possible to obtain the pressure drag within 10 percent by applying a ratio of pressure drag measured for the present configurations to the measured pressure drag of the equivalent body of the configuration. In two cases it was possible to approximate the drag of a swept-wing configuration with an equivalent body incorporating a more severe wing projection than a normal projection. Wing-fuselage interference drag did not vary appreciably for the three wing sizes tested for unindented bodies.

NACA RM L55G11

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC LOADING CHARACTERISTICS OF A 60° DELTA WING IN THE PRESENCE OF A BODY WITH AND WITHOUT INDENTATION. John P. Mugler, Jr. September 1955. 30p. diagrs., photos., tab. (NACA RM L55G11)

This paper presents force and moment test results showing the aerodynamic loading characteristics of a 60° delta wing in the presence of a basic (unindented) body and the same body when indented in accordance with the transonic-area-rule concept. The wing had 60° sweepback of the leading edge, an aspect ratio of 2.31, a taper ratio of 0, and NACA 65A003 airfoil sections parallel to the model plane of symmetry. Comparisons are made to show the effect of body indentation on the loading characteristics. The tests covered a Mach number range from 0.6 to 1.2 and an angle-of-attack range from 0° to 20° at a Reynolds number of about 3.6×10^6 based on the wing mean aerodynamic chord.

NACA RM L55J12

SOME EFFECTS OF SWEEP AND THICKNESS ON THE EXPERIMENTAL DOWNWASH CHARACTERISTICS AT TRANSONIC SPEEDS OF A SERIES OF HIGHLY TAPERED WINGS WITH AN ASPECT RATIO OF 3. TRANSONIC-BUMP METHOD. Albert G. Few, Jr. February 1956. 65p. diagrs., photo. (NACA RM L55J12)

The present paper presents experimental results of some effects of sweep and thickness on the transonic downwash and wake characteristics of a series of highly tapered wings with an aspect ratio of 3. The tests covered a Mach number range from 0.60 to 1.18 and employed the transonic-bump-test technique. Reynolds numbers ranged from about 0.78×10^6 to 0.93×10^6 and angles of attack from -2° to about 24°. The downwash and dynamic pressure were measured for a range of vertical heights at one spanwise station, and for a given wing plan form, at only one longitudinal station.

NACA RM L55J13

PRELIMINARY FREE-FLIGHT STUDY OF THE DRAG AND STABILITY OF A SERIES OF SHORT-SPAN MISSILES AT MACH NUMBERS FROM 0.9 TO 1.3. James Rudyard Hall. February 1956. 14p. diagrs., photo. (NACA RM L55J13)

A preliminary free-flight study has been made of the drag and stability of a series of missile configurations employing 80°, 85°, and 90° of fin leading-edge sweep. Increasing the fin sweep reduced the drag markedly. The configurations employing 80° and 85° of fin sweep were stable with the center of gravity as far rearward as at least 54 and 52 percent of the body length, respectively. The configuration employing 90° of fin sweep was marginally stable with the center of gravity at 43 percent of the body length. The Reynolds number of the tests varied from 4×10^6 at a Mach number of 0.9 to 9×10^6 at a Mach number of 1.3.

NACA RM L55J14

INITIAL INCLINATION OF THE MIXING BOUNDARY SEPARATING AN EXHAUSTING SUPERSONIC JET FROM A SUPERSONIC AMBIENT STREAM. Eugene S. Love. January 1956. 30p. diagrs. (NACA RM L55J14)

Calculations have been made of the initial inclination of the mixing boundary separating an exhausting supersonic jet from an external supersonic stream as a function of jet static-pressure ratio. The calculations are based on a ratio of specific heats of 7/5 for the external stream and 9/7 for the jet. The results are presented in curve form and cover, in terms of the conditions immediately ahead of the jet exit, the following range of variables: boattail and nozzle divergence angles from 0° to 20°, external-stream Mach numbers from 1.2 to 3.0, jet Mach numbers from 1.0 to 3.0, and jet static-pressure ratios within the approximate inviscid limits for supersonic flow, except at the higher jet and stream Mach numbers where the calculations were terminated somewhat short of these limits.

NACA RM L55J20

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC LOADING CHARACTERISTICS OF A HIGHLY TAPERED UNSWEPT WING IN THE PRESENCE OF A BODY WITH AND WITHOUT INDENTATION. Joseph D. Brooks. February 1956. 30p. diagrs., photos., tab. (NACA RM L55J20)

An investigation of the aerodynamic loading characteristics and the effects of body indentation on the wing loads of an unswept wing with an aspect ratio of 2.67, a taper ratio of 0.2, and 4-percent-thick circular-arc airfoil sections measured parallel to the plane of symmetry was conducted in the Langley 8-foot transonic pressure tunnel. An internal strain-gage balance was used to measure wing loads independently of the body load. The tests covered a Mach number range from 0.6 to 1.2 and an angle-of-attack range from 0° to 20° at a Reynolds number of about 2.7×10^6.

NACA RM L55J25

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF SOME EFFECTS OF FUSELAGE CROSS-SECTION SHAPE AND WING HEIGHT ON THE STATIC LONGITUDINAL AND LATERAL STABILITY CHARACTERISTICS OF A MODEL HAVING A 45° SWEPT WING. Thomas J. King, Jr. February 1956. 61p. diagrs., photo. (NACA RM L55J25)

This paper presents results of an investigation to determine the effects of fuselage cross-section shape on the high subsonic speed longitudinal and lateral stability characteristics of low- and high-wing—fuselage combinations. The wing had an aspect ratio of 4, taper ratio of 0.3, sweep of 45° of the quarter-chord line, and an NACA 65A006 airfoil section. The tests covered a Reynolds number range from 2.5×10^6 to 3.0×10^6, a Mach number range from 0.8 to 0.92, and an angle-of-attack range from -3° to 24°.

NACA RM L56A05

USE OF SHADOWGRAPH TECHNIQUE IN THE ANALYSIS OF THE PERFORMANCE OF TWO SUPERSONIC AXIAL-FLOW COMPRESSOR ROTORS OPERATING OVER A MEAN RADIUS RELATIVE INLET MACH NUMBER RANGE OF 0.85 TO 1.7. Theodore J. Goldberg and James R. Sterrett. April 1956. 48p. diagrs., photos. (NACA RM L56A05)

Shadowgraphs of the flow patterns through the blade passage and ahead of a compressor rotor were obtained by shining parallel light rays approximately radially onto the rotor hub and upstream inner ring which were painted white to serve as a screen. The visible flow patterns were used in conjunction with measured data to analyze the performance of two axial-flow supersonic compressors operating over a mean radius relative inlet Mach number range of 0.85 to 1.7 in Freon-12. This simple shadowgraph technique allowed a qualitative study of the starting mechanism, shock position and movement, and separation associated with shock boundary-layer interaction. A comparison with previous results of these two rotors obtained in another test stand indicates the possibility of test-stand and tip-clearance effects on rotor performance.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L56I07

EXPERIMENTAL INVESTIGATION OF THE AERODYNAMIC LOADING ON A HELICOPTER ROTOR BLADE IN FORWARD FLIGHT. John P. Rabbott, Jr., and Gary B. Churchill. October 1956. 65p. diagrs., photos., tabs. (NACA RM L56I07)

Chordwise and spanwise aerodynamic loading distributions have been measured on one blade of a two-blade teetering rotor for a tip-speed-ratio range of 0.08 to 0.29. These data and the variation of section and total blade loading with azimuth are presented. Also determined are the harmonic content and phase angles of loading for six harmonics of rotor speed. The harmonic content of the measured data is much greater than a uniform-inflow theory would predict. The nondimensional spanwise loading is indicated to be relatively constant with disk loading and tip-speed ratio.

NACA RM L57A03

INVESTIGATION OF THE EFFECT OF VELOCITY DIAGRAM ON INLET TOTAL-PRESSURE DISTORTIONS THROUGH SINGLE-STAGE SUBSONIC AXIAL-FLOW COMPRESSORS. George C. Ashby, Jr. April 1957. 21p. diagrs., photo. (NACA RM L57A03)

A preliminary theoretical and experimental investigation of the effect of velocity diagram on inlet total-pressure distortions through single-stage subsonic axial-flow compressors has been conducted. The wake of a 1/4-inch-diameter rod was measured upstream of a rotor. By using the measured upstream wake and a derived equation for incompressible flow, the wake downstream of the rotor was estimated and compared with the measured downstream wake for several velocity diagrams. From the results of the investigation, optimum velocity diagrams for eliminating total-pressure distortions across single-stage axial-flow compressors were determined. It was determined that the derived equation will estimate the distortion downstream of the rotor with reasonable accuracy for distortions which are large enough circumferentially to alter the static-pressure field in the blade passage.

NACA RM L57E03

LOW-SPEED CASCADE INVESTIGATION OF THIN LOW-CAMBER NACA 65-SERIES BLADE SECTIONS AT HIGH INLET ANGLES. James C. Emery. June 1957. 93p. diagrs., tab. (NACA RM L57E03)

An investigation of 6-percent-thick NACA 65-series compressor blade sections has been conducted in a two-dimensional porous-wall cascade tunnel. Blades cambered to have isolated airfoil lift coefficients of 0, 0.4, 0.8, and 1.2 were tested over the usable angle-of-attack range at inlet-air angles of 60°, 70°, and 75° and solidities of 0.75, 1.00, and 1.50. A few tests were made at a solidity of 2.00. The results of this investigation indicate a continuous variation of blade-section performance as the major cascade parameters (camber, solidity, and inlet angle) change and provide design information for a range of compressor operation that heretofore has been supplied by extrapolation.

TRANSPORT OF RADIOACTIVITY BY LIQUID SODIUM IN A STAINLESS STEEL CIRCULATION SYSTEM. D. Fieno and D. Bogart. March 2, 1955. 17p. diagrs., photos., tab. (NACA RM E54K03)

Radioactivity transport experiments were conducted in a stainless-steel system in which liquid sodium was circulated over an activated stainless-steel insert section. The system consisted of a sealed toroid loop partly filled with sodium. Circulation of the sodium was induced by an oscillatory motion of the toroid in an apparatus developed at the NACA Lewis Laboratory. Periodic measurements of radioactivity at sections of the toroid loop established the growth of transported activity in the loop.

Research Abstracts and Reclassification Notice

DEC - 6 1957
BATTELLE MEMORIAL INSTITUTE

NO. 122 DECEMBER 3, 1957

SPECIAL NOTICE

All NACA publications that were issued under the following series designations are now declassified:

NACA ACR (Advance Confidential Report)
NACA ARR (Advance Restricted Report)
NACA CB (Confidential Bulletin)
NACA RB (Restricted Bulletin)
NACA MR (Memorandum Report)

None of these series designations is currently used; the last publications designated by them were issued in 1947.

All NACA Research Memorandums with 1946 code numbers (such as E6B12) are now declassified.

The declassification of each publication in these groups has been previously announced. The present announcement is made for the benefit of those who may not have access to all of the individual announcements.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1309

AERODYNAMIC CHARACTERISTICS AT HIGH SPEEDS OF RELATED FULL-SCALE PROPELLERS HAVING DIFFERENT BLADE-SECTION CAMBERS. Julian D. Maynard and Leland B. Salters, Jr. 1957. ii, 24p. diagrs., photos., tab. (NACA Rept. 1309. Supersedes RM L8E06)

Comparisons are made of results obtained in wind-tunnel tests of related full-scale propellers over a range of blade angles from 20° to 55° at airspeeds up to 500 miles per hour to evaluate the combined effects of blade-section camber and compressibility on propeller aerodynamic characteristics.

NACA RM E57G11

ACCELERATION IN FIGHTER-AIRPLANE CRASHES. Loren W. Acker, Dugald O. Black, and Jacob C. Moser. November 1957. 78p. diagrs., photos. (NACA RM E57G11)

Full-scale crashes were conducted with FH-1 jet fighter airplanes under circumstances approximating those observed in the military service. These crashes simulated unflared landings at impact angles of 18°, 22°, and 27°, a ground cart wheel, and a ground loop. The magnitude, duration, and direction of the crash accelerations were measured on the airplane structure and on an anthropomorphic dummy installed in the cockpit. The accelerations measured are compared with existing data on human tolerance to the sudden loads that occur in crashes to see whether the human tolerance had been exceeded.

THEORETICAL ROCKET PERFORMANCE OF JP-4 FUEL WITH SEVERAL FLUORINE-OXYGEN MIXTURES ASSUMING FROZEN COMPOSITION. Sanford Gordon and Kenneth S. Drellishak. November 1957. 62p. diagrs., tabs. (NACA RM E57G16a)

Data were calculated for a chamber pressure of 600 pounds per square inch absolute, fluorine in oxidant from 0 to 100 percent, pressure ratios of 1 to 1500, and a range of equivalence ratios. Parameters included are specific impulse, combustion and exit temperatures, molecular weight, characteristic velocity, coefficient of thrust, area ratio, specific heat, isentropic exponent, viscosity, thermal conductivity, and combustion composition.

NACA TN 4046

A COMPARATIVE ANALYSIS OF THE PERFORMANCE OF LONG-RANGE HYPERVELOCITY VEHICLES. Alfred J. Eggers, Jr., H. Julian Allen, and Stanford E. Neice. October 1957. (i), 66p. diagrs. (NACA TN 4046. Supersedes RM A54L10)

A simplified analysis is made of the motion and aerodynamic heating of long-range ballistic-, skip-, and glide-type vehicles. The ballistic vehicle appears relatively attractive because convective heat transfer can be reduced by using blunt shapes. The glide vehicle appears attractive because it has a relatively efficient trajectory, and the possibility of substantial radiative cooling. These vehicles compare favorably, in the sense of the Brequet range equation, to the supersonic airplane for very long-range flight.

NACA TN 4047

A STUDY OF THE MOTION AND AERODYNAMIC HEATING OF MISSILES ENTERING THE EARTH'S ATMOSPHERE AT HIGH SUPERSONIC SPEEDS. H. Julian Allen and A. J. Eggers, Jr. October 1957. 61p. diagrs. (NACA TN 4047. Supersedes RM A53D28)

A simplified analysis of the velocity and deceleration history of missiles entering the earth's atmosphere at high supersonic speeds is presented. The results of this motion analysis are employed to indicate means available to the designer for minimizing aerodynamic heating. The heating problem considered involves not only the total heat transferred to a missile by convection, but also the maximum average and local time rates of convective heat transfer.

NACA TN 4048

MOTION OF A BALLISTIC MISSILE ANGULARLY MISALINED WITH THE FLIGHT PATH UPON ENTERING THE ATMOSPHERE AND ITS EFFECT UPON AERODYNAMIC HEATING, AERODYNAMIC LOADS, AND MISS DISTANCE. H. Julian Allen. October 1957. 66p. diagrs., tabs. (NACA TN 4048. Supersedes RM A56F15)

An analysis is given of the oscillating motion of a ballistic missile which upon entering the atmosphere is angularly misalined with respect to the flight path. The history of the motion for some example missiles is discussed from the point of the effect of the motion on the aerodynamic heating and loading. The miss distance at the target due to misalinement and to small accidental trim angles is treated. The stability problem is also discussed for the case where the missile is tumbling prior to atmospheric entry.

NACA TN 4087

DROP-SIZE DISTRIBUTION FOR CROSSCURRENT BREAKUP OF LIQUID JETS IN AIRSTREAMS. Robert D. Ingebo and Hampton H. Foster. October 1957. 36p. diagrs., photos. tabs. (NACA TN 4087)

Photographic and sampling techniques were combined to obtain drop-size data for ranges of injector, liquid, and airstream variables. The following empirical expression correlated the ratio of volume-median diameter D_{30} to orifice diameter D_O with Weber-Reynolds number ratio $D_{30}/D_O = 3.9(We/Re)^{0.25}$ where $We = \sigma/\rho_S D_O V_S^2$, $Re = D_O V_S/\nu$, σ and ν are surface tension and kinematic viscosity, respectively, of the liquid; and V_S and ρ_S are free-stream velocity and density, respectively, of the air. A drop-size-distribution equation based on maximum observed drop diameter and Weber-Reynolds number ratio was also derived.

$$\frac{dR}{dD} = 10^6\left(\frac{We}{Re}\right)^{0.24} \frac{D^5}{D_{max}^6} e^{-22.3(We/Re)^{0.04}D/D_{max}}$$

NACA TN 4097

INVESTIGATION OF SOME MECHANICAL PROPERTIES OF THERMENOL COMPRESSOR BLADES. Donald F. Johnson. October 1957. 14p. diagrs., photo. (NACA TN 4097)

A series of tests were made comparing the mechanical properties of similar compressor blades of AISI type 403 stainless steel and thermenol. Eighth-stage J47 and J65 compressor blades of each material were tested. Modulus of elasticity, modulus of rigidity, and damping were slightly lower for thermenol. However, thermenol showed better resistance to corrosion by sea water, and the thermenol blades proved equal or superior to the stainless-steel blades in fatigue strength.

NACA TN 4124

EFFECT OF GROUND PROXIMITY ON THE AERODYNAMIC CHARACTERISTICS OF A FOUR-ENGINE VERTICAL-TAKE-OFF-AND-LANDING TRANSPORT-AIRPLANE MODEL WITH TILTING WING AND PROPELLERS. William A. Newsom, Jr. October 1957. 15p. diagrs., photo., tab. (NACA TN 4124)

An investigation was conducted on an airplane model with the wing at an angle of incidence of 90° for a range of heights of the model above the ground and included force tests and tuft studies of the flow field caused by the propeller slipstream. The results indicate that, when the model was hovering near the ground, there was a strong upwash in the plane of symmetry which caused both an increase in lift because of the up load on the fuselage and an increase in the nose-down pitching moment because the rear part of the fuselage was longer than the front part.

NACA TN 4129

ANALYSIS OF OPERATIONAL AIRLINE DATA TO SHOW THE EFFECTS OF AIRBORNE WEATHER RADAR ON THE GUST LOADS AND OPERATING PRACTICES OF TWIN-ENGINE SHORT-HAUL TRANSPORT AIRPLANES. Martin R. Copp and Walter G. Walker. November 1957. 18p. diagrs., tabs. (NACA TN 4129)

Airspeed, altitude, and acceleration data were obtained from transports flown by one airline before and subsequent to the installation of airborne weather radar. A comparison of the results indicated that the magnitudes of the largest gust velocities and gust accelerations experienced for a given number of flight miles during radar operations were approximately 25 percent less than those experienced before the radar equipment was installed.

NACA TN 4130

NACA 65-SERIES COMPRESSOR ROTOR PERFORMANCE WITH VARYING ANNULUS-AREA RATIO, SOLIDITY, BLADE ANGLE, AND REYNOLDS NUMBER AND COMPARISON WITH CASCADE RESULTS. Wallace M. Schulze, John R. Erwin, and George C. Ashby, Jr. October 1957. 62p. diagrs., photos., tab. (NACA TN 4130. Supersedes RM L52L17)

An axial-flow compressor rotor was tested at low speed and without guide vanes or stators in a 28-inch test compressor. The rotor was designed for a free-vortex type blade loading using NACA 65-series 10-percent-thick airfoil sections. In these tests, the effects of changes of blade-setting angle, annulus-area ratio, solidity, and Reynolds number on rotor performance were determined for a range of quantity flows. Rotor data are compared with estimations based on uncorrected and corrected cascade data.

NACA TN 4132

FATIGUE INVESTIGATION OF FULL-SCALE TRANSPORT-AIRPLANE WINGS. VARIABLE-AMPLITUDE TESTS WITH A GUST-LOADS SPECTRUM. Richard E. Whaley. November 1957. 43p. diagrs., photos., tabs. (NACA TN 4132)

Crack-initiation areas, frequency of occurrence of cracks, crack propagation, lifetime to crack initiation of all cracks, lifetime to final failure, and spread in lifetime are investigated and compared with results from constant-amplitude tests on similar wings. Information on X-ray techniques to determine the presence of cracks in hidden elements is also included.

NACA TN 4143

DEVELOPMENT OF A PISTON-COMPRESSOR TYPE LIGHT-GAS GUN FOR THE LAUNCHING OF FREE-FLIGHT MODELS AT HIGH VELOCITY. A. C. Charters, B. Pat Denardo, and Vernon J. Rossow. November 1957. (i), 95p. diagrs., photos., tabs. (NACA TN 4143. Supersedes RM A55G11)

A light-gas gun has been developed at the Ames Aeronautical Laboratory to launch small models for aerodynamic tests. The design of the gun and the analysis of its performance are presented. The results of the initial firing trials are discussed. The firing trials showed good agreement between measured and predicted velocities and pressures and a velocity of 15,400 ft/sec was reached. It is concluded that the gun is a satisfactory launcher for high-velocity free-flight tests.

NACA TN 4156

EFFECT OF INITIAL MIXTURE-TEMPERATURE ON BURNING VELOCITY OF HYDROGEN-AIR MIXTURES WITH PREHEATING AND SIMULATED PREBURNING. Sheldon Heimel. October 1957. 23p. diagrs., tabs. (NACA TN 4156)

Laminar burning velocities were determined in the temperature range 300° to 700° K from schlieren photographs of open flames. The temperature was raised in two ways: (1) by preheating of the hydrogen-air mixtures and (2) by simulated adiabatic preburning of part of the hydrogen in air at 300° K so that initial temperatures of 600° and 700° K would be attained for the resulting mixtures of hydrogen, air, water vapor, and nitrogen. The temperature dependence of burning velocity was determined for both preheated and preburned mixtures. With 29.6 and 45.0 percent hydrogen (original mixture), mole-for-mole substitution of nitrogen for water vapor in the preburning experiments caused no discernible change in burning velocity.

NACA TN 4162

STUDY OF SOME BURNER CROSS-SECTION CHANGES THAT INCREASE SPACE-HEATING RATES. Donald R. Boldman and Perry L. Blackshear, Jr. November 1957. 38p. diagrs., photos., tab. (NACA TN 4162)

A two-dimensional glass-walled combustor fed with a homogeneous combustible mixture was used to study the effect of area blockage on heat release. The blockage at a single V-gutter flame holder was varied from 12.5 to 75 percent with negligible effect on combustion efficiency. When a small flame holder was used and a 62.5-percent restriction introduced downstream, the heat-release rate underwent a three- to fourfold increase. Some effects of downstream blockage shapes are given.

NACA TN 4167

A RAPID METHOD FOR PREDICTING ATTACHED-SHOCK SHAPE. Eugene S. Love and Ronald H. Long. October 1957. 34p. diagrs., tab. (NACA TN 4167)

A method is presented for the rapid prediction of the shape of attached shocks emanating from smoothly contoured axisymmetric and two-dimensional nose shapes. From a practical viewpoint the accuracy of the method is comparable to that of the method of characteristics.

NACA TN 4169

ATMOSPHERIC TEMPERATURE OBSERVATIONS TO 100,000 FEET FOR SEVERAL CLIMATOLOGICAL REGIONS OF THE NORTHERN HEMISPHERE. H. B. Tolefson. November 1957. 26p. diagr., tab. (NACA TN 4169)

Radiosonde measurements of upper-air temperatures taken over a 5-year period at nine stations in the northern hemisphere are summarized in tabular form in order to provide information on the temperatures likely to be encountered during airplane and missile operations up to 100,000 feet. The results indicate that the scatter in the temperatures about the mean generally decreased with increasing altitude from the tropopause to 100,000 feet. Little, if any, effect of location upon the temperature was apparent for altitudes above about 90,000 feet.

NACA TN 4171

SOME GROUND MEASUREMENTS OF THE FORCES APPLIED BY PILOTS TO A SIDE-LOCATED AIRCRAFT CONTROLLER. Roy F. Brissenden. November 1957. 17p. diagrs., photos., tab. (NACA TN 4171)

Ground tests have been made to determine pilots' force capabilities on a proposed side-located aircraft controller. In addition to maximum force capabilities, pilots participating in the tests indicated forces that they considered desirable for operation of the controller. A neutral position and a range of deflections and forces are suggested.

NACA TN 4174

WIND-TUNNEL INVESTIGATION OF THE STATIC LATERAL STABILITY CHARACTERISTICS OF WING-FUSELAGE COMBINATIONS AT HIGH SUBSONIC SPEEDS. TAPER-RATIO SERIES. James W. Wiggins and Paul G. Fournier. October 1957. 25p. diagrs., photos. (NACA TN 4174. Supersedes RM L53B25a)

This paper presents the aerodynamic characteristics in sideslip of wing-fuselage combinations. The wings have a sweep angle of 45° at the quarter-chord line, aspect ratio of 4, taper ratios of 0.3, 0.6, and 1.0, and an NACA 65A006 airfoil section. The tests covered a Mach number range from 0.4 to 0.95, a Reynolds number range from 1.7×10^6 to 3.2×10^6, and an angle-of-attack range from -3° to 24°.

NACA TN 4175

INVESTIGATION OF DEFLECTORS AS GUST ALLEVIATORS ON A 0.09-SCALE MODEL OF THE BELL X-5 AIRPLANE WITH VARIOUS WING SWEEP ANGLES FROM 20° TO 60° AT MACH NUMBERS FROM 0.40 TO 0.90. Delwin R. Croom and Jarrett K. Huffman. November 1957. 28p. diagrs. (NACA TN 4175)

An investigation has been made in the Langley high-speed 7- by 10-foot tunnel to determine the effectiveness of deflectors as gust alleviators on a 0.09-scale model of the Bell X-5 research airplane with wing sweep angles from 20° to 60°. Results of this study have indicated that a deflector arrangement can be used as a gust-alleviation device on swept wings.

SOME METHODS OF EVALUATING IMPERFECT GAS EFFECTS IN AERODYNAMIC PROBLEMS. G. A. Bird. January 1957. 31p. diagrs. RAE Tech. Note Aero 2488. (Ask for N-50049*)

Simple numerical and graphical procedures are described for the calculation of the imperfect gas effects on the properties of steady and unsteady one-dimensional isentropic flows, the Prandtl-Meyer expansion round a corner and normal and oblique shock waves. The fundamental equations of each type of flow have been put into a form in which they may be solved using the published tables of the equilibrium properties of gases. Both thermal and caloric imperfections have been taken into account but relaxation time effects have been neglected. Numerical examples are given for each type of flow although the main emphasis has been placed on the methods rather than on the results. These basic methods have been used to calculate the magnitude of the imperfect gas effects on a number of specific aerodynamic problems which have been considered in detail.

METHODS FOR DETERMINING THE WAVE DRAG OF NON-LIFTING WING-BODY COMBINATIONS. L. M. Sheppard. April 1957. 39p. diagrs. RAE Aero 2590. (Ask for N-50128*)

The area rule, moment of area rule, and transfer rule methods for estimating the wave drag of wing-body combinations are discussed. It is pointed out that the moment of area rule and the transfer rule are different forms of the area rule, and that the transfer rule expresses the interference wave drag in a simple form. The existing methods of wave drag estimation are restricted to combinations with bodies having continuous surface slope and here an extension to combinations with bodies having discontinuous surface slope is given. This paper is concerned with the theoretical methods and their associated numerical techniques and no numerical results or particular applications are presented.

FACTORS AFFECTING THE THERMAL STABILITY OF POLYESTER GLASS-FIBRE LAMINATES. B. A. Blythe and W. W. Wright. April 1957. 20p. diagrs., tabs. RAE Tech. Note Chem. 1306.
(Ask for N-50132*)

The effects of variation of glass cloth, glass-cloth treatment, and initiator for the polymerization reaction on the flexural strength at elevated temperatures of polyester glass-fiber laminates have been studied. The strengths of high- and low-alkali glass-cloth laminates were comparable. The use of treated glass cloths resulted in improved initial strength and strength retention with time; this was especially true of the Garan finish. Variation of the initiator used for the curing reaction, although resulting in a wide variation of the flexural strength values after particular times at temperature, appeared to have little effect on the characteristics of the thermal breakdown. The variations in flexural strength of laminates made using 10 heat-resistant laminating resins were determined with time at elevated temperature. Very good results were obtained with a phenolic resin.

Royal Aircraft Establishment (Gt. Brit.)
BRIEF LANDING TRIALS USING THE FLUSH LIGHTING PATTERN IN THE RUNWAY AT THE ROYAL NETHERLANDS AIR FORCE STATION AT SOESTERBERG. E. N. Hooton. March 1957. 20p. diagrs. RAE Tech. Note. BL. 45.
(Ask for N-50144*)

At the Royal Netherlands Air Force airfield at Soesterberg a center line and cross bar approach lighting pattern is installed within the runway flush with the runway surface. Brief flight tests have been made using Varsity and Devon aircraft to examine the visual guidance provided by this approach pattern during final flare and landing. Although, in detail, far from ideal for such a purpose, the provision of a pattern within the runway was considered to be a great improvement on runway edge lighting by three of the four pilots who took part in the tests. The results in general confirm ground simulator tests and indicate certain elements essential to any visual guidance system for landing.

Battelle Memorial Institute. THE EFFECT OF VARIATIONS IN MELTING AND CASTING PROCEDURE ON THE STRUCTURE AND HIGH-TEMPERATURE PROPERTIES OF CAST X-40 ALLOY. E. E. Fletcher, H. J. Hucek, A. R. Elsea, and G. K. Manning. January 16, 1957. (iii), 59p. diagrs., photos., tabs. Battelle Memorial Inst. (Ask for N-55837*)

Melting and pouring atmospheres, such as vacuum, which lowered the nitrogen content of X-40 alloy below some minimum value (approximately 0.05 to 0.07 percent) markedly reduced the high-temperature strength of the alloy. The loss of other elements during melting had a relatively minor effect on the properties. Variations in pouring temperature over the range of 2650° to 2850° F had little effect on the properties. Of the three mold preheat temperatures studied (300°, 1600°, and 1900° F), castings made in 1900° F molds yielded the best and most consistent high-temperature properties. No consistent relationship between microstructure and high-temperature properties was observed; however, there were indications that castings with an intermediate grain size were stronger than those with either extremely coarse or fine grain sizes. The high-temperature bend test was found to be unsuitable as a screening test for stress-rupture properties, but it appeared to be useful for evaluating deformation or creep characteristics.

Polytechnic Institute of Brooklyn. ON SOME EXACT SOLUTIONS OF LAMINAR MIXING IN THE PRESENCE OF AXIAL PRESSURE GRADIENTS. Luigi G. Napolitano. December 1955. 22p. Polytechnic Inst. of Brooklyn. PIBAL Report 302. (Ask for N-55839*)

The well-known power and exponential velocity distributions in the Stewartson plane are shown to still yield similar solutions in the case of compressible mixing provided an additional requirement, concerning the Mach number distributions of the two streams, is satisfied. Analysis of the corresponding incompressible problem shows that no similar solutions are possible except for the simplest case of zero pressure gradient. For the mixing of two uniform streams the ordinary differential equation giving the similar solutions is shown to reduce to the Blasius equation in both the compressible and the incompressible cases. Consequently with this approach the time-consuming iteration process which arises in the previously given methods of analysis is eliminated. The possibility of a rapid investigation of temperature effect on wake characteristics is stressed.

INVESTIGATION OF A TRAILING-EDGE PADDLE-CONTROL SURFACE ON A TRIANGULAR WING OF ASPECT RATIO 2 AT SUBSONIC AND SUPERSONIC SPEEDS. Louis H. Ball. February 1954. 18p. diagrs., tab. (NACA RM A53K20)

This report presents the results of an experimental investigation of external airfoils known as paddle-control surfaces as the longitudinal control device on a triangular wing of aspect ratio 2. The lift, drag, pitching moment, and hinge moment were obtained for Mach numbers of 0.60, 0.80, 0.90, 1.20, 1.30, 1.50, 1.70, and 1.90 at a constant Reynolds number of 3.0×10^6, for angles of attack from about -4° to 18° and for paddle-control deflections from approximately 4° to -16°.

NACA RM A54K09

LONGITUDINAL STABILITY CHARACTERISTICS AT MACH NUMBERS UP TO 0.92 OF A WING-BODY-TAIL COMBINATION HAVING A WING WITH 45° OF SWEEPBACK AND A TAIL IN VARIOUS VERTICAL POSITIONS. Jack D. Stephenson, Angelo Bandettini, and Ralph Selan. January 1955. 64p. diagrs., photos., tabs. (NACA RM A54K09)

Data are presented showing lift, drag, and static longitudinal stability characteristics of a wing-body-tail combination having a 45° sweptback wing with an aspect ratio of 5.5. Lowering the horizontal tail to the wing chord plane extended resulted in significant improvements in the stability of the model both with an unmodified wing and with fences or chord extensions on the wing.

NACA RM E9K29

ANALYTICAL AND EXPERIMENTAL INVESTIGATION OF THRUST AUGMENTATION OF AXIAL- AND CENTRIFUGAL-COMPRESSOR TURBOJET ENGINES BY INJECTION OF WATER AND ALCOHOL IN COMBUSTION CHAMBERS. David S. Gabriel, Harry W. Dowman, and William L. Jones. April 13, 1950. 43p. diagrs., photo. (NACA RM E9K29)

Thrust augmentation by injection of water and water-alcohol mixtures into combustion chambers was investigated at sea-level zero-ram conditions on axial- and centrifugal-flow turbojet engines. Thrust augmentation, compressor characteristics, fuel flow, and turbine-outlet-temperature distributions are presented for various injection rates and water-alcohol mixtures. A method of computing thrust augmentation produced by injection into the combustion chambers is presented. Computed augmented-thrust ratios were within 1 percent of the experimental results. Water injection into the centrifugal-flow engine produced little thrust augmentation.

EXPERIMENTAL INVESTIGATION OF TAIL-PIPE-BURNER DESIGN VARIABLES. W. A. Fleming, E. William Conrad, and A. W. Young. March 5, 1951. 75p. diagrs., photos., tab. (NACA RM E50K22)

The results of several experimental tail-pipe-burner investigations at the NACA Lewis Laboratory are summarized to indicate the effects of tail-pipe-burner design variables on performance and operating characteristics. Most of the configurations were operated over wide ranges of altitudes and flight Mach numbers. The data indicate the effect of changes in principal design variables, such as flame-holder type, burner length, burner diameter, and fuel distribution on performance, and indicate the features of a tail-pipe burner that will operate with high combustion efficiency up to an altitude of approximately 50,000 feet.

NACA RM E51A25

INVESTIGATION OF ALTITUDE IGNITION, ACCELERATION AND STEADY-STATE OPERATION WITH SINGLE COMBUSTOR OF J47 TURBOJET ENGINE. William P. Cook and Helmut F. Butze. March 5, 1951. 35p. diagrs., photo., tab. (NACA RM E51A25)

Satisfactory ignition was obtained with a J47 single combustor up to and including an altitude of 40,000 feet at conditions simulating equilibrium windmilling of the engine at flight speed of 400 miles per hour. At 30,000 feet, excess temperature rise available for combustion was limited by the ability of the combustor to provide temperature rise, whereas at high engine speeds the maximum allowable turbine-inlet temperature became the restricting factor.

DECLASSIFIED NACA RESEARCH REPORTS

Altitude operational limits increased from about 51,500 feet at 55-percent rated speed to about 64,500 feet at 85-percent rated speed. Combustion efficiencies varied from 39.0 to 92.6 percent.

#NACA RM E51K06, by Prince and Wintler

NACA RM E51K20

ANALYTICAL AND EXPERIMENTAL INVESTIGATION OF INLET-ENGINE MATCHING FOR TURBOJET-POWERED AIRCRAFT AT MACH NUMBERS UP TO 2.0. Carl F. Schueller and Fred T. Esenwein. February 1952. 31p. diagrs., photos. (NACA RM E51K20)

An analysis of inlet-turbojet-engine matching for a range of Mach numbers up to 2.0 indicates large performance penalties when fixed-geometry inlets are used. Use of variable-geometry inlets, however, nearly eliminates these penalties. The analysis was confirmed experimentally by investigating at Mach numbers of 0, 0.63, and 1.5 to 2.0 two single oblique-shock-type inlets of different compression-ramp angles, which simulated a variable-geometry configuration. The experimental investigation indicated that total-pressure recoveries comparable with those attainable with well designed nose inlets were obtained with the side inlets when all the boundary layer ahead of the inlets was removed. Serious drag penalties resulted at a Mach number of 2.0 from the use of blunt-cowl leading edges. However, sharp-lip inlets produced large losses in thrust for the take-off condition. These thrust penalties which are associated with the low-speed operation of the sharp-lip inlet designs can probably be avoided without impairing the supersonic performance of the inlet by the use of auxiliary inlets or blow-in doors.

NACA RM E51K29

LOITERING AND RANGE PERFORMANCE OF TURBOJET-POWERED AIRCRAFT DETERMINED BY OFF-DESIGN ENGINE CYCLE ANALYSIS. Stanley L. Koutz and Reece V. Hensley. February 1952. 45p. diagrs., tab. (NACA RM E51K29)

The loitering and range performance of airplanes equipped with several different turbojet engines was analytically investigated by applying the results of off-design cycle analyses to specific airplane characteristics. The method of off-design cycle analysis is presented herein and is verified by a check with experimental data. For all engines considered, the loitering and the range fuel flows obtained with rated tail-pipe nozzle area, variable engine speed operation were within 2 or 3 percent of the optimum fuel flow obtainable with any method of engine operation. The optimum loitering altitude generally occurred between approximately 25,000 and 35,000 feet with corresponding optimum flight Mach numbers of 0.4 to 0.65. In general, the optimum range fuel flows occurred at 3000 to 5000 feet higher altitude and at approximately 0.15 higher flight Mach numbers than the optimum loitering fuel flow.

NACA RM E52K04

INTERNAL PERFORMANCE OF SEVERAL TYPES OF JET-EXIT CONFIGURATIONS FOR SUPERSONIC TURBOJET AIRCRAFT. William A. Fleming. January 1953. 28p. diagrs. (NACA RM E52K04)

Internal performance characteristics of a convergent nozzle, fixed convergent-divergent nozzles, an adjustable plug-type convergent-divergent nozzle, and jet ejectors were investigated over a wide range of pressure ratios. These data are summarized to provide an overall picture of jet-exit performance and thereby serve as an aid in selecting the most suitable jet-exit configurations for supersonic aircraft.

NACA RM E52K14

FORCE AND PRESSURE RECOVERY CHARACTERISTICS AT SUPERSONIC SPEEDS OF A CONICAL SPIKE INLET WITH BYPASSES DISCHARGING IN AN AXIAL DIRECTION. J. L. Allen and Andrew Beke. January 1953. 27p. diagrs., photos., tab. (NACA RM E52K14)

Force and pressure-recovery characteristics of a nacelle-type conical-spike inlet with two fixed-area bypasses are presented for flight Mach numbers of 1.6, 1.8, and 2.0 and for angles of attack from 0° to 9°. The inlet was designed to attain a mass-flow ratio of unity at a flight Mach number of 2.0. The horizontally opposed bypasses were 6 inlet diameters aft of the inlet entrance. At a flight Mach number of 2.0, the discharge of 23 percent of the critical mass flow of the inlet by means of bypasses (thus retaining critical inlet flow) increased the drag only one-fifth of the additive drag that would result if the same amount of air were spilled behind on inlet normal shock. The total-pressure recovery of the diffuser was not significantly reduced. Similar results were obtained at other flight Mach numbers.

NACA RM E52K17

PERFORMANCE OF DOUBLE-SHROUD EJECTOR CONFIGURATION WITH PRIMARY PRESSURE RATIOS FROM 1.0 TO 10. Donald P. Hollister and William K. Greathouse. February 1953. 34p. diagrs., tabs. (NACA RM E52K17)

A brief investigation was made to determine the performance characteristics of a double-shroud cooling-air ejector configuration. Two convergent primary nozzles were used to simulate a specific manufacturer's iris-type variable-area nozzle in the open and closed positions. The investigation comprised four phases: (1) obtained performance with no secondary or tertiary air flow (cooling-air passages blocked), (2) determining the tendency for backflow to occur in either cooling-air passage, (3) determining the sensitivity of flow in one passage to that in the other, and (4) obtaining pumping and thrust characteristics with secondary and tertiary

DECLASSIFIED NACA RESEARCH REPORTS

air flow. The experimental results showed that the performance with the cooling-air passages blocked was typical of that for single ejectors having diameter and spacing ratios similar to those used in this investigation. There was a tendency for backflow to occur, but the magnitude of such flow was relatively small. The weight flow of each ejector was shown to be essentially independent of the other, and the closed primary-nozzle configuration was found to be generally capable of pumping more cooling air than the open primary-nozzle configuration. Gains in gross thrust were observed for both configurations, with losses occurring only at low secondary and tertiary pressure ratios.

NACA RM E52K18

INVESTIGATION AT SUPERSONIC SPEEDS OF AN INLET EMPLOYING CONICAL FLOW SEPARATION FROM A PROBE AHEAD OF A BLUNT BODY. Donald P. Hearth and Gerald C. Gorton. January 1953. 32p. diagrs., photos., tab. (NACA RM E52K18)

An experimental investigation was conducted on an inlet employing conical flow separation from a probe extending upstream from a hemispherical-nosed centerbody. Data were obtained at free-stream Mach numbers from 1.6 to 2.0 and angles of attack from 0° to 9°. Pressure-recovery and drag characteristics for the inlet were very nearly comparable with those for a conical-spike inlet at zero angle of attack and design Mach number of 2.0, but compared less favorably at Mach numbers below 2.0. A large reduction in pressure recovery and mass flow was obtained at angle of attack. However, an investigation on the use of probes offset from the inlet center line indicated that the angle-of-attack performance could be appreciably improved if the probe were alined with the stream direction.

NACA RM E52K26

ANALYSIS OF SEVERAL METHODS OF PUMPING COOLING AIR FOR TURBOJET-ENGINE AFTERBURNERS. John C. Samuels and Herbert Yanowitz. February 1953. 54p. diagrs. (NACA RM E52K26)

Several methods of pumping air to an annular cooling passage surrounding a typical axial-flow turbojet-engine afterburner were evaluated and compared on the basis of thrust and specific fuel consumption of the systems. Each system was analyzed over a range of afterburner-wall temperatures, flight Mach numbers, and exhaust-gas temperatures at sea level and 35,000 feet. Ram pressure recovery, boundary-layer pressure recovery, and the engine-jet actuated ejector appear to be satisfactory systems at high Mach numbers. Cooling with compressor-exit air bleed was found to be unsatisfactory, but the use of compressor-exit bleed air as the primary fluid in a high-performance ejector was satisfactory. The use of an auxiliary compressor driven from the engine shaft increased the thrust and decreased the specific fuel consumption of the engine for many of the conditions investigated.

NACA RM E53K03

ANALYSIS OF PERFORMANCE OF FOUR SYMMETRICAL-DIAGRAM-TYPE SUBSONIC INLET-STAGE AXIAL-FLOW COMPRESSORS. Robert J. Jackson. January 1954. 72p. diagrs., photos. (NACA RM E53K03)

The main results of an experimental investigation of four axial-flow single-stage compressors having a hub-tip radius ratio of 0.5 and designed for symmetrical velocity diagrams at all radii were as follows: Because of the action of radial equilibrium, the high-pressure-ratio and low-weight-flow type of design incurred high tip-region blade loadings and, consequently, high losses. Therefore, the most suitable use for the symmetrical-velocity-diagram type of design is for higher specific weight flow and (for a given Mach number limit) lower pressure ratio designs. A diffusion factor correlation was obtained, for a given solidity, among compressor and cascade-predicted deviation angles, and among compressor losses for the range of diffusion factor exceeding approximately 0.5. The available data indicated that the assumption of simplified radial equilibrium was a valid one. In order to predict the radial variation of air velocities, it was necessary to consider the radial variation of entropy, which was especially significant after the stators.

NACA RM E54I27a

PRELIMINARY INVESTIGATION OF THE STRENGTH AND ENDURANCE OF PLASTIC-IMPREGNATED FIBERGLASS COMPRESSOR BLADES. Donald F. Johnson and André J. Meyer, Jr. January 1955. 21p. diagrs., photos. (NACA RM E54I27a)

A complete set of third-stage compressor rotor blades fabricated from laminated fiberglass cloth and bonded with a phenolic resin were operated in a conventional engine for 105 hours. All blades were in perfect condition upon disassembly. Also, a number of laboratory tests were conducted on additional blades to determine moduli of elasticity and rigidity, strength in both tension and bending, internal damping, and the fatigue limit of the blade material.

NACA RM E54K02

PRELIMINARY INVESTIGATION OF A TECHNIQUE OF PRODUCING A HEATED CORE IN A SUPERSONIC WIND-TUNNEL STREAM. Morris D. Rousso and Milton A. Beheim. February 1955. 22p. photos., diagrs. (NACA RM E54K02)

An investigation conducted at Mach numbers 1.9 and 3.0 has shown that a central core of air of high stagnation temperature can be produced in the test section of a supersonic wind tunnel. Air heated by combustion was injected into the tunnel in a streamwise direction near the tunnel throat. The effects of core-nozzle location and dimensions, core to main air stream total-pressure ratio, and core stagnation temperature on the size and shape of temperature contours and on Mach number profiles in the test section were determined.

NACA RM L8K04a

FLIGHT TESTS AT TRANSONIC AND SUPERSONIC SPEEDS OF AN AIRPLANE-LIKE CONFIGURATION WITH THIN STRAIGHT SHARP-EDGE WINGS AND TAIL SURFACES. Clarence L. Gillis and Jesse L. Mitchell. January 5, 1949. 37p. diagrs., photos., tab. (NACA RM L8K04a)

Rocket-powered models of a configuration having thin, straight, sharp-edge wings and tail surfaces were flight-tested at transonic and low supersonic speeds. Rather large longitudinal trim changes occurred. Decreased longitudinal control effectiveness was evident at supersonic speeds. The static directional stability appears adequate but a snaking oscillation generally existed at supercritical Mach numbers.

NACA RM L8K05

DRAG MEASUREMENTS IN FLIGHT ON THE 10-PERCENT-THICK AND 8-PERCENT-THICK WING X-1 AIRPLANES. John J. Gardner. November 19, 1948. 17p. diagrs., photo. (NACA RM L8K05)

Contains results of drag measurements of X-1 airplanes with 8-percent-thick wing, 6-percent-thick tail and 10-percent-thick wing, 8-percent-thick tail in Mach number range from 0.7 to 1.3. Brief comparison made between airplane and wing section lift-drag ratios.

NACA RM L9D08

ESTIMATED TRANSONIC FLYING QUALITIES OF A TAILLESS AIRPLANE BASED ON A MODEL INVESTIGATION. Charles J. Donlan and Richard E. Kuhn. June 8, 1949. 63p. diagrs., photos., tabs. (NACA RM L9D08)

An analysis of the estimated flying qualities of a tailless airplane with the wing quarter-chord line swept back 35°, an aspect ratio of 3, and taper ratio of 0.6 in the Mach number range from 0.40 to 0.91 has been made. The longitudinal stability and control were investigated and estimates made of the period and damping of the short-period longitudinal and lateral oscillations. Also included are the wind-tunnel test data on which the analysis is based. Data include longitudinal and lateral stability and control-force data, effect of speed brakes, canopies, fins, and wing-alone tests. Tuft studies of flow on wings, fins, and behind speed brakes are included throughout the Mach number range.

NACA RM L9J07a

INVESTIGATION OF THE DYNAMIC LATERAL STABILITY AND CONTROL CHARACTERISTICS OF A MODEL OF A FIGHTER AIRPLANE WITHOUT A HORIZONTAL TAIL AND EQUIPPED WITH EITHER SINGLE OR TWIN VERTICAL TAILS. John W. Draper and Robert W. Rose. November 15, 1949. 20p. diagrs., photos., tab. (NACA RM L9J07a)

An investigation has been conducted in the Langley free-flight tunnel to compare the lateral stability and control characteristics of a model of a fighter airplane without a horizontal tail and equipped either with a single vertical tail mounted on the fuselage or with twin vertical tails of the same tail volume mounted on the wing. The investigation included force and flight tests of the model with both tail configurations.

NACA RM L50K03

INVESTIGATION OF THE AERODYNAMIC EFFECTS OF AN EXTERNAL STORE IN COMBINATION WITH 60° DELTA AND LOW-ASPECT-RATIO TAPERED WINGS AT A MACH NUMBER OF 1.9. Ellery B. May, Jr. January 9, 1951. 46p. diagrs., photos. (NACA RM L50K03)

A wind-tunnel investigation was made of an external store of fineness ratio 8.6 which was located on the chord plane of several wings in the Langley 9- by 12-inch supersonic blowdown tunnel. The work was carried out at a Mach number of 1.9 on wings having 60° leading-edge sweepback and unswept trailing edges with taper ratios of 0 and 0.28, and on an unswept wing having a taper ratio of 0.625. Investigation was made to determine the aerodynamic effects of store position, the loading breakdown between the store and the inner and outer wing panel of one wing, and the effects of the store on control characteristics. The test Reynolds numbers ranged between 2.3×10^6 and 4.0×10^6.

NACA RM L50K16

WING-ON AND WING-OFF LONGITUDINAL CHARACTERISTICS OF AN AIRPLANE CONFIGURATION HAVING A THIN UNSWEPT TAPERED WING OF ASPECT RATIO 3, AS OBTAINED FROM ROCKET-PROPELLED MODELS AT MACH NUMBERS FROM 0.8 TO 1.4. Clarence L. Gillis and A. James Vitale. March 14, 1951. 52p. diagrs., photos., tabs. (NACA RM L50K16)

Flight tests were conducted on three rocket-propelled models of an airplane configuration, two models having thin unswept tapered wings of aspect ratio 3 and hexagonal airfoil sections, and the third having no wing. The two winged models had wings of different stiffness characteristics. Aerodynamic derivatives defining the static and dynamic longitudinal stability, control, trim, and drag characteristics of the configuration were obtained over a Mach number range from 0.8 to 1.4. For some of the aerodynamic derivatives the separate effects of the wing, tail, and fuselage were determined. Some buffeting and maximum lift information was obtained at high subsonic speeds.

NACA RM L51K05

TOTAL-PRESSURE RECOVERY OF A CIRCULAR UNDERSLUNG INLET WITH THREE DIFFERENT NOSE SHAPES AT A MACH NUMBER OF 1.42. Charles F. Merlet and Howard S. Carter. February 1952. 37p. diagrs., photos. (NACA RM L51K05)

Total-pressure recoveries at the inlet and after diffusion and shadowgraphs are presented for a circular underslung inlet located well forward on a body of revolution. Three nose shapes, varying in bluntness, were tested at three angles of attack and one angle of yaw in a free-air jet at a Mach number of 1.42, and over a range of mass-flow ratios from 0.3 to 0.9.

NACA RM L51K06

LONGITUDINAL STABILITY AND DRAG CHARACTERISTICS AT MACH NUMBERS FROM 0.75 TO 1.5 OF AN AIRPLANE CONFIGURATION HAVING A 60° SWEPT WING OF ASPECT RATIO 2.24 AS OBTAINED FROM ROCKET-PROPELLED MODELS. A. James Vitale, John C. McFall, Jr., and John D. Morrow. April 1952. 43p. diagrs., photos., tabs. (NACA RM L51K06)

Flight tests were conducted on a rocket-propelled airplane configuration model and on a drag model, each having a 60° swept wing of aspect ratio 2.24 with different fuselages. The longitudinal stability, control, and drag characteristics of the airplane configuration were determined over a Mach number range of 0.75 to 1.50. Wing-plus-interference minimum drag was obtained from the drag model over a Mach number range of 0.90 to 1.50. For some of the aerodynamic derivatives the separate effects of the wing, tail, and fuselage were obtained.

NACA RM L51K20

SUMMARY OF SOME EFFECTIVE AERODYNAMIC TWISTING-MOMENT COEFFICIENTS OF VARIOUS WING-CONTROL CONFIGURATIONS AT MACH NUMBERS FROM 0.6 TO 1.7 AS DETERMINED FROM ROCKET-POWERED MODELS. H. Kurt Strass. January 1952. 22p. diagrs., photo., 2 tabs. (NACA RM L51K20)

This paper presents a summary of some effective aerodynamic twisting-moment coefficients of various wing-control configurations at Mach numbers from 0.6 to 1.7 as determined by the use of rocket propelled test vehicles which indicated that, within the framework of the necessary assumptions, the value of the effective twisting-moment coefficient decreased as the sweepback of the aileron hinge axis is increased. Large changes in the value of the effective twisting-moment coefficient were obtained in the Mach number region from $M \approx 0.8$ to $M \approx 1.2$ with changes in aileron span and location upon the same wing plan form. Above $M \approx 1.2$, the values tended to agree more closely. This factor limits the use of these data to wing-control configurations similar to those tested. Comparative tests of an outboard 0.3-span, 0.25-chord aileron, and a midspan spoiler of approximately the same span length indicate that the twisting moment of the spoiler is about one-third that of the aileron for equal values of rolling effectiveness.

NACA RM L52K17

INVESTIGATION AT TRANSONIC SPEEDS OF A FORWARD-LOCATED UNDERSLUNG AIR INLET ON A BODY OF REVOLUTION. P. Kenneth Pierpont and John A. Braden. January 1953. 109p. diagrs., photos., tabs. (NACA RM L52K17)

Results are given for an experimental investigation of a forward-located underslung scoop mounted on a basic body at Mach numbers from 0.6 to 1.1 and for angles of attack from 0° to 10°. The inlet area was 17.3 percent of the body frontal area. For mass-flow ratios from 0.3 to within 5 percent of the maximum, total pressure recovery in the diffuser in excess of 97 percent was realized at all Mach numbers and angles of attack. External drag of the scoop model at high mass-flow condition was approximately equal to that of the basic body.

NACA RM L52K20a

EFFECTS OF SIZE OF EXTERNAL STORES ON THE AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT AND A 45° SWEPTBACK WING OF ASPECT RATIO 4 AND A 60° DELTA WING AT MACH NUMBERS OF 1.41, 1.62, AND 1.96. Carl R. Jacobsen. January 1953. 55p. diagrs., photos., tab. (NACA RM L52K20a)

An investigation has been made in the Langley 9- by 12-inch supersonic blowdown tunnel to determine the effects of external stores of various sizes on the lift, drag, and pitching-moment characteristics of three wings; an unswept and a 45° sweptback wing having aspect ratios of 4 and taper ratios of 0.6, and a 60° delta wing at Mach numbers of 1.41, 1.62, and 1.96.

* AVAILABLE ON LOAN ONLY.

DECLASSIFIED NACA RESEARCH REPORTS

The size of a Douglas Aircraft Company, Inc., store having a fineness ratio of 8.58 was systematically varied at the 80-percent-semispan station of the unswept and sweptback wing and at the 60-percent-semispan station of the delta wing. Several stores were also tested at various other store locations on the outer 60 percent of each of the wing semispans. For wing areas of 500, 600, and 750 square feet for an unswept, a sweptback, and a delta wing, respectively, the store sizes covered in the investigation provide data for stores ranging in size from a 200-pound bomb to a large jet engine nacelle.

NACA RM L52K21

EFFECT OF LEADING-EDGE CHORD-EXTENSIONS ON SUBSONIC AND TRANSONIC AERODYNAMIC CHARACTERISTICS OF THREE MODELS HAVING 45° SWEPTBACK WINGS OF ASPECT RATIO 4. Kenneth W. Goodson and Albert G. Few, Jr. January 1953. 31p. diagrs., photos., tab. (NACA RM L52K21)

This paper presents the effects of wing leading-edge chord-extensions on the subsonic and transonic high-lift pitching moment and the performance characteristics of three models having wings of 45° sweepback, aspect ratio 4, taper ratio 0.30, and NACA 65A006 airfoil sections parallel to the free stream. The test Reynolds numbers varied from about 0.6×10^6 to 3.25×10^6, depending upon the wing and Mach number. Some tests were made with a full-chord fence installed.

NACA RM L52K28

HINGE-MOMENT CHARACTERISTICS FOR SEVERAL TIP CONTROLS ON A 60° SWEPTBACK DELTA WING AT MACH NUMBER 1.61. K. R. Czarnecki and Douglas R. Lord. January 1953. 31p. diagrs., photos. (NACA RM L52K28)

An investigation has been made at a Mach number of 1.61 and a Reynolds number of 4.2×10^6 to determine the hinge-moment characteristics of a group of tip controls on a 60° sweptback delta wing. The control configurations varied in plan form and in amount of aerodynamic balance. Tests were made over an angle-of-attack range of 0° to 15° and a flap deflection range of -30° to 30°. A comparison of the experimental results with theory is included.

NACA RM L53K03

EFFECT OF LARGE DEFLECTIONS OF A CANARD CONTROL AND DEFLECTIONS OF A WING-TIP CONTROL ON THE STATIC-STABILITY AND INDUCED-ROLL CHARACTERISTICS OF A CRUCIFORM CANARD MISSILE AT A MACH NUMBER OF 2.01. M. Leroy Spearman. December 1953. 20p. diagrs., tabs. (NACA RM L53K03)

An investigation has been conducted in the Langley 4- by 4-foot supersonic pressure tunnel at a Mach number of 2.01 to determine the effect of large deflections of a canard and deflections of a wing-tip control on the static stability and induced-roll characteristics of a cruciform-wing canard-type missile. The missile had a body fineness ratio of 15.7. The tests covered an angle-of-attack range from 0° up to about 27°, a canard deflection range up to 30°, and a wing-tip control deflection up to 20°

NACA RM L53K11

EFFECTS OF A SERIES OF INBOARD PLAN-FORM MODIFICATIONS ON THE LONGITUDINAL CHARACTERISTICS OF TWO UNSWEPT WINGS OF ASPECT RATIO 3.5, TAPER RATIO 0.2, AND DIFFERENT THICKNESS DISTRIBUTIONS AT MACH NUMBERS OF 1.61 AND 2.01. John R. Sevier, Jr. February 1954. 43p. diagrs., photos. (NACA RM L53K11)

Tests of a series of inboard plan-form modifications of two unswept wings of aspect ratio 3.5 and taper ratio 0.2 were made at the Langley 4- by 4-foot supersonic pressure tunnel at Mach numbers of 1.61 and 2.01. Results indicated that, by properly modifying the wing thickness and plan form, significant increases in wing volume can be attained with little or no penalties in drag and actual increases in maximum lift-drag ratio.

NACA RM L53K27

WIND-TUNNEL INVESTIGATIONS AT LOW AND TRANSONIC SPEEDS OF THE FEASIBILITY OF SELF-ACTUATING SPOILERS AS A LATERAL-CONTROL DEVICE FOR A MISSILE. Harleth G. Wiley and William C. Hayes, Jr. January 1954. 24p. diagrs., tab. (NACA RM L53K27)

Results are presented of wind-tunnel investigations of the lateral-control effectiveness of self-actuating spoilers on a thin 60° delta wing up to an angle of attack of about 20° at low speeds and of the aerodynamic moments acting on an isolated self-actuating spoiler through an angle-of-rotation range of 180° at transonic speeds. Presented also are the results of brief tests of spoiler actuating times at low speeds.

NACA RM L54K02

A LIMITED FLIGHT INVESTIGATION OF THE EFFECT OF DYNAMIC VIBRATION ABSORBERS ON THE RESPONSE OF AN AIRPLANE STRUCTURE DURING BUFFETING. Jim Rogers Thompson and John E. Yeates, Jr. January 1955. 29p. diagrs., photos. (NACA RM L54K02)

Limited flight measurements have been made in the high-speed low-lift buffet region of the effect on the buffeting response of dynamic vibration absorbers mounted on the wing tips. The absorbers had 70-pound-moving weights and greatly reduced the response in the tuned mode. Approximate calculations indicated that significant reductions could be produced by an installation weighing considerably less than that tested. The device shows promise both as a buffet alleviator and as a research instrument.

NACA RM L54K11a

EXPERIMENTAL AERODYNAMIC FORCES AND MOMENTS AT LOW SPEED OF A MISSILE MODEL DURING SIMULATED LAUNCHING FROM THE MIDSEMISPAN LOCATION OF A 45° SWEPTBACK WING-FUSELAGE COMBINATION. William J. Alford, Jr., H. Norman Silvers, and Thomas J. King, Jr. February 1955. 36p. diagrs., photo., tabs. (NACA RM L54K11a)

An investigation was made at low speed in the Langley 300-mph 7- by 10-foot tunnel to determine the aerodynamic forces and moments of a missile model during simulated launching from the mid-semispan location of a 45° sweptback wing-fuselage combination. Various chordwise and vertical locations were investigated with and without a flat-sided pylon installed. The angle-of-attack range generally extended from -8° to 28°.

NACA RM L54K12

TRANSONIC LONGITUDINAL AERODYNAMIC EFFECTS OF SWEEPING UP THE REAR OF THE FUSELAGE OF A ROCKET-PROPELLED AIRPLANE MODEL HAVING NO HORIZONTAL TAIL. James H. Parks. January 1955. 30p. diagrs., photo. (NACA RM L54K12)

The transonic longitudinal aerodynamic effects of sweeping up the rear of the fuselage have been investigated in free flight by using rocket-propelled models having no horizontal tails. The models had aspect-ratio-4 wings with both the wings and vertical tails swept back 45°. Static and dynamic longitudinal stability parameters, trim conditions, drag at trim lift, and local downflow values are presented.

NACA RM L54K15a

A THEORETICAL INVESTIGATION OF THE EFFECT OF AUXILIARY DAMPING ON THE LONGITUDINAL RESPONSE OF A TRANSONIC BOMBER CONFIGURATION IN FLIGHT THROUGH CONTINUOUS TURBULENCE. T. F. Bridgland, Jr. March 1955. 26p. diagrs., tab. (NACA RM L54K15a)

A theoretical investigation has been made of the effects of auxiliary pitch-rate damping on the longitudinal response of a transonic bomber configuration in low-altitude flight through continuous rough air. The methods of generalized harmonic analysis are utilized in obtaining the statistical character of the airframe responses to a random gust velocity input. The results of this investigation indicate that, for the airframe and speed range considered, reductions in root-mean-square normal acceleration of about 24 percent and reductions in root-mean-square pitch angle of about 74 percent are possible through the use of auxiliary pitch-rate damping.

NACA RM L54K30

FREE-FLIGHT INVESTIGATION, INCLUDING SOME EFFECTS OF WING AEROELASTICITY, OF THE ROLLING EFFECTIVENESS OF AN ALL-MOVABLE HORIZONTAL TAIL WITH DIFFERENTIAL INCIDENCE AT MACH NUMBERS FROM 0.6 TO 1.5. Roland D. English. January 1955. 11p. diagrs., photo. (NACA RM L54K30)

A free-flight investigation has been made to determine the rolling effectiveness at zero angle of attack of an all-movable horizontal tail at a constant angle of differential incidence of 7° per fin mounted behind a notched delta wing over a Mach number range from 0.6 to 1.5. Two models were tested, one with a stiff wing and one with a flexible wing. The rolling effectiveness of both models was of about the same magnitude at subsonic and supersonic speeds. The rolling effectiveness of the flexible-wing model was about 1.6 times that of the stiff-wing model except in the transonic region.

NACA RM L55A24

FLIGHT AND PREFLIGHT TESTS OF A RAM JET BURNING MAGNESIUM SLURRY FUEL AND UTILIZING A SOLID-PROPELLANT GAS GENERATOR FOR FUEL EXPULSION. Walter A. Bartlett, Jr., and William K. Hagginbothom, Jr. April 1955. 35p. diagrs., photos. (NACA RM L55A24)

Data obtained from the first flight test of a ram jet utilizing a magnesium slurry fuel are presented. The ram jet accelerated from a Mach number of 1.75 to a Mach number of 3.48 in 15.5 seconds. During this period a maximum acceleration of 4.6g was obtained. Maximum values of air specific impulse and gross thrust coefficient were calculated to be 151 seconds and 0.658, respectively. The rocket gas generator used as a fuel-pumping system operated successfully.

NACA RM L55K09

WIND-TUNNEL INVESTIGATION AT TRANSONIC SPEEDS OF A JET CONTROL ON A 35° SWEPT WING. TRANSONIC-BUMP METHOD. Raymond D. Vogler and Thomas R. Turner. February 1956. 17p. diagrs. (NACA RM L55K09)

Results are presented of a wind-tunnel investigation at transonic speeds and at angles of attack of -4° to 16° to determine the characteristics of a jet control on a 35° swept-semispan wing. The control consisted of numerous holes normal to the wing surface located on the 65-percent chord line and extending in a spanwise direction from 0.133 to 0.70 of the semispan. Force and moment data were obtained by using ejected air with pressure ratios as high as 9.7 to 1 between the total pressure in the jets and free-stream static pressure.

NACA RM L55K11

EXPERIMENTAL INVESTIGATION AT HIGH SUBSONIC SPEED OF THE ROLLING STABILITY DERIVATIVES OF A COMPLETE MODEL HAVING A CLIPPED-DELTA WING AND A HIGH HORIZONTAL TAIL. William C. Sleeman, Jr., and Albert G. Few, Jr. February 1956. 32p. diagrs., tab. (NACA RM L55K11)

Rolling-stability derivatives are presented for a complete model having an aspect-ratio-3 clipped-delta wing and a high horizontal tail for a Mach number range of 0.60 to 0.92 and for an angle-of-attack range from 0° to a maximum of 13° for the lower Mach numbers. The wing and delta plan-form horizontal tail were swept back 45° at the leading edge and had NACA 65A006 airfoil sections. Breakdown tests were made to determine contributions of the various component parts to the rolling-stability derivatives.

NACA RM L56C06

PREFLIGHT AND FLIGHT-TEST INVESTIGATION OF A 50-PERCENT-MAGNESIUM 50-PERCENT JP-4 SLURRY FUEL IN A TWIN-ENGINE RAM-JET VEHICLE. Otto F. Trout, Jr., and Thomas L. Kennedy. May 1956. 27p. diagrs., photos. (NACA RM L56C06)

Performance data obtained from the preflight and flight tests of a 50-percent-magnesium 50-percent JP-4 slurry fuel are presented. Using this fuel, the ram-jet vehicle accelerated from a Mach number of 2.23 to 2.56 while climbing from an altitude of 3,320 to 37,940 feet. Data are presented for the values of air specific impulse and gross thrust coefficients over the range of altitudes tested.

NACA RM L56I24a

FLIGHT INVESTIGATION OF A RAM JET BURNING MAGNESIUM SLURRY FUEL AND HAVING A CONICAL SHOCK INLET DESIGNED FOR A MACH NUMBER OF 4.1. Walter A. Bartlett, Jr., and Charles F. Merlet. January 1957. 23p. diagrs., photos. (NACA RM L56I24a)

A ram-jet vehicle having a conical shock inlet diffuser designed for a Mach number of 4.1 and utilizing a magnesium slurry fuel was tested in free flight. Data are presented which show that the vehicle accelerated from a Mach number of 1.73 to a maximum Mach number of 3.84 in 13.2 seconds. During this period a maximum acceleration of 6.1g was measured. Maximum values of air specific impulse of 150 seconds and gross thrust coefficient of 0.76 were calculated.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1305

MEASUREMENT OF AERODYNAMIC FORCES FOR VARIOUS MEAN ANGLES OF ATTACK ON AN AIRFOIL OSCILLATING IN PITCH AND ON TWO FINITE-SPAN WINGS OSCILLATING IN BENDING WITH EMPHASIS ON DAMPING IN THE STALL. A. Gerald Rainey. 1957. iii, 33p. diagrs., photos., (NACA Rept. 1305. Supersedes TN 3643)

The oscillating air forces on a two-dimensional wing oscillating in pitch about the midchord have been measured at various angles of attack and at Mach numbers of 0.35 and 0.7. Large regions of unstable damping in pitch were found. Measurements of the aerodynamic damping of a 10-percent-thick and a 3-percent-thick finite-span wing oscillating in, essentially, the first bending mode indicate no regions of unstable damping for this type of motion over the range of variables covered.

NACA RM A57I09

EFFECTS OF STING-SUPPORT INTERFERENCE ON THE DRAG OF AN OGIVE-CYLINDER BODY WITH AND WITHOUT A BOATTAIL AT 0.6 TO 1.4 MACH NUMBER. George Lee and James L. Summers. December 1957. 28p. diagrs., photos. (NACA RM A57I09)

Various sting-support configurations were tested on two bodies of revolution to determine the interference effects on the foredrag and base drag. The tests were made at a Reynolds number of 8×10^6 based on model length and over a Mach number range of 0.6 to 1.4.

NACA TM 1417

ON THE SPECTRUM OF NATURAL OSCILLATIONS OF TWO-DIMENSIONAL LAMINAR FLOWS. (Über das Spektrum bei Eigenschwingungen ebener Laminarströmungen.) D. Grohne. December 1957. 34p. diagrs. (NACA TM 1417. Translation from Zeitschrift für angewandte Mathematik und Mechanik, v. 34, no. 8-9, August-September 1954, p. 344-357)

If the stability of a laminar flow is investigated by the method of small oscillations, a complicated eigenvalue problem is encountered. Heretofore, attention has been directed toward the isolation of those normal modes of oscillation which are either neutrally stable or which grow in time. The present paper deals with the entire spectrum of characteristic values and the form taken by the associated oscillations.

NACA TN 4017

MOMENTUM TRANSFER FOR FLOW OVER A FLAT PLATE WITH BLOWING. H. S. Mickley and R. S. Davis, Massachusetts Institute of Technology. November 1957. 64p. diagrs., tabs. (NACA TN 4017)

The effect on the boundary layer of blowing air through a porous flat plate into a main airstream flowing parallel to the plate was studied experimentally. Measurements were made of velocity profiles and wall friction coefficients. Mainstream velocities ranging from 17 to 60 feet per second were used, the main-stream Euler number was zero, and a length Reynolds number variation of 4×10^4 to 3×10^6 was investigated.

NACA TN 4029

TURBULENCE MEASUREMENTS IN MULTIPLE INTERFERING AIR JETS. James C. Laurence and Jean M. Benninghoff. December 1957. 37p. diagrs., photos. (NACA TN 4029)

Turbulent and mean-flow characteristics of several noise-suppression multiple-jet nozzles have been determined from hot-wire-anemometer measurements for flow conditions of Mach number 0.3 and Reynolds number of 2.06×10^6 per foot. Turbulent mixing, as indicated by reduced intensity and scale of the turbulence, occurs closer to the nozzle in interfering than in noninterfering jets. The turbulence spectra show that the multiple jets redistribute energy. The more rapid mixing of the interfering jets and shifting of the spectral energy of the interfering jets may explain, in part, the suppression of noise by these nozzles.

NACA TN 4081

EFFECT OF OVERHEATING ON CREEP-RUPTURE PROPERTIES OF S-816 ALLOY AT 1,500° F. John P. Rowe and J. W. Freeman, University of Michigan. December 1957. 75p. diagrs., photos., tabs. (NACA TN 4081)

The effects of overheats to temperatures of 1650°, 1800°, 1900°, and 2000° F were evaluated in terms of the changes in creep-rupture characteristics at 1500° F of S-816 alloy under stresses within the range of rupture strengths of the alloy for 100 to 1000 hours. Overheat periods were predominantly

CURRENT NACA RESEARCH REPORTS

of 2-minute duration and were applied cyclically at approximately 5- or 12-hour intervals. The possible damage from overheating was believed to include internal metal structure changes induced by exposure to the higher temperatures and loss of life by creep if stress was present during the overheats.

NACA TN 4082

ABNORMAL GRAIN GROWTH IN NICKEL-BASE HEAT-RESISTANT ALLOYS. R. F. Decker, A. I. Rush, A. G. Dano, and J. W. Freeman, University of Michigan. December 1957. 70p. diagrs., photos., tabs. (NACA TN 4082)

Controlled laboratory experiments were carried out on samples of bar stock of air- and vacuum-melted Waspaloy, Inconel X-550, and Nimonic 80A alloys to find conditions of heating and hot-working which resulted in abnormal grain growth. These experiments were mainly limited to normal conditions of heating for hot-working and for heat treatment. All the results indicate that small reductions of essentially strain-free material were the basic cause of abnormal grain growth.

NACA TN 4083

EFFECT OF OVERHEATING ON CREEP-RUPTURE PROPERTIES OF HS-31 ALLOY AT 1,500° F. John P. Rowe and J. W. Freeman, University of Michigan. December 1957. 78p. diagrs., photos., tabs. (NACA TN 4083)

The effects of overheating to temperatures of 1,650°, 1,800°, 1,900°, and 2,000° F were evaluated in terms of the changes in creep-rupture characteristics at 1,500° F of HS-31 alloy under stresses within the range of rupture strengths of the alloy for about 100 to 700 hours. Overheat periods were predominantly of 2-minute duration and were applied cyclically at approximately 5- or 12-hour intervals. The possible damage from overheating was believed to include internal metal structure changes induced by exposure to the higher temperatures and loss of life by creep if stress was present during the overheats.

NACA TN 4084

ABNORMAL GRAIN GROWTH IN M-252 AND S-816 ALLOYS. R. F. Decker, A. I. Rush, A. G. Dano, and J. W. Freeman, University of Michigan. November 1957. 61p. diagrs., photos., tabs. (NACA TN 4084)

An experimental investigation was carried out on air- and vacuum-melted M-252 and S-816 alloys to find conditions of heating and hot-working which resulted in abnormal grain growth. The experiments were mainly limited to normal conditions of heating for hot-working and heat treatment and normal temperatures of solution treatment were used to allow grain growth after susceptibility to abnormal grain growth was developed by various experimental conditions. Results indicated that small reductions of essentially strain-free metal were the basic cause of such grain growth.

NACA TN 4092

EXPERIMENTAL DROPLET IMPINGEMENT ON FOUR BODIES OF REVOLUTION. James P. Lewis and Robert S. Ruggeri. December 1957. 61p. diagrs., photos. (NACA TN 4092)

The rate and area of cloud droplet impingement on four bodies of revolution were obtained experimentally in the NACA Lewis icing tunnel. Spheres, ellipsoidal forebodies of fineness ratios of 2.5 and 3.0, and a conical forebody of 30° included angle were studied at angles of attack of 0° to 6°, rotational speeds up to 1200 rpm, and an airspeed of 157 knots. The results are presented in the form of dimensionless impingement parameters in order to cover a wide range of flight and atmospheric conditions.

NACA TN 4102

VELOCITY AND FRICTION CHARACTERISTICS OF LAMINAR VISCOUS BOUNDARY-LAYER AND CHANNEL FLOW OVER SURFACES WITH EJECTION OR SUCTION. E. R. G. Eckert, Patrick L. Donoughe and Betty Jo Moore. December 1957. 57p. diagrs., tabs. (NACA TN 4102)

Dimensionless flow parameters common to both channel and boundary-layer flow were developed in order to determine the extent to which the boundary conditions imposed on the flow by the various geometries influence the flow characteristics. By using these parameters to compare the various flows, the flow on surfaces with fluid ejection and on solid surfaces was found to depend mainly on the local boundary-layer thickness, on the pressure gradient in main-flow direction, and on the rates of ejection. This information forms the basis for general correlations, shows the conditions under which channel and boundary-layer data are interchangeable, and should be useful for calculations by integral methods.

NACA TN 4111

INVESTIGATION OF THE COMPRESSIVE STRENGTH AND CREEP OF 7075-T6 ALUMINUM-ALLOY PLATES AT ELEVATED TEMPERATURES. William D. Deveikis. November 1957. 28p. diagrs., photos., tabs. (NACA TN 4111)

Elevated-temperature compressive-strength test results from room temperature to 600° F and creep test results from 350° F to 500° F are presented for V-groove edge-supported plates of 7075-T6 aluminum alloy. The test results are analyzed to verify procedures for estimating maximum strength from material stress-strain curves and creep-failure stresses from isochronous stress-strain curves. The strength and creep results are also compared with similar results for 2024-T3 aluminum-alloy plates.

CURRENT NACA RESEARCH REPORTS

NACA TN 4125

HEAT TRANSFER AND RECOVERY TEMPERATURES ON A SPHERE WITH LAMINAR, TRANSITIONAL, AND TURBULENT BOUNDARY LAYERS AT MACH NUMBERS OF 2.00 AND 4.15. Ivan E. Beckwith and James J. Gallagher. December 1957. 59p. diagrs., photos. (NACA TN 4125)

An investigation was made of the pressure, equilibrium temperatures, and aerodynamic heat transfer on a sphere and on the nose of a hemisphere cylinder. The heat-transfer coefficients and recovery temperatures from the stagnation point to transition showed good agreement with theories for the laminar boundary layer. Transition occurred at an angular distance from the stagnation point of 10° to 30° at Mach number 2.00 and from 30° to 90° at Mach number 4.15. The heat-transfer coefficients and recovery temperatures in the turbulent boundary layer were in reasonable agreement with simple theories for turbulent flow.

NACA TN 4128

A THERMOCOUPLE SUBCARRIER OSCILLATOR FOR TELEMETERING TEMPERATURES FROM PILOTLESS AIRCRAFT. Clifford L. Fricke. December 1957. 50p. diagrs., photos., tabs. (NACA TN 4128)

An oscillator is described which, in conjunction with the NACA telemetering system, gives a satisfactory method for telemetering temperatures. The design uses a diode-bridge modulator in a phase-shift oscillator; the thermocouple voltage is changed to alternating current and used to shift the phase and hence to change the frequency of oscillation. This method results in an oscillator having a small size, low microphonics, high input resistance, and satisfactory stability if a switch is used to commutate calibration voltages along with the pickups.

NACA TN 4131

TRANSITION-FLIGHT INVESTIGATION OF A FOUR-ENGINE-TRANSPORT VERTICAL-TAKE-OFF AIRPLANE MODEL UTILIZING A LARGE FLAP AND EXTENSIBLE VANES FOR REDIRECTING THE PROPELLER SLIPSTREAM. Louis P. Tosti. December 1957. 35p. diagrs., photos., tab., film suppl. available on request. (NACA TN 4131)

An investigation of the stability and control of a four-engine vertical-take-off transport airplane during the transition from hovering to normal forward flight has been conducted with a remotely controlled free-flight model. The model had a 65-percent-chord flap which was deflected 85° in hovering flight, eight extensible vanes arranged above the wing in a cascade relation, and four propellers located along the wing with the thrust axes essentially parallel to the fuselage axis. It was found that the model could be flown through the transition range satisfactorily except for some difficulty with a yawing divergence at low speeds.

NACA TN 4138

CREEP DEFORMATION PATTERNS OF JOINTS UNDER BEARING AND TENSILE LOADS. E. G. Bodine, R. L. Carlson, and G. K. Manning, Battelle Memorial Institute. December 1957. 36p. diagrs., tabs. (NACA TN 4138)

The interaction of bearing and tensile loads on the creep behavior of joints was studied. A specimen was designed for this study which possessed some of the general features of pin and rivet joint connections and an apparatus was constructed to apply both bearing and tensile loads to the joint model. Deformation measurements were made by use of a photogrid printed on the joint model.

NACA TN 4141

THE USEFUL HEAT CAPACITY OF SEVERAL MATERIALS FOR BALLISTIC NOSE-CONE CONSTRUCTION. Jackson R. Stalder. November 1957. 19p. diagrs. (NACA TN 4141)

An analysis has been made of the heat-absorption characteristics of copper, Inconel-X, graphite, and beryllium. It was found that significant weight saving could be achieved in a ballistic missile heat sink by the use of graphite or beryllium in place of copper. Inconel-X was found to be unsatisfactory because of its low thermal conductivity. It is indicated that large errors in computed temperature distributions in materials can arise if the variation of thermal properties with temperature is not taken into account.

NACA TN 4142

EFFECTS OF LEADING-EDGE BLUNTING ON THE LOCAL HEAT TRANSFER AND PRESSURE DISTRIBUTIONS OVER FLAT PLATES IN SUPERSONIC FLOW. Marcus O. Creager. December 1957. 54p. diagrs., tabs. (NACA TN 4142)

Surface pressures and heat-transfer rates were measured on flat plates with various values of blunting for a Mach number of 4 and Reynolds numbers per inch of 2380 and 6600. Surface pressures were correlated for a wide range of variables by a linear combination of terms obtained from shock-wave boundary-layer interaction theory and blast wave theory. A method was developed to correlate local Reynolds numbers from the present data with data from other sources covering a wide range of test conditions.

CURRENT NACA RESEARCH REPORTS

NACA TN 4152

LAMINAR BOUNDARY LAYER WITH HEAT TRANSFER ON A CONE AT ANGLE OF ATTACK IN A SUPERSONIC STREAM. Eli Reshotko. December 1957. (i), 64p. diagrs., tabs. (NACA TN 4152)

The equations of the compressible laminar boundary layer for the windward streamline in the plane of symmetry of a cone at angle of attack are presented and solved. The heat-transfer rate to this streamline increases significantly with angle of attack. For a surface temperature of absolute zero, the increase is somewhat less than for an insulated surface.

NACA TN 4154

APPROXIMATE CALCULATION OF THE COMPRESSIBLE TURBULENT BOUNDARY LAYER WITH HEAT TRANSFER AND ARBITRARY PRESSURE GRADIENT. Eli Reshotko and Maurice Tucker. December 1957. 34p. diagrs. (NACA TN 4154)

An approximate method for the calculation of compressible turbulent boundary layer with heat transfer and arbitrary pressure gradient is presented. The method involves the momentum integral and moment-of-momentum equations as simplified by using Stewartson's transformation. The Ludwieg-Tillmann skin-friction relation is used in these equations in a form suitable for compressible flow with heat transfer through application of the reference enthalpy concept. A tentative extension of Reynolds analogy is suggested for estimating heat-transfer effects for isothermal surfaces.

NACA TN 4166

AN EXPERIMENTAL AND THEORETICAL STUDY OF THE EFFECT OF FUEL ON PITCHING-TRANSLATION FLUTTER. John L. Sewall. December 1957. 42p. diagrs., tabs. (NACA TN 4166)

Analytical flutter studies were made for 2 two-dimensional fuel-loaded wing models, and the results are compared with experimental results for bending-to-torsion frequency ratios near 1. One of the models was made so that water, simulating fuel, could be carried internally in three compartments separated by sealed spanwise partitions. The flutter speeds of this model for all fuel loads were highest for the compartmental-emptying sequence from front to rear. In the other model, fluid was carried externally in a pylon-mounted fuel tank without baffles. Good agreement between theory and experiment was obtained for both models.

NACA TN 4170

A REEXAMINATION OF THE USE OF SIMPLE CONCEPTS FOR PREDICTING THE SHAPE AND LOCATION OF DETACHED SHOCK WAVES. Eugene S. Love. December 1957. 53p. diagrs. (NACA TN 4170)

A reexamination has been made of the use of simple concepts for predicting the shape and location of detached shock waves. The results show that simple concepts and modifications of existing methods can yield good predictions for many nose shapes and for a wide range of Mach numbers.

NACA TN 4173

AN ANALYTICAL INVESTIGATION OF THE GUST-ALLEVIATING PROPERTIES OF A SIMPLE PITCH DAMPER. Norman L. Crabill. December 1957. 47p. diagrs., tab. (NACA TN 4173)

The response to atmospheric gusts of a lightly damped airplane model flying at a Mach number of 0.7 at sea level has been studied analytically for a fixed elevator and for varying amounts of viscous restraint of a mass-overbalanced elevator. The results indicate that, in a sharp-edge gust, the damping of the airframe mode subsequent to the first peak in the normal-acceleration response can be more than trebled, and, in continuous gusts, a 20-percent reduction in root-mean-square normal acceleration at the center of gravity can be attained over a broad range of elevator viscous restraint.

NACA TN 4181

INVESTIGATION OF THE EFFECTS OF PROPELLER DIAMETER ON THE ABILITY OF A FLAPPED WING, WITH AND WITHOUT BOUNDARY-LAYER CONTROL, TO DEFLECT A PROPELLER SLIPSTREAM DOWNWARD FOR VERTICAL TAKE-OFF. Kenneth P. Spreemann. December 1957. 47p. diagrs., photos. (NACA TN 4181)

Without boundary-layer control an increase in the ratio of flap chord to propeller diameter increased the turning angle but decreased the ratio of resultant force to thrust either in or out of the region of ground effects. The increment of turning angle and the increment of the ratio of resultant force to thrust due to boundary-layer control were, in general, independent of the ratio of flap chord to propeller diameter. The ratios of flap chord to propeller diameter investigated appeared to be too low to provide the turning angles normally required for vertical take-off without boundary-layer control.

CURRENT NACA RESEARCH REPORTS

NACA TN 4184

MEASUREMENT OF STATIC PRESSURE ON AIRCRAFT. William Gracey. November 1957. ii, 71p. diagrs. (NACA TN 4184)

Existing data on the measurement of static pressure by means of static-pressure tubes and fuselage vents at subsonic, transonic, and supersonic speeds are presented. Static-pressure errors are given for isolated tubes and vents and for installations ahead of the fuselage nose, wing tip, and vertical tail fin, and on the fuselage. Various methods of calibrating installations in flight are briefly discussed.

NACA TN 4191

ANALYSIS OF HORIZONTAL-TAIL LOADS IN PITCHING MANEUVERS ON A FLEXIBLE SWEPT-WING JET BOMBER. William S. Aiken, Jr. December 1957. 58p. diagrs., photo., tabs. (NACA TN 4191)

Horizontal-tail loads measured by means of strain gages in pitching maneuvers are analyzed to determine wing-fuselage aerodynamic-center position, zero-lift pitching-moment coefficients, airplane pitching moment of inertia, and radius of gyration. The flight-determined values of aerodynamic-center position for rigid conditions and the zero-lift pitching-moment coefficients were in some disagreement with the wind-tunnel data for the Mach number range of the tests (0.42 to 0.81). The pitching moment of inertia determined from the flight data for rigid-wing conditions agreed with calculations based on ground tests.

NACA TN 4192

THREE-DEGREE-OF-FREEDOM EVALUATION OF THE LONGITUDINAL TRANSFER FUNCTIONS OF A SUPERSONIC CANARD MISSILE CONFIGURATION INCLUDING CHANGES IN FORWARD SPEED. Ernest C. Seaberg. December 1957. 29p. diagrs., photo., tabs. (NACA TN 4192. Supersedes RM L54C02)

The longitudinal transfer functions presented are in the form of frequency-response plots for several flight conditions. For a constant Mach number, the frequency response is shown to vary with angle of attack, mainly in the region of low-frequency airframe operation. A comparison of the frequency responses thus obtained with those in which the forward speed change is neglected also shows significant variation in the low-frequency region. The additional derivatives necessary for this study were obtained for a Mach number range from transonic to approximately 1.8.

UNPUBLISHED PAPERS

N-56067*

CERTAIN REGULARITIES IN THE PLASTIC DEFORMATION AND FRACTURE OF METALS IN TENSION. (Nekotorye zakonomernosti plasticheskoi deformatsii i razrusheniya metallov pri rastyazhenii). V. A. Pavlov and K. A. Vshivtseva. May 1957. 14 p. diagrs., photo., tab. Translation from Fizika Metallov i Metallovedenie, v.1, issue 2, 1955. (Ask for N-56067*)

Experimental data are presented regarding the dependence on temperature of the total and uniform elongation and of the change in the character of fracture under tension of cadmium, tin, magnesium, and iron. The temperature range covered was in most cases from -180° C to +150° C, and in the case of magnesium, to about +270° C. Regularities in the behavior of the flow limit, ultimate strength, total and uniform elongation are noted, and certain peculiarities in the behavior of iron are pointed out. The connection between these regularities and the type of fracture at different temperatures is discussed.

UNPUBLISHED PAPERS

N-56796*

SPECTRUM ANALYSIS OF HOMOGENEOUS TURBULENCE. (Spektralanalyse der homogenen Turbulenz.) Walter Tollmien. 12p. diagr. Translation from Zeitschrift fur Flugwissenschaften, v.4, no.5-6, May-June 1956, p.195-198. (Ask for N-56796*)

The basic considerations on the spectrum of homogeneous turbulence are deduced by starting from the spectrum of the velocity fluctuations. This manner of deduction is more instructive than earlier methods and also gives some new results.

NACA RM A51L17a

THE EFFECT OF VARIOUS MISSILE CHARACTERISTICS ON AIRFRAME FREQUENCY RESPONSE. Howard F. Matthews and Walter E. McNeill. January 1952. 16p. diagrs. (NACA RM A51L17a)

The frequency response of two important airframe characteristics were calculated for a cruciform, variable-incidence, air-to-air missile. Plots of amplitude ratio and phase angle as a function of angular frequency are presented to show the effects of the importance, accuracy, and the nonlinearity of certain aerodynamic derivatives, altitude and Mach number variation, and aeroelasticity.

NACA RM A54L08

THE LONGITUDINAL CHARACTERISTICS AT MACH NUMBERS UP TO 0.92 OF SEVERAL WING-FUSELAGE-TAIL COMBINATIONS HAVING SWEPT-BACK WINGS WITH NACA FOUR-DIGIT THICKNESS DISTRIBUTIONS. Fred B. Sutton and Jerald K. Dickson. March 1955. 128p. diagrs., photos., tab. (NACA RM A54L08)

The investigation was conducted in the Ames 12-foot pressure wind tunnel through an angle-of-attack range at a Reynolds number of 8 million at low speed and at Mach numbers from 0.25 to 0.92 at a Reynolds number of 2 million. Wing sweepback was 40°, 45°, and 50°. Several wing fences were tested at each sweep angle and the effects of a horizontal tail were determined at several tail heights.

NACA RM A54L20

EFFECTS OF TAPER RATIO ON THE LONGITUDINAL CHARACTERISTICS AT MACH NUMBERS FROM 0.6 TO 1.4 OF A WING-BODY-TAIL COMBINATION HAVING AN UNSWEPT WING OF ASPECT RATIO 3. James L. Summers, Stuart L. Treon, and Lawrence A. Graham. March 1955. 45p. diagrs., photo. (NACA RM A54L20)

A wind-tunnel investigation from 0.6 to 1.4 Mach number has been made to determine the effects of a variation in wing taper ratio from 0 to 1.0 on the lift, pitching-moment, and drag characteristics of a wing-body combination having a wing with an unswept 0.50-chord line. The wings were of aspect ratio 3 with NACA 64A003 airfoil sections normal to the midchord line. The Reynolds number was 1.5 million. The wing-body combinations were also tested with a tail.

NACA RM A55K21a

FULL-SCALE WIND-TUNNEL TESTS OF THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF THE XV-1 CONVERTIPLANE IN THE AUTOROTATING FLIGHT RANGE. David H. Hickey. May 1956. 64p. diagrs., photos., tabs. (NACA RM A55K21a)

Force and moments were measured for the XV-1 convertiplane at 75 to 150 knots. Rotor on and off and propeller powered and off configurations were investigated. The characteristics of the V-tab horizontal tail and its downwash field were studied. Lift interference between fixed wing and rotor and possible means of drag reduction were considered.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A55L13

THE INFLUENCE OF SURFACE INJECTION ON HEAT TRANSFER AND SKIN FRICTION ASSOCIATED WITH THE HIGH-SPEED TURBULENT BOUNDARY LAYER. Morris W. Rubesin. February 1956. 16p. diagrs. (NACA RM A55L13)

It is shown from existing analyses that distributed surface injection reduces greatly both skin friction and heat transfer of turbulent boundary layers. Data for skin friction and heat transfer at Mach numbers 0, 2.0, and 2.7 are shown to compare rather well with the analyses. Also, an example is included to indicate the effectiveness of transpiration cooling.

NACA RM A55L13c

AERODYNAMICS OF BODIES, WINGS, AND WING-BODY COMBINATIONS AT HIGH ANGLES OF ATTACK AND SUPERSONIC SPEEDS. Jack N. Nielsen, J. Richard Spahr, and Frank Centolanzi. February 1956. 12p. diagrs. (NACA RM A55L13c)

Maximum lift coefficients are presented for triangular and rectangular wings, together with downwash measurements behind a rectangular wing at large angles of attack. It is shown that nonlinear variations of panel normal force, hinge moment, and bending moment for cruciform missiles at high angles of attack can be calculated using a vortex model.

#NACA RM E7K07, by Rowe, Ordin, and Diehl

NACA RM E50D04

INVESTIGATION OF COMBUSTION IN 16-INCH RAM JET UNDER SIMULATED CONDITIONS OF HIGH ALTITUDE AND HIGH MACH NUMBER. T. J. Nussdorfer, D. C. Sederstrom, and E. Perchonok. June 27, 1950. 53p. diagrs., photos., tabs. (NACA RM E50D04)

Results obtained with three different burner configurations in a connected-pipe investigation of a 16-inch ram jet are presented. The radial position of the fuel injector and the engine-outlet area both affected burner performance. For a given configuration, only slight changes in total-pressure ratio across the combustion chamber were obtained over the complete range of operation. With one burner, combustion efficiencies obtained at a combustion-chamber-inlet static pressure of 800 pounds per square foot absolute were greater than those obtained at 1920 pounds per square foot absolute.

NACA RM E50H31

NACA RESEARCH ON COMBUSTORS FOR AIRCRAFT GAS TURBINES. I - EFFECT OF OPERATING VARIABLES ON STEADY-STATE PERFORMANCE. Walter T. Olson and J. Howard Childs. October 18, 1950. 55p. diagrs., tab. (NACA RM E50H31)

Some of the systematic research conducted by the NACA on aircraft gas-turbine combustors is reviewed. Trends depicting the effect of inlet-air pressure, temperature, and velocity and fuel-air ratio on performance characteristics, such as combustion efficiency, maximum temperature rise attainable, pressure loss, and combustor-outlet temperature distribution are described for a variety of turbojet combustors of the liquid-fuel type. These trends are further discussed as effects significant to the turbojet engine, such as altitude operational limits, specific fuel consumption, thrust, acceleration, and turbine life.

NACA RM E50I07

TURBOJET COMBUSTOR EFFICIENCY AT HIGH ALTITUDES. Walter T. Olson, J. Howard Childs, and Edmund R. Jonash. October 27, 1950. 51p. diagrs., photo. (NACA RM E50I07)

Results of investigations of turbojet combustor efficiency at high altitudes are presented to illustrate the effects of (1) combustor operating conditions, (2) combustor design, and (3) fuel characteristics. Decreased combustion efficiencies obtained at low combustor pressures and temperatures were improved by providing for increased volume in the flame zone, gradual admission of air into the combustion space, and increased fuel volatility. Matching of the combustor design, the fuel injection characteristics, and the fuel volatility is required for optimum-combustion-efficiency operation.

NACA RM E50J03

VAPOR-FUEL-DISTRIBUTION EFFECTS ON COMBUSTION PERFORMANCE OF A SINGLE TUBULAR COMBUSTOR. Richard J. McCafferty. December 13, 1950. 27p. diagrs., photo. (NACA RM E50J03)

The effect of hydrocarbon fuel distribution and fuel state on combustion performance of a single tubular combustor at simulated altitude conditions was determined by operating with liquid MIL-F-5616 and gaseous propane fuels and distributing the propane in the primary combustion zone with four fuel-injector designs. Results indicate that performance is influenced by fuel distribution because the altitude operational limits and combustion efficiencies could be varied considerably by use of different fuel injectors that provided different fuel-air mixtures. Vapor fuel gave better performance than the liquid fuel injected by standard pressure-atomizing nozzle.

UNAVAILABLE; contains proprietary or obsolete information.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E51B21

LIQUID-FUEL-DISTRIBUTION AND FUEL-STATE EFFECTS ON COMBUSTION PERFORMANCE OF A SINGLE TUBULAR COMBUSTOR. Richard J. McCafferty. May 1, 1951. 38p. diagrs., tab. (NACA RM E51B21)

The effect of liquid-hydrocarbon-fuel distribution on combustion performance of a single tubular combustor at simulated-altitude conditions was determined by distributing liquid MIL-F-5624 fuel with pressure-atomizing nozzles and solid-stream injectors. The effect of fuel state on performance was obtained by comparison with gaseous-fuel-distribution data from a previous investigation. Results indicate liquid-fuel distribution within the primary combustion zone affects performance but to a lesser degree than gaseous-fuel distribution. Gaseous fuel provided higher altitude operational limits and efficiencies than liquid fuel.

NACA RM E51K30

COMBUSTION EFFICIENCY PERFORMANCE OF A MIL-F-5624 TYPE FUEL AND MONOMETHYL-NAPHTHALENE IN A SINGLE VAPORIZING-TYPE COMBUSTOR. Anthony W. Jones and William P. Cook. February 1952. 26p. diagrs., photos., tabs. (NACA RM E51K30)

The performance (combustion efficiency and blowout) of a conventional turbojet fuel, MIL-F-5624 (JP-3), and a low-volatility, high-density hydrocarbon, monomethylnaphthalene, in a single vaporizing type combustor for variations in inlet conditions is presented in this report. The MIL-F-5624 type fuel burned over a wider range of operating conditions and gave combustion efficiencies 2 to 16 percent higher than monomethylnaphthalene. Heat-input rate had little effect on the combustion efficiency of each fuel in the range investigated.

NACA RM E51L04

EVALUATION OF FIVE CONICAL CENTER-BODY SUPERSONIC DIFFUSERS AT SEVERAL ANGLES OF ATTACK. Gerald W. Englert and Leonard J. Obery. May 1952. 29p. diagrs., photos., tab. (NACA RM E51L04)

Five supersonic inlets having conical center bodies were investigated in a 16-inch ram-jet engine with and without combustion at Mach numbers of 1.7, 1.9, and 2.0 and angles of attack from 0° to 10°. Four of the inlets were of the low-mass-flow-ratio type whereas the fifth inlet was of the high-mass-flow-ratio type. The stable operating range of the four low-mass-flow-ratio inlets decreased considerably as the angle of attack was increased despite an increase of the cone angle or the use of boundary-layer bleed. The stable range of the high-mass-flow-ratio inlet increased considerably both at 0° and at greater angles of attack as the free-stream Mach number was decreased. Free-stream Mach number, angle of attack, and inlet type had negligible effects on combustion efficiency, temperature ratio, or combustion-chamber inlet Mach number in the supercritical region.

NACA RM E51L14

ALTITUDE PERFORMANCE INVESTIGATION OF SINGLE- AND DOUBLE-ANNULAR TURBOJET-ENGINE COMBUSTORS WITH VARIOUS SIZE FUEL NOZZLES. James L. Harp, Jr., and Kenneth R. Vincent. June 1952. 60p. photos., diagrs., tab. (NACA RM E51L14)

An investigation of the performance of an annular-combustor-type turbojet engine was conducted and the performance of an NACA single-annular combustor having controlled air distribution was compared with that of the standard double-annular combustor. The turbine-discharge temperature profiles, combustion efficiency, altitude limits, and engine performance using both combustors were investigated and compared over a range of altitudes and engine speeds at two flight Mach numbers with four sets of fuel nozzles having different flow rates. The most significant advantages of the single-annular combustor were improved turbine-discharge temperature profile and combustion efficiency. However, these gains were not fully realized in increased thrust and specific fuel consumption because of high pressure loss through the single-annular combustor.

NACA RM E51L21

EFFECT OF FUEL DENSITY AND HEATING VALUE ON RAM-JET AIRPLANE RANGE. Hugh M. Henneberry. February 1952. 56p. diagrs., tabs. (NACA RM E51L21)

An analytical investigation of the effects of fuel density and heating value on the cruising range of a ram-jet airplane was made. Results indicate that with present-day knowledge of chemical fuels, neither very high nor very low fuel densities have any advantages for long-range flight. Of the fuels investigated, the borohydrides and metallic boron have the greatest range potential. Aluminum and aluminum hydrocarbon slurries were inferior to pure hydrocarbon fuel and boron-hydrocarbon slurries were superior on a range basis. It was concluded that the practical difficulties associated with the use of liquid hydrogen fuel cannot be justified on a range basis.

NACA RM E51L24

AN INVESTIGATION AT MACH NUMBERS 2.98 AND 2.18 OF AXIALLY SYMMETRIC FREE-JET DIFFUSION WITH A RAM-JET ENGINE. Henry R. Hunczak. February 1952. 30p. photos., diagrs. (NACA RM E51L24)

An investigation was conducted to determine the effectiveness of a free-jet diffuser in reducing the overall pressure ratios required to operate a free jet with a large air-breathing engine as a test vehicle. Efficient operation of the free jet was determined with and without the considerations required for producing suitable engine-inlet flow conditions. A minimum operating pressure ratio of 5.5 was attained with a ratio of nozzle-exit to engine-inlet area of 1.85. Operation of the free jet with unstable engine-inlet flow (buzz) is also included.

NACA RM E52H25

EFFECT OF WATER VAPOR ON COMBUSTION OF MAGNESIUM-HYDROCARBON SLURRY FUELS IN SMALL-SCALE AFTERBURNER. Leonard K. Tower. October 1952. 39p. diagrs., tabs. (NACA RM E52H25)

Both JP-3 fuel and a slurry of 60 percent powdered magnesium in JP-3 fuel were evaluated in a small-scale afterburner in the presence of large quantities of water vapor. Combustion of the slurry was stable to the highest water-air ratio investigated, 0.18; whereas JP-3 fuel would not burn beyond a water-air ratio of 0.08. By means of small-scale-afterburner data, maximum augmented thrust ratio obtainable from a full-scale engine with water injection and afterburning was calculated to be 1.58 with JP-3 fuel and 2.00 with slurry. The use of slurry in place of JP-3 fuel may shorten take-off distance of some aircraft 17 to 24 percent.

NACA RM E52J23

PRELIMINARY EXPERIMENTS WITH PILOT BURNERS FOR RAM-JET COMBUSTORS. John M. Farley, Robert E. Smith, and John H. Povolny. January 1953. 45p. diagrs., photos., tabs. (NACA RM E52J23)

As part of an overall program to develop a high-performance, high-altitude, low-drag ram-jet combustor, a preliminary development program on can-type pilots has been conducted. A 5-inch-diameter circular pilot and an annular-segment pilot were developed which gave stable operation at an inlet pressure of 10 inches of mercury absolute over a satisfactory range of fuel-air ratios for static-pressure ratios across the pilot ranging from about 1.02 to 1.08. The effects of first-row hole size, longitudinal variation in hole area, fuel-system design, and shroud design on the performance of the pilots were determined. It was estimated that in an actual combustor installation the percentage of air flow through the pilot would be equal to about 35 percent of the cross-sectional area blocked by the pilot.

NACA RM E53B19

EFFECT OF FUEL-AIR RATIO CONCENTRATION IN COMBUSTION ZONE ON COMBUSTION PERFORMANCE OF A 16-INCH RAM-JET ENGINE. A. J. Cervenka, D. W. Bahr, and E. E. Dangle. April 1953. 24p. diagrs., tab. (NACA RM E53B19)

The results of fuel-air ratio and temperature surveys made in the flame stabilizing zone of a 16-inch ram-jet combustor indicated that the distribution of combustible mixture immediately downstream of a flame holder should be mechanically controlled if a preferred mixture composition is to be maintained in that zone. A sloping-baffle combustor configuration gave combustion efficiencies of 90 percent or greater over a range of fuel-air ratios from 0.010 to 0.045.

NACA RM E53C24

INVESTIGATION OF 70 PERCENT TRIMETHYL BORATE - 30 PERCENT METHYL ALCOHOL FUEL MIXTURE IN A SINGLE J33 COMBUSTOR AND IN A J33 TURBOJET ENGINE. Louis J. Schafer, Jr., and Robert O. Hickel. January 1957. 26p. diagrs., photos., tab. (NACA RM E53C24)

An experimental investigation was conducted on a single turbojet engine combustor and on a turbojet engine using a fuel mixture consisting of 70 percent trimethyl borate and 30 percent methyl alcohol. In the single combustor, use of the trimethyl borate fuel resulted in excessive boric oxide deposits in the areas surrounding the air entry holes in the liner of the combustor. In the turbojet engine the boric oxide deposits were excessive; they were most severe on the domes and liners of the combustors, on the outlet screens of the rear bearing cooling-air passages, and in the tailcone and tailpipe.

NACA RM E53F15

EFFECT OF FUEL INJECTOR LOCATION AND MIXTURE CONTROL ON PERFORMANCE OF A 16-INCH RAM-JET CAN-TYPE COMBUSTOR. A. J. Cervenka, Eugene Perchonok, and E. E. Dangle. July 1953. 33p. diagrs., tab. (NACA RM E53F15)

A 16-inch connected-pipe investigation was undertaken to evaluate an existing can-type combustor configuration and to develop this configuration to give a wide operable fuel-air ratio range of high combustion efficiency. Only fuel-injector changes were investigated. Without increasing the combustor cold-flow pressure-drop coefficient of 1.5, acceptable performance was achieved by providing the combustor with a fuel-injection system in which a mixture control sleeve was added upstream of the flame holder to provide a locally stoichiometric mixture at lean as well as rich overall fuel-air ratios.

DECLASSIFIED NACA RESEARCH REPORTS

Combustion efficiencies from 92 to 97 percent were obtained with MIL-F-5624A grade JP-4 fuel over a fuel-air ratio range from 0.012 to 0.056 (the rich limit of the facility) at conditions corresponding to flight at a Mach number of 2.9 and an altitude of 67,000 feet. A comparison is made between the connected-pipe burner performance and the performance of one of the injector configurations which had previously been evaluated during a study of a 16-inch ram-jet engine at a Mach number of 2.0 in the Lewis 8- by 6-foot supersonic wind tunnel.

NACA RM E53I01

EXPERIMENTAL INVESTIGATION OF SCREECHING COMBUSTION IN FULL-SCALE AFTERBURNER. Karl H. Usow, Carl L. Meyer, and Frederick W. Schulze. December 1953. 62p. diagrs., photos., tab. (NACA RM E53I01)

In an effort to extend the existing knowledge of screeching combustion in afterburners, a number of systematic configuration modifications were made to an afterburner installed on an engine in the altitude wind tunnel to determine their effect on the screech characteristics. These modifications included changes in the afterburner diffuser, the fuel system, and the flame holder. Screech characteristics of each modification were observed over a range of simulated altitude flight conditions corresponding to afterburner-inlet total pressures from 2200 to 4200 pounds per square foot absolute. The observations made during this investigation indicate that some changes in the geometry of the afterburner diffuser and flame holder have a pronounced effect on the range of conditions over which screeching combustion is encountered; in some cases screech was completely eliminated. In contrast, it was generally found that screeching combustion could not be eliminated by changes in the geometry of the fuel system.

NACA RM E53I03

EFFECT OF INLET-AIR TEMPERATURE ON PERFORMANCE OF A 16-INCH RAM-JET COMBUSTOR. A. J. Cervenka, E. E. Dangle, and Robert Friedman. October 1953. 24p. diagrs., tab. (NACA RM E53I03)

The effect of inlet-air temperature on the combustion efficiency of a 16-inch ram-jet engine was determined in a connected-pipe installation. The engine was operated over a range of fuel-air ratio with several different combustor configurations and two fuel types. Combustion efficiency was found to be as much as 35 percentage points lower at an inlet-air temperature of 160° F than at 600° F. The variation in efficiency was a function of fuel-air ratio and combustor design. With flame-holder designs in which the local fuel-air ratio was maintained near stoichiometric in the burning zone, or at overall ratios near stoichiometric, the temperature effect was slight. When the local fuel-air ratio varied appreciably from stoichiometric, a greater effect was found. These findings are in accordance with previous observations, discussed in a survey of literature, in which the effect of temperature was shown to diminish at the regions of high combustion efficiency. The performance of a sloping-baffle flame holder at an inlet-air temperature of 160° F with gasoline fuel was about the same as with MIL-F-5624A grade JP-4 fuel at 600° F over a range of fuel-air ratio from 0.020 to 0.062.

NACA RM E53L07

PRELIMINARY INVESTIGATION OF AN ANNULAR TURBOJET COMBUSTOR HAVING A CATALYTIC-COATED LINER. Carl T. Norgren and J. Howard Childs. January 1954. 11p. diagrs. (NACA RM E53L07)

The performance of an experimental annular turbojet combustor was investigated at a low-pressure operating condition with an uncoated liner, with an identical liner having a ceramic coating on the inner walls, and with this same liner having a catalytic coating added onto the ceramic coating. The combustion efficiency was approximately the same for all three liners, indicating no gain in performance through the use of the catalytic coating.

NACA RM E53L11b

AERODYNAMIC CHARACTERISTICS OF TWO FLAT-BOTTOMED BODIES AT MACH NUMBER OF 3.12. John R. Jack and Barry Moskowitz. April 1954. 9p. diagrs. (NACA RM E53L11b)

The aerodynamic characteristics of two flat-bottomed bodies having a semicircular and a semielliptical cross section have been determined at a Mach number of 3.12 for a range of angles of attack from -10° to 10° and for Reynolds numbers of 8×10^6 and 14×10^6 (based on model length). A comparison of the flat-bottomed body characteristics with those previously determined for an equivalent cone-cylinder body of revolution shows that significant increases in lift and lift-drag ratio are obtained with a flat bottom. Additional improvement in lift and lift-drag ratio was achieved at positive angles of attack by expanding the plan form in the spanwise direction.

NACA RM E53L15

INVESTIGATION OF CONICAL SUBSONIC DIFFUSERS FOR RAM-JET ENGINES. John M. Farley and Henry J. Welna. March 1954. 40p. diagrs., photos., tabs. (NACA RM E53L15)

The efficiency of a 30° conical diffuser was improved as much as 20 percent and separation was eliminated by the use of vortex generators. The use of splitter cones gave only small efficiency gains, but relatively uniform diffuser-outlet velocity profiles were obtained with the better designs. A configuration which

DECLASSIFIED NACA RESEARCH REPORTS

incorporated both vortex generators and a splitter cone gave efficiencies higher than those obtained with any other splitter-cone configuration and also higher than those obtained when the same vortex generators were used without the splitter cone. Moderate diffuser-efficiency increases were obtained with guide vanes; however, in all cases combustion occurred in the vane wakes.

NACA RM E53L18a

ALTITUDE PERFORMANCE AND OPERATIONAL CHARACTERISTICS OF AN XT38-A-2 TURBOPROP ENGINE. R. H. Essig and F. W. Schulze. March 1954. 43p. diagrs., photos., tab. (NACA RM E53L18a)

The overall engine performance and the starting and windmilling characteristics of an XT38-A-2 turboprop engine have been investigated in the NACA Lewis altitude wind tunnel. The simulated flight conditions ranged from altitudes of 5,000 to 45,000 feet at a flight Mach number of 0.30 and from Mach numbers of 0.301 to 0.557 at an altitude of 35,000 feet. The engine, equipped with a standard-area exhaust nozzle, was operated with independent control of fuel flow and propeller pitch; operation was thereby allowed over a wide range of engine conditions. Windmilling characteristics were obtained at altitudes of 15,000 and 35,000 feet. Analysis of the performance maps obtained at each flight condition revealed that both altitude and flight Mach number had a major effect on corrected engine variables. The large reductions in corrected shaft horsepower occurring when the altitude was increased were the result of decreases in compressor and turbine efficiencies. Windmilling engine starts were made at altitudes as high as 35,000 feet at an engine speed of 2,000 rpm.

NACA RM E53L22

REVIEW OF HIGH-PERFORMANCE AXIAL-FLOW-COMPRESSOR BLADE-ELEMENT THEORY. Seymour Lieblein. April 1954. 34p. diagrs. (NACA RM E53L22)

This report presents a review of current compressor blade-element theory with particular emphasis on application to the transonic high-performance compressor. A discussion of the significant parameters of total-pressure loss and deviation angle is presented, and an indication of the extent of available knowledge and the problems involved in the determination of blade-element characteristics is given. Some recent results and considerations in this pursuit and suggestions for further avenues of investigation are indicated.

NACA RM E53L29a

DESIGN AND EXPERIMENTAL INVESTIGATION OF TRANSONIC TURBINE WITH SLIGHT NEGATIVE REACTION ACROSS ROTOR HUB. Warner L. Stewart, Robert Y. Wong, and David G. Evans. March 1954. 40p. diagrs., photo., tabs. (NACA RM E53L29a)

The design and experimental investigation of a transonic turbine are presented herein. This turbine was designed for a slight overall negative reaction across the hub. Because of the increased flow Mach number level, the design procedure used was on a quasi-three-dimensional basis. The results of the experimental investigation indicated that the design point was obtained at a total efficiency of 0.85 with one point in efficiency lost in exit whirl. Design equivalent specific-work output occurred 3 percent below the turbine limiting-loading point. This checked closely with the value of 5 percent obtained theoretically with design conditions. From the experimental results it was concluded that, under the prescribed design conditions, transonic turbines can be operated with efficiencies of at least 0.85. The quasi-three-dimensional design procedure was found to be sufficiently rigorous that the design conditions, although critical from a limiting-loading standpoint, could be met.

NACA RM E54B02

A SUMMARY OF PRELIMINARY INVESTIGATIONS INTO THE CHARACTERISTICS OF COMBUSTION SCREECH IN DUCTED BURNERS. Lewis Laboratory Staff. April 1954. 60p. diagrs., photos. (NACA RM E54B02)

Operation of afterburners and ram-jet combustors at progressively higher fuel-air ratios has increased the occurrence and intensity of screech. Because of the destructive characteristics of screech, considerable effort has been expended in an attempt to understand and control this phenomenon. The present report summarizes NACA work on screech prior to November 1953. To determine the effects of design and operational variables on screech frequency and intensity, studies have been conducted in combustors ranging from 6 to 37 inches in diameter. Attempts to eliminate screech by reducing the driving potential of the gas stream were generally unsuccessful, but the use of an acoustic damper completely eliminated screech in all burner configurations in which it was used.

NACA RM E54F25a

LOW-PRESSURE PERFORMANCE OF EXPERIMENTAL PREVAPORIZING TUBULAR COMBUSTOR USING APPROXIMATELY STOICHIOMETRIC ADMISSION OF FUEL-AIR MIXTURE INTO THE PRIMARY ZONE. Robert R. Hibbard, Allen J. Metzler, and Wilfred E. Scull. August 1954. 38p. diagrs., tabs. (NACA RM E54F25a)

To evaluate the precept of prevaporized, stoichiometric mixture addition to the primary zone of a combustor, an experimental tubular combustor was developed which utilized the outer surface of the flame tube as a fuel vaporizer. The experimental combustor gave higher efficiencies than those obtained with a production model at all conditions and indicated a low tendency to form carbon. However, operation of the experimental combustor was limited by flashback into the vaporizing area at low air velocities or high pressures.

NACA RM E54L15

A METHOD FOR THE ANALYSIS OF COMPOUNDS CONTAINING BORON, CARBON, AND HYDROGEN. Harrison Allen, Jr., and Stanley Tannenbaum. March 1955. 9p. diagrs., tabs. (NACA RM E54L15)

A method is presented for the analysis of boron, carbon, and hydrogen from the combustion of a single sample of an organoboron compound. The method is based on the quantitative combustion of the sample in a steel bomb at high temperature and pressure, with subsequent analysis of the combustion products. It was applied successfully to the analysis of several trialkyl borates and trialkyl boranes; applicability of the method to hydrocarbon analysis was also investigated.

COMPRESSOR-BLADE VIBRATION AND PERFORMANCE IN A J47-23 TURBOJET ENGINE UNDER CONDITIONS OF ROTATING STALL. Morgan P. Hanson, Donald F. Johnson, and André J. Meyer, Jr. June 1955. 18p. diagrs., tab. (NACA RM E54L20a)

An investigation was made of a J47-23 turbojet engine to determine the effects of rotating stall on compressor blade vibration and compressor performance. One to nine stall zones were measured, with the seven stall in predominance. Under normal operation, the maximum vibratory stress measured was ±26,200 psi in the second-stage blades. However, under simulated rapid acceleration conditions, a stress of ±60,000 psi was measured in the second stage. Compressor performance is presented of the operating conditions investigated.

NACA RM E54L23

ANALYSIS OF A PRESSURE-JET POWER PLANT FOR A HELICOPTER. Richard P. Krebs and William S. Miller, Jr. March 1955. 56p. diagrs. (NACA RM E54L23)

A study of the performance of a pressure-jet power plant for a helicopter was made to determine suitable values for the principal design parameters of the system. Compressor pressure ratio, tip-jet temperature, duct area, burner area, and rotor tip speed were varied through appropriate ranges and power-available charts are presented for several combinations of these power-plant parameters. Comparison of a series of pressure-jet power plants installed in a helicopter of 30,000 pounds gross weight is made on the basis of hovering duration and flight range.

NACA RM E54L29

PERFORMANCE OF A SUPERSONIC COMPRESSOR WITH SWEPT AND TILTED DIFFUSER BLADES. Arthur W. Goldstein and Ralph L. Schacht. March 1955. 32p. diagrs., photo. (NACA RM E54L29)

Experimentally determined characteristics are described for a stage consisting of a rotor with supersonic relative velocities and a stator having swept and tilted blades over a range of equivalent tip speeds from 740 to 1702 ft/sec in air. Measurements were made of static-pressure distributions, overall performance, and of the magnitude, frequency, and rotative speed of pressure fluctuations, which were found to be very large and which are believed to have prevented the stator from attaining the flow configuration for which it was designed.

NACA RM E55K21

QUALITATIVE STUDY OF FLOW CHARACTERISTICS THROUGH SINGLE-STAGE TURBINES AS MADE FROM ROTOR-EXIT SURVEYS. Robert Y. Wong, James W. Miser, and Warner L. Stewart. March 1956. 26p. diagrs. (NACA RM E55K21)

The flow characteristics through a single-stage turbine can be deduced from survey results taken at the rotor exit. Some of the major factors that influence the measured flow patterns may be qualitatively isolated, thus facilitating their analysis. The survey results of two similar transonic turbines, both with relatively high diffusion on different surfaces of the rotor blade, indicate considerable circumferential variation in the momentum in the regions of free-stream flow out of the stator. At the rotor exit, angular momentum and total-pressure loss varied radially.

CRITERIA FOR INITIAL FLOW REVERSAL IN SYMMETRICAL TWIN-INTAKE AIR-INDUCTION SYSTEMS OPERATING AT SUPERSONIC SPEEDS. Andrew Beke. February 1956. 17p. diagrs. (NACA RM E55L02a)

Asymmetric flow and initial flow reversal of supersonic twin-intake air-induction systems can be predicted satisfactorily. Observations of conditions at decreased air flows in several typical supersonic twin air intakes having generally the same static-pressure recovery characteristics indicated that initial flow reversal (that is, zero flow in one duct) occurred simultaneously with critical inlet flow in the other duct. Consequently, with such inlets engine air flow cannot be reduced to less than half the total inlet critical air flow before initial flow reversal occurs.

NACA RM E56C06

FABRICATION TECHNIQUES AND HEAT-TRANSFER RESULTS FOR CAST-CORED AIR-COOLED TURBINE BLADES. John C. Freche and Robert E. Oldrieve. June 1956. 35p. diagrs., photos. (NACA RM E56C06)

Techniques were developed for casting air-cooled blades with a large number of relatively small cooling passages near the airfoil surface; two such blades of HS-21 material were run in a turbojet engine modified for air cooling. One blade was operated without failure for 78 hours at a centrifugal stress of 42,150 psi and an average inlet gas temperature of 1,735° F. Of this total, 50 hours were obtained at a coolant-to-gas flow ratio of 0.015 and 28 hours at a flow ratio of 0.004.

NACA RM E56I04

THEORETICAL ANALYSIS OF TOTAL-PRESSURE LOSS AND AIRFLOW DISTRIBUTION FOR TUBULAR TURBOJET COMBUSTORS WITH CONSTANT ANNULUS AND LINER CROSS-SECTIONAL AREAS. Charles C. Graves and Jack S. Grobman. January 1957. 85p. diagrs., tab. (NACA RM E56I04)

Generalized curves showing the combustor total-pressure-loss coefficient and liner air-flow distribution for various geometric configurations and operating conditions were obtained from compressible- and incompressible-flow calculations. The calculations include the effects of heat release, annulus wall friction, and variation in discharge coefficient of liner wall openings along the combustor. The results pertain to tubular turbojet combustors having (1) constant annulus and liner cross-sectional areas along the combustor axis and (2) flush circular holes in the liner wall.

NACA RM E56J22

PERFORMANCE OF AN EXPERIMENTAL ANNULAR TURBOJET COMBUSTOR WITH METHANE AND PROPANE. Carl T. Norgren. January 1957. 27p. diagrs., tabs. (NACA RM E56J22)

Combustion efficiencies obtained with gaseous methane were compared with reported data obtained with gaseous propane for the same experimental combustor configuration. The combustion efficiencies obtained with methane were 98, 91, and 77 percent at simulated flight altitudes of 56,000, 70,000, and 80,000 feet, corresponding to combustor inlet-air pressures from 15 to 5 inches of mercury absolute. Combustion efficiencies with propane were equivalent to those with methane up to a simulated altitude of 70,000 feet. At the most severe conditions investigated propane operated with a higher efficiency and over a wider range of fuel-air ratio than methane.

NACA RM E57C15

EXPERIMENTAL INVESTIGATION OF MODIFIED CAST-CORED BLADES HAVING HOLLOW TIP SECTIONS. Robert E. Oldrieve and John C. Freche. June 1957. 36p. diagrs., photos., (NACA RM E57C15)

Two modified cast-cored blades, 11 percent lighter than a fully cored blade, were experimentally investigated in a turbojet engine modified for air-cooling. One blade had 37 (0.060-in.) passages and the other 20 oval (0.100- by 0.060-in.) passages located near the airfoil surface. Both blades were hollow from 9/16 span to the tip. Fabrication techniques are presented. Generally, the 37-hole blade cooled more effectively than the 20-hole blade and showed a lower cooling-air pressure drop.

NACA RM E57D24

SURVEY OF HYDROGEN COMBUSTION PROPERTIES. Isadore L. Drell and Frank E. Belles. July 1957. (ii), 86p. diagrs., tabs. (NACA RM E57D24)

This literature digest of hydrogen-air combustion fundamentals presents data on flame temperature, burning velocity, quenching distance, flammability limits, ignition energy, flame stability, detonation, spontaneous ignition, and explosion limits. The data are assessed, recommended values are given, and relations among various combustion properties are discussed. New material presented includes: theoretical treatment of variation in spontaneous-ignition lag with temperature, pressure, and composition, based on reaction kinetics of hydrogen oxidation; and calculated adiabatic flame temperatures over the entire hydrogen-air composition range for 0.01 to 100 atmospheres and initial temperatures of 0° to 1400° K.

SUMMARY OF SPIN AND RECOVERY CHARACTERISTICS OF 12 MODELS OF FLYING-WING AND UNCONVENTIONAL-TYPE AIRPLANES. Ralph W. Stone, Jr., and Burton E. Hultz. March 1, 1951. 95p. diagrs., photo., tabs. (NACA RM L50L29)

The free-spinning model results of investigations of the spin and recovery characteristics of 12 flying-wing and unconventional-type designs have been summarized. Dimensional data, mass data, and three-view drawings of the 12 designs are presented. The model test results presented include the spin and recovery characteristics of each model for various combinations of control deflections and for various loading and dimensional configurations.

NACA RM L51L10a

LONGITUDINAL AERODYNAMIC CHARACTERISTICS OF MODEL AIRPLANE CONFIGURATION EQUIPPED WITH A SCALED X-1 AIRPLANE WING. James H. Parks. April 1952. 37p. diagrs. (NACA RM L51L10a)

A rocket-propelled model of an airplane-like configuration having a scaled X-1 wing, 8 percent thick, was flight tested at Reynolds numbers ranging from 2×10^6 to 4×10^6. Aerodynamic derivatives defining the static and dynamic longitudinal stability, control, trim, and drag characteristics of the configuration were obtained over a Mach number range from 0.6 to 1.17. Buffeting and maximum lift information were obtained at subsonic speeds. Some separate aerodynamic effects of the wing on the configuration were determined.

NACA RM L52L04

LONGITUDINAL STABILITY, CONTROL EFFECTIVENESS, AND DRAG CHARACTERISTICS AT TRANSONIC SPEEDS OF A ROCKET-PROPELLED MODEL OF AN AIRPLANE CONFIGURATION HAVING AN UNSWEPT TAPERED WING OF ASPECT RATIO 3.0 AND NACA 65A004.5 AIRFOIL SECTIONS. John C. McFall, Jr., and James A. Hollinger. January 1953. 30p. diagrs., photos. (NACA RM L52L04)

A flight investigation was conducted on a rocket-propelled airplane model having an unswept wing of aspect ratio 3.0 with NACA 65A004.5 airfoil sections. The longitudinal stability, control effectiveness, and drag characteristics of the configuration were determined over a Mach number range of 0.73 to 1.33 and compared with data from similar models having hexagonal airfoil sections.

NACA RM L52L08

STABILITY OF BODIES OF REVOLUTION HAVING FINENESS RATIOS SMALLER THAN 1.0 AND HAVING ROUNDED FRONTS AND BLUNT BASES. Stanley H. Scher and James S. Bowman, Jr. January 1953. 23p. diagrs., tabs. (NACA RM L52L08)

An investigation has been made of the stability of several bodies of revolution having fineness ratios smaller than 1.0 and having rounded fronts and blunt bases. Free-drop tests were made in the vertical Langley 20-foot free-spinning tunnel to determine the behavior of the various bodies in descent, and a method was developed for calculating approximately the stability of bodies of the subject type.

NACA RM L53F29

TRANSONIC FLIGHT MEASUREMENT OF THE AERODYNAMIC LOAD ON THE EXTENDED SLAT OF THE DOUGLAS D-558-II RESEARCH AIRPLANE. James R. Peele. August 1953. 34p. diagrs., photos., tab. (NACA RM L53F29)

The results of transonic flight measurements of the aerodynamic load encountered over a partial-span leading-edge slat on the 35° sweptback wing of the Douglas D-558-II research airplane are presented for the lift range at Mach numbers from 0.45 to 0.98.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53L17

AERODYNAMIC CHARACTERISTICS OF A FULL-SPAN TRAILING-EDGE CONTROL ON A 60° DELTA WING WITH AND WITHOUT A SPOILER AT MACH NUMBER 1.61. Douglas R. Lord and K. R. Czarnecki. March 1954. 49p. diagrs., photos., tab. (NACA RM L53L17)

An investigation has been made at a Mach number of 1.61 and a Reynolds number of 4.2×10^6 to determine the aerodynamic characteristics of a full-span trailing-edge control on a 60° delta wing with and without a partial-span spoiler mounted on the wing just ahead of the control. Tests were made over an angle-of-attack range from 0° to 15° and a control deflection range from -30° to 30°. A few illustrative pressure distributions are presented, and the control effectiveness and hinge-moment-coefficient variations for the basic wing-control configuration are compared with those predicted by linear theory and those obtained from the spoiler configurations.

NACA RM L53L18

LOW-SPEED CHORDWISE PRESSURE DISTRIBUTIONS NEAR THE MIDSPAN STATION OF THE SLOTTED FLAP AND AILERON OF A 1/4-SCALE MODEL OF THE BELL X-1 AIRPLANE WITH A 4-PERCENT-THICK, ASPECT-RATIO-4, UNSWEPT WING. William C. Moseley, Jr., and Robert T. Taylor. March 1954. 59p. diagrs., photos., tabs. (NACA RM L53L18)

An investigation was made to determine the chordwise pressure distribution at two spanwise stations on a 4-percent-thick, aspect-ratio-4, unswept wing of a 1/4-scale model of the Bell X-1 airplane. These pressure stations were selected to give typical pressure distributions across the slotted flap and aileron of the model.

NACA RM L53L24a

EFFECT OF SOME SECTION MODIFICATIONS AND PROTUBERANCES ON THE ZERO-LIFT DRAG OF DELTA WINGS AT TRANSONIC AND SUPERSONIC SPEEDS. Carl A. Sandahl and William E. Stoney. February 1954. 43p. diagrs., photos., tabs. (NACA RM L53L24a)

An investigation was made to determine the effects on the zero-lift drag of a 60° delta wing of some section modifications fore and aft of the position of maximum thickness. In addition, one configuration employed simulated control-actuator housings. For the subsonic leading-edge condition of the tests, leading-edge radius had no effect on the drag coefficient. Some thickening of the airfoil aftersection resulted in a slight increase in drag coefficient as long as the trailing-edge thickness was zero. At supersonic speeds, the drag coefficient varied nearly linearly with those values of trailing-edge thickness tested. Increasing the section thickness ratio from 0.03 to 0.06 near the wing tip resulted in no increment in drag coefficient. Linear theory generally predicted larger values of wing pressure drag coefficient than those obtained experimentally, but predicted effects of section changes accurately.

NACA RM L54L17a

FREE-FLIGHT INVESTIGATION TO DETERMINE SOME EFFECTS OF TAIL DAMPING AND WING-TAIL INTERFERENCE ON THE ROLLING EFFECTIVENESS OF INBOARD AND OUTBOARD AILERONS ON AN UNTAPERED SWEPTBACK WING. Roland D. English. March 1955. 18p. diagrs., photos. (NACA RM L54L17a)

An investigation has been made to determine some effects of tail damping and wing-tail interference on the rolling effectiveness of inboard and outboard ailerons on sweptback wings. The results of the investigation indicate that the substitution of fixed tail fins for a free-to-roll tail on a wing-body combination reduced the rolling effectiveness of an inboard aileron considerably over the entire test Mach number range (0.6 to 1.5) but caused no consistent change in the rolling effectiveness of an outboard aileron.

NACA RM L54L20

INVESTIGATION OF THE LATERAL STABILITY CHARACTERISTICS OF THE DOUGLAS X-3 CONFIGURATION AT MACH NUMBERS FROM 0.6 TO 1.1 BY MEANS OF A ROCKET-PROPELLED MODEL. Jesse L. Mitchell and Robert F. Peck. February 1955. 37p. diagrs., photo., tabs. (NACA RM L54L20)

A rocket-propelled model of the Douglas X-3 airplane was flown in the Mach number range from 0.6 to 1.1 to obtain lateral stability data from the response to pulse-type disturbances. The model was, in general, statically and dynamically stable throughout the Mach number range of the test; however, there was some evidence of neutral dynamic stability at small angles of sideslip. A vector-analysis procedure was used to obtain some of the lateral stability derivatives. Comparisons made with other data indicate fair to good agreement.

NACA RM L54L29

AN ANALYSIS OF THE TRANSONIC AND SUPERSONIC PERFORMANCE OF SEVERAL FIXED-GEOMETRY AIR INLETS. Robert E. Pendley and Robert R. Howell. March 1955. 36p. diagrs., tab. (NACA RM L54L29)

An analysis has been made of the influence of several factors on the magnitude of the deviation of the maximum power performance of several fixed-geometry inlets from ideal values. Experimentally determined drag and total-pressure recovery characteristics were used in calculating the performance variations. Generally, it was shown that, when properly sized,

DECLASSIFIED NACA RESEARCH REPORTS

the performance of a fixed-geometry inlet is very near optimum over a broad range of operating conditions. It was also shown that the performance of the inlet is greatly affected by the rate of increase in engine air-flow requirements with Mach number.

NACA RM L55I23a

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF A MODEL HAVING CROPPED-DELTA AND UNSWEPT WING PLAN FORMS AND SEVERAL TAIL CONFIGURATIONS. Albert G. Few, Jr. November 1955. 107p. diagrs., photo., tab. (NACA RM L55I23a)

The present paper presents some effects of horizontal-tail length and tail configuration on the high subsonic static longitudinal stability characteristics of a complete model having thin cropped-delta and unswept wings of aspect ratio 3 and taper ratios of 0.14 and 0.20, respectively. The model was tested with a high T-tail (mounted on the vertical tail), a low tail (on the wing chord extended), and with "a bitail" consisting of the combination of the high and low tails. The Mach number range was from about 0.80 to 0.92 which corresponds to Reynolds numbers ranging from about 4.0×10^6 to 4.2×10^6 for average test conditions.

NACA RM L55L09

LONGITUDINAL STABILITY INVESTIGATION FOR A MACH NUMBER RANGE OF 0.8 TO 1.7 OF AN AIRPLANE CONFIGURATION WITH A 45° SWEPT WING AND A LOW HORIZONTAL TAIL. John C. McFall, Jr. February 1956. 32p. diagrs., photos., tab. (NACA RM L55L09)

A flight investigation has been conducted on a rocket-boosted airplane model having a 45° swept wing of aspect ratio 4.0, taper ratio 0.3, and NACA 65A006 airfoil section. The configuration had a swept empennage with a low horizontal tail. Longitudinal stability and drag characteristics were determined over a Mach number range of 0.8 to 1.7.

NACA RM L55L12

AERODYNAMIC LOADINGS ASSOCIATED WITH SWEPT AND UNSWEPT SPOILERS ON A FLAT PLATE AT MACH NUMBERS OF 1.61 AND 2.01. Douglas R. Lord and K. R. Czarnecki. March 1956. 174p. diagrs., photos., tabs. (NACA RM L55L12)

An investigation has been made at Mach numbers of 1.61 and 2.01 for a range of Reynolds numbers from 0.12×10^6 to 0.56×10^6 per inch to examine the flow, force, and moment characteristics associated with spoilers mounted on a flat plate at sweep angles from 0° to 75°. For the unswept condition, the spoiler characteristics could be correlated for a given Mach number on the basis of the height and location of the spoiler top. The three-dimensional behavior of the flow over the swept spoilers and the limited data available precluded the establishment of any simple method for extending the unswept-spoiler results to the swept case. Regions of reversal in lift effectiveness and large decreases in pitching moment were observed near the spoiler apex for the swept spoilers; whereas the section drag and hinge moment decreased as distance from the apex increased.

NACA RM L55L14a

SUPERSONIC WAVE INTERFERENCE AFFECTING STABILITY. Eugene S. Love. March 1956. 19p. diagrs., photos. (NACA RM L55L14a)

Some of the significant interference fields that may affect stability of aircraft at supersonic speeds are briefly summarized. Illustrations and calculations are presented to indicate the importance of interference fields created by wings, bodies, wing-body combinations, jets, and nacelles.

NACA RM L55L20

SOME EFFECTS OF AILERONS ON THE VARIATION OF AERODYNAMIC CHARACTERISTICS WITH SIDESLIP AT LOW SPEED. Kenneth W. Goodson. March 1956. 40p. diagrs., tab. (NACA RM L55L20)

Results are presented of an investigation to determine the effects of aileron deflection on the low-speed aerodynamic characteristics of a typical high-speed airplane model in sideslip. Some data are presented for the model with inboard, outboard, and combined inboard-outboard ailerons on a 45° swept-back wing.

NACA RM L55L21

A FREE-FLIGHT INVESTIGATION OF THE EFFECTS OF A SONIC JET ON THE TOTAL-DRAG AND BASE-PRESSURE COEFFICIENTS OF A BOAT-TAIL BODY OF REVOLUTION FROM MACH NUMBER 0.83 TO 1.70. Ralph A. Falanga. March 1956. 18p. diagrs., photo., tab. (NACA RM L55L21)

Two 7.5° conical boattail bodies of revolution with constant base annuli and varying jet static-pressure ratios and with simulated-turbojet exhaust rocket motors were flight-tested to determine the jet interference effects on drag and base-pressure coefficients over a Mach number range from approximately 0.83 to 1.70. It was found that for jet static-pressure ratios of 1.83 to 2.40, the total power-on drag coefficients were lower than the corresponding power-off values throughout power-on test Mach number range. Power-on base-pressure coefficients were reduced with a reduction of jet static-pressure ratios and also with increasing supersonic Mach numbers.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L55L21a

LOW-SPEED STATIC STABILITY CHARACTERISTICS OF A CAMBERED-DELTA-WING MODEL. John M. Riebe and William C. Moseley, Jr. March 1956. 27p. diagrs. (NACA RM L55L21a)

The present paper presents the results of an investigation in the Langley 300 MPH 7- by 10-foot tunnel to determine the stability characteristics of a cambered 60° delta-wing configuration. Tests were made at several wing dihedral angles in combination with a circular fuselage and various tail configurations. Proper selection of V-tails which were investigated with the 20° and 50° wing dihedral angles resulted in model configurations which had longitudinal and directional stability throughout the lift-coefficient range.

NACA RM L55L23a

SPINNING AND RELATED PROBLEMS AT HIGH ANGLES OF ATTACK FOR HIGH-SPEED AIRPLANES. Walter J. Klinar. March 1956. 8p. diagrs. (NACA RM L55L23a)

A discussion is presented of the type of control manipulation and various techniques that may be required for satisfactory spin recovery of contemporary fighter designs. The effects in spins of jet-engine installations and the effectiveness of canard surfaces in alleviating a directional divergence near the stall and subsequent spin entry on one configuration are also discussed.

NACA RM L55L26a

EFFECTS OF WING-BODY GEOMETRY ON THE LATERAL-FLOW ANGULARITIES AT SUBSONIC SPEEDS. Frank S. Malvestuto, Jr., and William J. Alford, Jr. February 1956. 15p. diagrs. (NACA RM L55L26a)

The lateral flow characteristics along a vertical tail station have been investigated experimentally and theoretically at low subsonic speeds. The effects of changes in wing-body geometry such as nose-position and shape, fuselage cross-sectional shape, and wing vertical height are described. The theoretical model which represented separated flow phenomena by a simple vortex model is described in an appendix.

NACA RM L55L28

EXPERIMENTAL RESULTS FROM A TEST IN ROUGH AIR AT HIGH SUBSONIC SPEEDS OF A TAILLESS ROCKET MODEL HAVING CRUCIFORM TRIANGULAR WINGS, AND A NOTE ON THE CALCULATION OF MEAN SQUARE LOADS OF AIRCRAFT IN CONTINUOUS ROUGH AIR. A. James Vitale and Jesse L. Mitchell. April 1956. 25p. diagrs., photo., tab. (NACA RM L55L28)

Flight tests in continuous rough air at transonic speeds have been made of a tailless rocket model having cruciform 60° triangular wings. The variation of root-mean-square acceleration with Mach number is presented. The cruciform-wing arrangement is evaluated as a means of improving rocket-propelled-model rough-air tests. A simplified chart, based on power-spectral methods of generalized harmonic analysis, is presented which permits a rapid estimation of the mean square acceleration of aircraft for flight through continuous rough air.

NACA RM L55L29

RESULTS OF ROCKET MODEL TEST OF AN AIRPLANE CONFIGURATION HAVING AN ARROW WING AND SLENDER FLAT-SIDED FUSELAGE. LIFT, DRAG, LONGITUDINAL STABILITY, LATERAL FORCE, AND JET EFFECTS AT MACH NUMBERS BETWEEN 1.0 AND 2.3. Robert F. Peck. February 1956. 26p. diagrs., photo. (NACA RM L55L29)

A rocket-propelled model of an airplane configuration having an arrow wing (with 55° leading-edge sweep) in combination with a slender, flat-sided fuselage mounting swept horizontal and vertical tails has been used by the Langley Pilotless Aircraft Research Division to investigate its aerodynamic characteristics at Mach numbers between 1.0 and 2.3 through use of the pulsed-control technique. Lift and stability data agreed well with theoretical estimates and jet-effects data were in agreement with expectations based on previous data.

NACA RM L55L30

EFFECTS OF LEADING-EDGE RADIUS ON THE LONGITUDINAL STABILITY CHARACTERISTICS OF TWO 60° SWEPTBACK WINGS AT HIGH REYNOLDS NUMBERS. William C. Schneider. March 1956. 46p. diagrs. (NACA RM L55L30)

Force-test data showing the effects of changes in leading-edge radius, aspect ratio, Reynolds number, and Mach number are presented for a 60° sweptback wing. Data are presented for leading-edge radii of 0.89 and 1.30 percent chord, aspect ratios of 2 and 3, Reynolds numbers up to 10.40×10^{6}, and Mach numbers up to 0.30. These data are a continuation of the data presented in NACA RM L55F06 and RM L55H04.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L55L30a

LOW-SPEED INVESTIGATION OF THE EFFECTS OF WING DIHEDRAL ANGLE AND FIN LENGTH ON THE STATIC STABILITY CHARACTERISTICS OF A MODEL HAVING AN 82° DELTA WING. Kenneth P. Spreemann. April 1956. 30p. diagrs. (NACA RM L55L30a)

An investigation was conducted in the Langley 300 MPH 7- by 10-foot tunnel at dynamic pressures of 40 and 60 pounds per square foot and corresponding Reynolds numbers of 6.09×10^6 and 7.42×10^6, based on the mean aerodynamic chord, to determine the effects of changes in wing dihedral angle and length and position of fins on the static stability characteristics of an 82° delta-wing—body configuration. Wing dihedral angles of 0° and ±30° and three fins of different lengths mounted above and below the fuselage were investigated.

NACA RM L57C14

SOME EFFECTS OF HEAT TRANSFER AT MACH NUMBER 2.0 AT STAGNATION TEMPERATURES BETWEEN 2,310° AND 3,500° R ON A MAGNESIUM FIN WITH SEVERAL LEADING-EDGE MODIFICATIONS. William M. Bland, Jr., and Walter E. Bressette. April 1957. 29p. diagrs., photos., tab. (NACA RM L57C14)

Four models of a thin magnesium fin, with the leading edge swept back 35°, have been tested in the preflight high-temperature jet of the Langley Pilotless Aircraft Research Station at Wallops Island, Va., at a Mach number of 2.0 for various stagnation temperatures between 2,310° and 3,500° R. This exploratory investigation was made to determine some effects of aerodynamic heating at high stagnation temperatures on the leading edges of fins and to determine the relative effectiveness of several leading-edge protective schemes.

Research Abstracts and Reclassification Notice

REC'D FEB 13 1958

NO. 124 **FEBRUARY 10, 1958**

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1302

ON PANEL FLUTTER AND DIVERGENCE OF INFINITELY LONG UNSTIFFENED AND RING-STIFFENED THIN-WALLED CIRCULAR CYLINDERS. Robert W. Leonard and John M. Hedgepeth. 1957. ii, 19p. diagrs. (NACA Rept. 1302. Supersedes TN 3638)

A preliminary theoretical investigation of the panel flutter and divergence of infinitely long, unstiffened and ring-stiffened thin-walled circular cylinders is described. Analytical criteria for the location of stability boundaries are presented along with a limited number of computed results.

NACA Rept. 1304

FLIGHT INVESTIGATION OF THE EFFECTIVENESS OF AN AUTOMATIC AILERON TRIM CONTROL DEVICE FOR PERSONAL AIRPLANES. William H. Phillips, Helmut A. Kuehnel, and James B. Whitten. 1957. ii, 15p. diagrs., photos. (NACA Rept. 1304. Supersedes TN 3637)

An analytical and flight investigation has been made to determine the effectiveness of an automatic aileron trim control device in conjunction with preloaded aileron centering springs in improving spiral stability characteristics of a personal airplane. The results indicate that the device can maintain the airplane in level flight under instrument conditions despite disturbances due to moderate turbulence or trim changes with airspeed and flight condition.

NACA Rept. 1310

AN INVESTIGATION OF FOUR WINGS OF SQUARE PLAN FORM AT A MACH NUMBER OF 6.9 IN THE LANGLEY 11-INCH HYPERSONIC TUNNEL. Charles H. McLellan, Mitchel H. Bertram, and John A. Moore. 1957. ii, 18p. diagrs., photos. (NACA Rept. 1310. Supersedes RM L51D17)

The results of tests of four wings at a Mach number of about 6.86 and a Reynolds number of 0.98×10^6 are presented. The wings had square plan forms with 5-percent-thick diamond, half-diamond, wedge, and half-circular-arc sections. The boundary layer was found to have a large effect on the pressure distributions. Reasonable agreement was indicated between the aerodynamic coefficients from experimental pressure data and inviscid theory. Total-drag measurements showed good agreement with the theory at low angles of attack when the effects of surface friction were included. At the higher angles of attack, both lift coefficient and drag coefficient were slightly below the values predicted by the two-dimensional theory.

NACA Rept. 1311

DETERMINATION OF VORTEX PATHS BY SERIES EXPANSION TECHNIQUE WITH APPLICATION TO CRUCIFORM WINGS. Alberta Y. Alksne. 1957. iii, 13p. diagrs., photos. (NACA Rept. 1311. Supersedes TN 3670)

A series method is applied to the computation of vortex positions behind a slender equal-span cruciform wing at any angle of bank as a function of the distance behind the trailing edge. Calculated paths are compared with the results of water-tank experiments and of a closed expression given in NACA TN 2605. The forces on an equal-span interdigitated cruciform tail behind a slender equal-span cruciform wing are calculated for five angles of bank from the vortex positions found by use of the series.

NACA Rept. 1312

SOME EFFECTS OF BLUNTNESS ON BOUNDARY-LAYER TRANSITION AND HEAT TRANSFER AT SUPERSONIC SPEEDS. W. E. Moeckel. 1957. ii, 14p. diagrs. (NACA Rept. 1312. Supersedes TN 3653)

Large downstream movements of transition observed when the leading edges of a hollow cylinder or a flat plate are slightly blunted are explained in terms of the reduction in Reynolds number at the outer edge of the boundary layer due to the detached shock wave. This Reynolds number reduction leads to a predicted downstream movement of transition which is in good agreement with the hollow-cylinder result at Mach 3.1. Application of this theory to other Mach numbers yields the result that blunting the tip of slender cones or the leading edge of thin wedges should produce downstream movements of transition by factors ranging from 2 at Mach number 3.0 to 30 at Mach number 15.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1313

EXPLORATORY INVESTIGATION OF BOUNDARY-LAYER TRANSITION ON A HOLLOW CYLINDER AT A MACH NUMBER OF 6.9. Mitchel H. Bertram. 1957. ii, 27p. diagrs., photos. (NACA Rept. 1313. Supersedes TN 3546)

The Reynolds number for transition on the outside of a hollow cylinder with heat transfer from the boundary layer to the wall has been investigated at a Mach number of 6.9 in the Langley 11-inch hypersonic tunnel. The type of boundary layer was determined from impact-pressure surveys and optical viewing. From a correlation of results obtained from various sources at lower Mach numbers (in the range 2.0 to 4.5) and data from the present tests with variable Reynolds number per inch, leading-edge thickness and free-stream Reynolds number per inch appear to be important considerations in flat-plate transition results. At a given Mach number, it appears that the Reynolds number based on leading-edge thickness is an important parameter that must be considered in comparisons of flat-plate transition data from various installations.

NACA Rept. 1315

ON SLENDER-BODY THEORY AT TRANSONIC SPEEDS. Keith C. Harder and E. B. Klunker. 1957. ii, 6p. (NACA Rept. 1315. Supersedes TN 3815)

The basic ideas of the slender-body approximation have been applied to the nonlinear transonic-flow equation for the velocity potential in order to obtain some of the essential features of slender-body theory at transonic speeds. The results of the investigation are presented from a unified point of view which demonstrates the similarity of slender-body solutions in the various Mach number ranges. The transonic area rule and some conditions concerning its validity follow from the analysis.

NACA Rept. 1316

TORSIONAL STIFFNESS OF THIN-WALLED SHELLS HAVING REINFORCING CORES AND RECTANGULAR, TRIANGULAR, OR DIAMOND CROSS SECTION. Harvey G. McComb, Jr. ii, 14p. diagrs. (NACA Rept. 1316. Supersedes TN 3749)

A theoretical investigation is presented of the torsional stiffness of thin-walled aerodynamic surfaces filled with cores which stabilize the skins. Rectangular, slender triangular, and slender diamond cross sections are considered. Results for the torsional stiffness constants are shown graphically.

NACA Rept. 1318

THREE-DIMENSIONAL TRANSONIC FLOW THEORY APPLIED TO SLENDER WINGS AND BODIES. Max. A. Heaslet and John R. Spreiter. 1957. iii, 29p. diagrs. (NACA Rept. 1318. Supersedes TN 3717)

Integral equations for transonic flow around slender wings and bodies are derived assuming shock waves are present. For sonic flow, Oswatitsch's equivalence rule is extended to lifting cases at small angles of attack. Relationships are presented between the pressure distributions and integrated forces on slender wings and bodies having the same longitudinal distribution of cross-section area. Specific application is made to slender cone-cylinders of elliptic cross sections of varying eccentricity. The conclusions are supported both by formal analysis of the order of the error terms and by comparison with existing theoretical and experimental information.

NACA RM L57J15

LOW-SPEED BOUNDARY-LAYER-CONTROL INVESTIGATION ON A THIN RECTANGULAR SEMI-SPAN WING WITH LEADING-EDGE AND TRAILING-EDGE FLAPS. Delwin R. Croom and Thomas R. Turner. January 1958. 213p. diagrs., tabs. (NACA RM L57J15)

Results are presented, without discussion, of a wind-tunnel investigation to determine the longitudinal aerodynamic characteristics and the chordwise load distribution on a thin, untapered, unswept wing having an aspect ratio of 3.33 and NACA 65A004 airfoil sections. The wing was equipped with leading-edge and trailing-edge flaps. Boundary-layer control was obtained by blowing air over the trailing-edge flaps.

NACA RM L57J17

EFFECTIVENESS OF VARIOUS PROTECTIVE COVERINGS ON MAGNESIUM FINS AT MACH NUMBER 2.0 AND STAGNATION TEMPERATURES UP TO 3,600° R. William M. Bland, Jr. January 1958. 48p. diagrs., photos., tab. (NACA RM L57J17)

Eight thin magnesium fins, seven with the leading edges swept back 17° and one with the leading edge swept back 45°, have been tested in the preflight high-temperature jet of the Langley Pilotless Aircraft Research Station at Wallops Island, Va. Protective coverings, designed to alleviate the effects of aerodynamic heating on fins used during the first stages of rocket-propelled multistage hypersonic models, have been applied to these fins. Temperatures measured at various locations on the fins indicated the effectiveness of the various coverings. Effective air gaps between the layers of material were calculated using simple heat-balance relations.

CURRENT NACA RESEARCH REPORTS

NACA TM 1431

ON THE STATISTICAL THEORY OF TURBULENCE. (Zur statistischen Theorie der Turbulenz). W. Heisenberg. January 1958. 36p. diagrs. (NACA TM 1431. Translation from Zeitschrift für Physik, v. 124, 1948, p. 628-657)

A study is made of the spectrum of isotropic turbulence with the aid of the customary method of Fourier analysis. The spectrum of the turbulent motion is derived to the smallest wave lengths, that is, into the laminar region, and correlation functions and pressure fluctuations are calculated. A comparison with experimental results is included. Finally, an attempt is made to derive the numerical value of a constant characteristic of the energy dissipation in isotropic turbulence.

NACA TN 3987

EFFECT OF ENVIRONMENTS OF SODIUM HYDROXIDE, AIR, AND ARGON ON THE STRESS-RUPTURE PROPERTIES OF NICKEL AT 1500° F. Howard T. McHenry and H. B. Probst. January 1958. 23p. diagrs., photos., tab. (NACA TN 3987)

Stress-rupture lives of nickel tubes both containing sodium hydroxide and devoid of sodium hydroxide were determined for testing environments of argon and air. Sodium hydroxide had no effect on the strength of nickel in argon. Severe intergranular and surface oxidation of nickel tubes tested in air increased their rupture strength over that of similar specimens tested in argon. This strengthening was partly lost when the tubes contained sodium hydroxide.

NACA TN 4069

EFFECT OF ANGLE OF ATTACK AND THICKNESS ON AERODYNAMIC COEFFICIENTS OF A RIGID WING OSCILLATING AT VERY LOW FREQUENCIES IN TWO-DIMENSIONAL SUPERSONIC FLOW. Frank S. Malvestuto, Jr., and Julia M. Goodwin. January 1958. 65p. diagrs. (NACA TN 4069)

Analytical expressions are presented for the effect of angle of attack and thickness on the lift and pitching-moment derivatives of a wing performing a plunging motion and rotary oscillations at very low frequencies in two-dimensional flow. Design charts are presented which permit rapid calculation of these coefficients. The results presented are for a range of Mach number, angle of attack, and thickness for which the flow behind the shock attached to the leading edge is everywhere supersonic, although the effect of viscous separation at finite angles of attack restricts the validity of the results to a much smaller range of these parameters.

NACA TN 4086

DISCRETE POTENTIAL THEORY FOR TWO-DIMENSIONAL LAPLACE AND POISSON DIFFERENCE EQUATIONS. Charles Saltzer, Case Institute of Technology. January 1958. 60p. diagrs., tabs. (NACA TN 4086)

A method is given for solving problems associated with Laplace and Poisson equations which, in general, requires considerably fewer equations than the usual methods and which gives a convergent solution by the method of successive approximations.

NACA TN 4109

LOW-SPEED YAWED-ROLLING CHARACTERISTICS AND OTHER ELASTIC PROPERTIES OF A PAIR OF 40-INCH-DIAMETER, 14-PLY-RATING, TYPE VII AIRCRAFT TIRES. Walter B. Horne and Robert F. Smiley. January 1958. 80p. diagrs., photos., tabs. (NACA TN 4109)

The low-speed cornering characteristics of the tires under yawed rolling were determined over a range of inflation pressures and yaw angles for two vertical loads. Static tests were also performed to determine the tire vertical, lateral, torsional, and fore-and-aft elastic characteristics. The quantities measured included lateral or cornering force, drag force, twisting moment or self-alining torque, pneumatic caster, vertical and lateral tire deflections, wheel torsion or yaw angle, rolling radius, and relaxation length.

NACA TN 4110

MECHANICAL PROPERTIES OF PNEUMATIC TIRES WITH SPECIAL REFERENCE TO MODERN AIRCRAFT TIRES. Robert F. Smiley and Walter B. Horne. January 1958. 166p. diagrs., photo., tabs. (NACA TN 4110)

A study is presented of most of the properties of pneumatic tires which are of interest to aircraft designers. The principal topics discussed are tire vertical-force-deflection characteristics; lateral, fore-and-aft, and torsional spring constants; footprint-area properties; relaxation lengths; rolling radius; cornering force, cornering power, self-alining torque, and pneumatic caster for yawed rolling conditions; effects of wheel tilt; and tire radial growth under the influence of centrifugal forces. For each tire property considered, semiempirical equations are set up which take into account the major factors pertinent to the property. Wherever possible each equation is compared with the available experimental data to establish its degree of reliability.

CURRENT NACA RESEARCH REPORTS

NACA TN 4118

LOW-TEMPERATURE, VAPOR-PHASE OXIDATION OF FUEL-RICH HYDROCARBON MIXTURES. William T. House and Milton Orchin, University of Cincinnati. January 1958. 30p. diagrs., tabs. (NACA TN 4118)

The vapor-phase oxidation of methylcyclohexane was studied in a flow system in the temperature range of 300° to 400° C under the conditions of 0.1 the stoichiometric amount of oxygen, a contact time of 8 seconds, and a spiral Pyrex reactor 10.5 inches long with an inside diameter of 3/32 inch. The yields of acids, aldehydes, ketones, hydrogen peroxide, organic peroxides, olefin, water, and unreacted hydrocarbon were determined in the products.

NACA TN 4120

THEORETICAL CALCULATIONS OF SUPERSONIC WAVE DRAG AT ZERO LIFT FOR A PARTICULAR STORE ARRANGEMENT. Kenneth Margolis, Frank S. Malvestuto, Jr., and Peter J. Maxie, Jr. January 1958. 37p. diagrs., tab. (NACA TN 4120)

A linearized-theory analysis of the wave drag at zero lift is carried out for a simple two-body arrangement consisting of two wedgelike surfaces, each with a rhombic lateral cross section and emanating from a common apex. Such an arrangement could be used as two stores, either embedded within or mounted below a wing, or as auxiliary bodies wherein the upper halves could be used as stores and the lower halves for bomb or missile purposes. Consideration is also given the case of two similar bodies in a parallel arrangement. The calculations encompass the complete range of supersonic speeds.

NACA TN 4126

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF SOME SHROUD DESIGN VARIABLES ON THE STATIC THRUST CHARACTERISTICS OF A SMALL-SCALE SHROUDED PROPELLER SUBMERGED IN A WING. Robert T. Taylor. January 1958. 23p. diagrs., photos. (NACA TN 4126)

An experimental investigation has been made to determine the effects of shroud-lip radius, shroud length, and shroud diffuser angle on the static thrust characteristics of a small-scale shrouded propeller submerged in the wing of an airplane. The relatively short shrouds necessary with this type of installation do not seem to affect adversely the static thrust characteristics of the shrouded propeller. The important variables were found to be shroud-lip radius and distance of the shroud exit from the ground.

NACA TN 4137

FATIGUE BEHAVIOR OF AIRCRAFT STRUCTURAL BEAMS. W. S. Hyler, H. G. Popp, D. N. Gideon, S. A. Gordon, and H. J. Grover, Battelle Memorial Institute. January 1958. 60p. diagrs., photos., tabs. (NACA TN 4137)

This investigation involved a study of the correlation of composite structural fatigue behavior, basic material, and simple-element behavior. Fatigue and related static tests were made on aluminum-alloy box beams and I-beams and also on elements simulating key failure locations in the two beams.

NACA TN 4144

EFFECT OF OXYGEN RECOMBINATION ON ONE-DIMENSIONAL FLOW AT HIGH MACH NUMBERS. Steve P. Heims. January 1958. 52p. diagrs. (NACA TN 4144)

A theoretical analysis of air flow in a stream tube, in which oxygen dissociation and recombination occur, has been made. The theory developed permits a finite reaction rate which varies from point to point along the flow. An estimate of the rate of reaction is made and a numerical example is worked out for a stream tube with a shape that might be expected for air flowing around a blunt body.

NACA TN 4146

CONTRIBUTION OF THE WING PANELS TO THE FORCES AND MOMENTS OF SUPERSONIC WING-BODY COMBINATIONS AT COMBINED ANGLES. J. Richard Spahr. January 1958. 62p. diagrs., photo., tabs. (NACA TN 4146)

A wind-tunnel investigation was made at a Mach number of 1.96 to determine the normal forces, pitching moments, and rolling moments contributed by each wing panel of a cruciform-wing and body combination over a wide range of combined angles of pitch and roll. The wings were triangular of aspect ratio 2, and the body was an ogive-cylinder combination. The effect on these characteristics of forebody length and roughness, Reynolds number, and panel-panel interference was investigated. A general theoretical method was developed which provided a satisfactory prediction of the panel results.

NACA TN 4148

THEORETICAL PRESSURE DISTRIBUTIONS FOR SEVERAL RELATED NONLIFTING AIRFOILS AT HIGH SUBSONIC SPEEDS. John R. Spreiter, Alberta Y. Alksne, and B. Jeanne Hyett. January 1958. (i), 52p. diagrs., tab. (NACA TN 4148)

Five related airfoils, including thin circular-arc airfoils, are considered. These airfoils have various locations for the point of maximum thickness

CURRENT NACA RESEARCH REPORTS

ranging from 30- to 70-percent chord and are of arbitrary, although small, thickness ratio. The results are obtained by approximate solution, through an iteration process, of a nonlinear integral equation derived from the equations of transonic flow theory. It is shown that the pressure distributions display most of the principal phenomena observed in experimental studies, and are in good correspondence with those calculated by other methods for subcritical Mach numbers and for Mach numbers near 1.

NACA TN 4157

CORROSION RESISTANCE OF NICKEL ALLOYS IN MOLTEN SODIUM HYDROXIDE. H. B. Probst, C. E. May, and Howard T. McHenry. January 1958. 26p. diagr., photos., tabs. (NACA TN 4157)

Corrosion resistance of 11 materials at 1500° and 1700° F was compared with the excellent corrosion-resistant properties of pure nickel. The materials were noncommercial solid-solution alloys and two-phase materials. The latter were strengthened either by precipitation or mechanical dispersion of small particles. Intergranular attack in these materials was considerably less than that reported for commercial nickel-base alloys. The Ni + 30 percent Cu alloy exhibited resistance to corrosion comparable with that of pure nickel; other materials (Ni+Mo, Ni+Zr, Ni+Sn, Ni+TiC, Ni+MgO, and Ni+Al_2O_3) appeared promising.

NACA TN 4159

EXPERIMENTAL INVESTIGATION OF TURBOJET-ENGINE MULTIPLE-LOOP CONTROLS FOR NON-AFTERBURNING AND AFTERBURNING MODES OF ENGINE OPERATION. Donald B. Kirsch, Leon M. Wenzel, and Clint E. Hart. January 1958. 61p. diagrs., tab. (NACA TN 4159)

Multiple-loop controls optimized rotor speed and turbine-discharge temperature transients during thrust increase and afterburner ignition by manipulation of engine fuel flow and exhaust-nozzle area. Good engine transient performance characteristics were obtained with a control system in which engine speed was controlled by manipulation of exhaust-nozzle area and turbine-discharge temperature by engine fuel flow. Acceptable although more oscillatory transient responses were obtained with a control system in which speed was controlled by manipulation of engine fuel flow, turbine-discharge temperature was controlled by manipulation of exhaust-nozzle area, and a noninteraction gain term was incorporated from the speed- to the temperature-control loops.

NACA TN 4163

EFFECT OF TEMPERATURE ON ROLLING-CONTACT FATIGUE LIFE WITH LIQUID AND DRY POWDER LUBRICANTS. Thomas L. Carter. January 1958. 40p. diagrs., photos., tabs. (NACA TN 4163)

The fatigue life of AISI M-1 tool steel was determined at temperatures of 100°, 250°, and 450° F with di(2-ethylhexyl)sebacate lubricant and at 450° F with dry powder lubricants. With the sebacate, lubricant life decreased with increasing temperature. At 100° F a suspension of molybdenum disulfide in polyalkylene gylcol produced a definite limit on fatigue life because of stress-corrosion penetration to the subsurface zone of high shear stress. The lowering of fatigue life with dry powder lubricants at 450° F appeared to be due to the lubricant particles acting as stress raisers localized in the bands of pure rolling within the contact zone.

NACA TN 4164

TWO-DIMENSIONAL DIFFUSION THEORY ANALYSIS OF REACTIVITY EFFECTS OF A FUEL-PLATE-REMOVAL EXPERIMENT. Edward R. Gotsky, James P. Cusick, and Donald Bogart. January 1958. 30p. diagrs., photos., tab. (NACA TN 4164)

Effects of fuel plates successively withdrawn from the center fuel element of a seven- by three-core loading at the Oak Ridge Bulk Shielding Facility were evaluated by two-dimensional two-group diffusion calculations performed on the NACA reactor simulator. Two calculation methods were used: (1) The slowing-down properties of the experimental fuel element were represented by infinite media parameters; and (2) the finite size of the experimental fuel element was recognized, and the slowing-down properties of the surrounding core were attributed to this small region. Reasonable agreement existed between experimental and calculated effects.

NACA TN 4168

A METHOD FOR CALCULATION OF HYDRODYNAMIC LIFT FOR SUBMERGED AND PLANING RECTANGULAR LIFTING SURFACES. Kenneth L. Wadlin and Kenneth W. Christopher. January 1958. 34p. diagrs. (NACA TN 4168)

A method is presented for the calculation of lift coefficients for rectangular lifting surfaces of aspect ratios from 0.125 to 10 operating at finite depths beneath the water surface, including the zero depth or planing condition. Theoretical values are compared with experimental values obtained at various depths of submergence with lifting surfaces of aspect ratios from 0.125 to 10. The method can also be applied to hydrofoils with dihedral. Lift coefficients computed by this method are in good agreement with existing experimental data for aspect ratios from 0.125 to 10 and dihedral angles up to 30°.

CURRENT NACA RESEARCH REPORTS

NACA TN 4172

NOISE SURVEY UNDER STATIC CONDITIONS OF A TURBINE-DRIVEN FULL-SCALE MODIFIED SUPERSONIC PROPELLER WITH AN ADVANCE RATIO OF 3.2. Max C. Kurbjun. January 1958. 17p. diagrs., photo., tabs. (NACA TN 4172)

Overall sound-pressure levels and frequency spectra of the noise emitted from a 10-foot-diameter, 1,700-rpm, three-blade modified supersonic propeller mounted on a turbine-powered airplane have been measured under static conditions around a circle with a 100-foot radius about the propeller hub. The results are compared with the results from a supersonic and a conventional subsonic propeller. The effects of power and rotational speed change on the noise levels and spectra are also shown.

NACA TN 4176

EFFECT OF FLOW INCIDENCE AND REYNOLDS NUMBER ON LOW-SPEED AERODYNAMIC CHARACTERISTICS OF SEVERAL NONCIRCULAR CYLINDERS WITH APPLICATIONS TO DIRECTIONAL STABILITY AND SPINNING. Edward C. Polhamus. January 1958. 54p. diagrs., photo., tab. (NACA TN 4176)

Cylinders with several cross-sectional shapes (including squares having various corner radii, rectangles, and a triangle) were studied. Since the flow incidences correspond to combined angles of attack and sideslip in the crossflow plane of three-dimensional bodies, the two-dimensional side-force results appear to have strong implications with regard to directional stability at high angles of attack and these implications, along with those associated with spin characteristics, are briefly discussed.

NACA TN 4177

WIND-TUNNEL INVESTIGATION OF THE STATIC LONGITUDINAL STABILITY AND TRIM CHARACTERISTICS OF A SWEPTBACK-WING JET-TRANSPORT MODEL EQUIPPED WITH AN EXTERNAL-FLOW JET-AUGMENTED FLAP. Joseph L. Johnson, Jr. January 1958. 89p. diagrs., tab. (NACA TN 4177)

The investigation included tests of the model to determine the effects of wing position, vertical position of the horizontal tail, and size of the horizontal tail for a range of momentum coefficients up to about 4. The model had a 30° sweptback wing with an aspect ratio of 6.60. Calculations were made to compare the relative merits of various trim devices for use on airplanes equipped with jet-augmented flaps.

NACA TN 4178

LOW-SPEED CASCADE INVESTIGATION OF COMPRESSOR BLADES HAVING LOADED LEADING EDGES. James C. Emery. January 1958. 76p. diagrs., photo., tabs. (NACA TN 4178. Supersedes RM L55J05)

Blade cambers having isolated-airfoil lift coefficients of 0.6, 1.2, 1.8, and 2.4 were tested over the usable angle-of-attack range for inlet-air angles of 30°, 45°, and 60° at solidities of 1.0 and 1.5. A comparative evaluation has been made of the results of this and previous cascade investigations of compressor blades having uniform chordwise loading as isolated airfoils and those having more loading at the trailing edge.

NACA TN 4179

ANALYTICAL INVESTIGATION OF ACCELERATION RESTRICTION IN A FIGHTER AIRPLANE WITH AN AUTOMATIC CONTROL SYSTEM. James T. Matthews, Jr. January 1958. 24p. diagrs. (NACA TN 4179)

A theoretical analysis was made to investigate the acceleration-restriction capabilities of several types of normal-acceleration control systems in a typical subsonic jet fighter airplane. The normal-acceleration response of the controlled airplane to simulated rough air was also investigated.

NACA TN 4182

PHYSICAL CHARACTERISTICS AND TEST CONDITIONS OF AN ETHYLENE-HEATED HIGH-TEMPERATURE JET. Roland D. English, Abraham Spinak, and Eldred H. Helton. January 1958. 28p. diagrs., photos. (NACA TN 4182)

A ground test facility has been developed at the Langley Pilotless Aircraft Research Station at Wallops Island, Va., that is capable of producing temperatures up to nearly 5,000° R. Conditions in the test section obtained from the calibration runs and from the calculated thermal properties of the exhaust gas are presented over the range of stagnation temperatures available.

NACA TN 4185

WIND-TUNNEL INVESTIGATION OF EFFECT OF SWEEP ON ROLLING DERIVATIVES AT ANGLES OF ATTACK UP TO 13° AND AT HIGH SUBSONIC MACH NUMBERS, INCLUDING A SEMIEMPIRICAL METHOD OF ESTIMATING THE ROLLING DERIVATIVES. James W. Wiggins. January 1958. 47p. diagrs., tab. (NACA TN 4185. Supersedes RM L54C26)

Results are presented of an investigation to determine the rolling derivatives for swept-wing—body configurations. The wing had sweep angles of 3.6°, 32.6°, 45°, and 60° at the quarter-chord line, an aspect ratio of 4, a taper ratio of 0.6, and an

NACA 65A006 airfoil section parallel to the free stream. Some tests were made of the 45° swept wing with fences located at the 65-percent-semispan station.

NACA TN 4189

LIFT AND MOMENT ON THIN ARROWHEAD WINGS WITH SUPERSONIC EDGES OSCILLATING IN SYMMETRIC FLAPPING AND ROLL AND APPLICATION TO THE FLUTTER OF AN ALL-MOVABLE CONTROL SURFACE. H. J. Cunningham. January 1958. 58p. diagrs. (NACA TN 4189)

A method based on linearized supersonic potential-flow theory, applied previously to vertical translation and pitching oscillations, is applied herein to symmetric flapping and rolling oscillations to obtain section and total unsteady lift and moment coefficients. Spanwise distributions are illustrated and compared with results of a strip-theory method. The aerodynamic coefficients are applied to a coupled-mode flutter analysis of an all-movable control surface for which the flexibilities are concentrated in a supporting shaft.

NACA TN 4190

EXPERIMENTAL INVESTIGATION OF THE LATERAL TRIM OF A WING-PROPELLER COMBINATION AT ANGLES OF ATTACK UP TO 90° WITH ALL PROPELLERS TURNING IN THE SAME DIRECTION. William A. Newsom, Jr. January 1958. 27p. diagrs. (NACA TN 4190)

The investigation was conducted with a model having four propellers, the slipstream from which covered practically the entire span of the wing. Tests were made at angles of attack up to 90° for various differential flap deflections and differential blade pitch on the outboard propellers. The lateral trim of the configuration tested was marginal. It seems likely, therefore, that some tilting-wing vertical-take-off airplanes could be trimmed with all the propellers rotating in the same direction whereas others could not.

NACA TN 4193

SUBSONIC FLIGHT INVESTIGATION OF METHODS TO IMPROVE THE DAMPING OF LATERAL OSCILLATIONS BY MEANS OF A VISCOUS DAMPER IN THE RUDDER SYSTEM IN CONJUNCTION WITH ADJUSTED HINGE-MOMENT PARAMETERS. Harold L. Crane, George J. Hurt, Jr., and John M. Elliott. January 1958. 45p. diagrs., photos., tab. (NACA TN 4193. Supersedes RM L54D09)

A single-degree-of-freedom analysis used as a guide to adjust the parameters is presented. A brief discussion of related problems which may result from the application of such a viscous damping device is given. The results of rudder trailing-edge strips to control rudder floating tendency are presented.

NACA TN 4195

SHAPE OF INITIAL PORTION OF BOUNDARY OF SUPERSONIC AXISYMMETRIC FREE JETS AT LARGE JET PRESSURE RATIOS. Eugene S. Love and Louise P. Lee. January 1958. 29p. diagrs. (NACA TN 4195)

Calculations have been made of the initial portion of the boundary of axisymmetric free jets exhausting at large pressure ratios from a conically divergent nozzle having a jet exit Mach number of 2.5 and a semidivergence angle of 15°. The results of the calculations indicate the size and shape of the jet to be expected at large pressure ratios, the effects of ratio of specific heats, and the large initial inclinations of the boundary that are likely to be encountered by hypersonic vehicles at high altitude.

NACA TN 4198

EFFECTS OF AIRPLANE FLEXIBILITY ON WING STRAINS IN ROUGH AIR AT 35,000 FEET AS DETERMINED BY A FLIGHT INVESTIGATION OF A LARGE SWEPT-WING AIRPLANE. Richard H. Rhyne. January 1958. 23p. diagrs., tab. (NACA TN 4198)

A flight investigation was made on a large sweptback-wing bomber airplane and the results are compared with data previously obtained at low altitude (5,000 feet). The effects of wing flexibility on the wing strains were, on the average, about 20 percent larger at the higher altitude.

NACA TN 4199

A FLIGHT INVESTIGATION OF THE EFFECTS OF VARIED LATERAL DAMPING ON THE EFFECTIVENESS OF A FIGHTER AIRPLANE AS A GUN PLATFORM. Helmut A. Kuehnel, Arnold R. Beckhardt, and Robert A. Champine. January 1958. 30p. diagrs., photo., tabs. (NACA TN 4199. Supersedes RM L53F08a)

Flight tests were conducted at three conditions of damping and two atmospheric turbulence levels with fixed-reticle, gyro computing, and telescopic gunsights. Results of simulated strafing runs indicate that the gun-line dispersion could be expected to be decreased about 7 percent by increased lateral damping and to be increased about 85 percent by decreased damping and about 40 percent by rough air of the type encountered. Use of the telescopic sight indicated a 20-percent decrease in gun-line dispersion.

NACA TN 4201

COLLECTION OF ZERO-LIFT DRAG DATA ON BODIES OF REVOLUTION FROM FREE-FLIGHT INVESTIGATIONS. William E. Stoney, Jr. January 1958. 373p. diagrs., tabs. (NACA TN 4201)

This report presents a compilation of most of the zero-lift drag results obtained from free-flight measurements made by the Langley Pilotless Aircraft Research Division on fin-stabilized bodies of revolution. The data are arranged on standard forms, which also contain the significant geometrical factors. Supplementary data have been provided to facilitate the determination of the body pressure drags from the measured total drags. Summary plots and discussions have been included to provide a unified and broad picture of the effects of body geometry on zero-lift drag.

NACA TN 4208

TURBULENT BOUNDARY LAYER ON A YAWED CONE IN A SUPERSONIC STREAM. Willis H. Braun. January 1958. 39p. diagrs. (NACA TN 4208)

The momentum integral equations are derived for the boundary layer on an arbitrary curved surface, using a streamline coordinate system. Computations of the turbulent boundary layer on a slightly yawed cone are made for a Prandtl number 0.70, wall to free-stream temperature ratios of 1/2, 1, and 2, and Mach numbers from 1 to 4. Deflection of the fluid in the boundary layer from outer stream direction, local friction coefficient, displacement surface, lift coefficient, and pitching-moment coefficient are presented.

THE REDUCTION TO STANDARD CONDITIONS OF TAKE-OFF MEASUREMENTS ON TURBO-JET AIRCRAFT. G. Jackson. APPENDIX II. K. J. Lush. 1957. 20p. tabs. ARC R & M 2890; ARC 14,127. Supersedes AAEE/Res/253. (Ask for N-10531X*)

A reduction method intended for routine use is derived whereby the take-off distance required for a turbojet aircraft to clear a 50-ft screen under a specified set of standard conditions of air temperature and pressure, wind speed, aircraft weight, and engine speed can be deduced from the distance measured in an arbitrary set of conditions. The method is basically similar to that used for piston-engined aircraft and the only information required in addition to that which can be observed is a numerical constant for the engine type. The method is shown to be not inconsistent with available experimental data.

N-14217X*

Aeronautical Research Council (Gt. Brit.)
AN APPROXIMATION TO THE SLOW MODE OF LONGITUDINALLY DISTURBED MOTION OF AN AIRCRAFT IN LEVEL FLIGHT. A. W. Thorpe. 1957. 27p. diagrs., tabs. ARC R & M 2907; ARC 14,759. Supersedes RAE Aero 2438. (Ask for N-14217X*)

This report develops an approximate theory of longitudinal response which applies to the slow mode of motion after a disturbance. This theory is complementary to that for the quick-period motion given by Gates and Lyon (1944). It predicts the slow motions which occur after the quick-period motions have died out. The approximate equations given are of second order only and can therefore be solved algebraically. This has been done and the general solutions are given in tables 1 and 2. Some numerical examples have been computed to indicate the accuracy which can be expected. The agreement with the first approximation is quite good and in some components it can be improved by the use of a further correction term.

AERODYNAMIC COEFFICIENTS FOR AN OSCILLATING DELTA WING. Doris E. Lehrian, National Physical Laboratory. 1957. 10p. diagrs., tabs. ARC R & M 2841. Supersedes ARC 14,156; 0.951. (Ask for N-14287X*)

Aerodynamic coefficients are calculated by the method described by Jones in R & M 2470 for a delta wing of AR = 3 which is assumed to be describing pitching and vertical translational oscillations of small amplitude in incompressible inviscid flow. The coefficients are calculated for values of 0.26 and 0.8 of the mean frequency parameter $\omega_m (\equiv pc_m/V)$, and certain of the coefficients are also obtained for $\omega_m \to 0$. It appears that the method provides a reasonable basis for calculating flutter derivatives, but it is not satisfactory for estimating all the stability derivatives. A modified version has been developed for the latter.

Aeronautical Research Council (Gt. Brit.)
A METHOD OF PERFORMANCE ESTIMATION FOR AXIAL-FLOW TURBINES. D. G. Ainley and G. C. R. Mathieson. 1957. 30p. illus. ARC R & M 2974; ARC 14,882. Supersedes NGTE R.111. (Ask for N-16026X*)

A method for calculation of the performance of conventional axial-flow turbines is presented. It makes use of data derived from the analysis of a large number of turbine tests and other associated test work reported elsewhere. The method enables the performance of a turbine to be calculated over a wide part of its full operating range. It is estimated that the tolerance on the absolute values of gas mass flow and peak efficiency will be in the region of ±2.0 percent for efficiency and ±3 percent for gas mass flow on present-day types of turbine. The method is illustrated by a worked example.

LOW-SPEED WIND-TUNNEL MEASUREMENTS OF LONGITUDINAL OSCILLATORY DERIVATIVES ON THREE WING PLAN-FORMS. G. F. Moss. 1957. 35p. diagrs., photos., tabs. ARC R & M 3009; ARC 15,972. Supersedes RAE Tech. Note Aero 2208. (Ask for N-23832X*)

Tests have been made on a 90° apex delta wing, a 60° sweptback wing, and a 40° sweptback wing to obtain values of longitudinal oscillatory derivatives for various frequencies, amplitudes, and Reynolds numbers. Values of $m_{\dot{\theta}}$ were obtained for all three and z_w for the delta model using free oscillation methods. In addition, z_θ, $z_{\dot{\theta}}$, m_θ, and $m_{\dot{\theta}}$ were measured by a forced oscillation method for the delta wing and the 60° sweptback wing. The effects of reduced frequency (over the range 0.01 to 0.3) amplitude (±1/2° to ±2° in pitch) and Reynolds number (0.72×10^6 to 3.3×10^6) were found to be small.

Aeronautical Research Council (Gt. Brit.)
THE DESIGN AND TESTING OF AN AXIAL COMPRESSOR HAVING A MEAN STAGE TEMPERATURE RISE OF 30 DEG C. A. D. S. Carter, S. J. Andrews, and E. A. Fielder. 1957. 14p. diagrs. ARC R & M 2985; ARC 16,775. Supersedes NGTE R. 148. (Ask for N-30303X*)

This report describes a compressor which was designed to give a mean stage temperature rise of 30° C. It has six stages so that the overall pressure ratio at the design point is 4·5:1. Full details of the factors which led to the form adopted and of the design itself are given in the report. The test results fully substantiated the design assumptions. In particular, using standard design data, it is possible to achieve temperature rises of about 30° C without sacrificing unduly any desirable performance features. Such temperature rises were considerably above those being used at the time this work was carried out, and are in fact substantially above the mean value used in present-day designs. Details of the stage characteristics and the matching of the compressor have been given in the report, together with some other points of special interest.

Aeronautical Research Council (Gt. Brit.)
FLIGHT TESTS ON A VAMPIRE Mk. 5 WITH A REDESIGNED ANTI-SNAKING RUDDER. W. J. G. Pinsker. 1957. 16p. diagrs., tab. ARC R & M 3014; ARC 16,815. Supersedes RAE Aero 2506. (Ask for N-30501X*)

A specially designed rudder has been fitted to a Vampire Mk. 5 to act as an aerodynamic yaw damper. Flight tests show that the damping of the lateral oscillation has been substantially increased, in consequence, a logarithmic decrement greater than unity being attained even at 40,000-ft altitude. This is a considerable improvement on the results obtained previously on the same aircraft, when the standard rudder was used as the damping surface. Air-to-air aiming is shown to have benefited from the effect of the damping rudder.

Aeronautical Research Council (Gt. Brit.)
THEORY OF AEROFOILS ON WHICH OCCUR BUBBLES OF STATIONARY AIR. L. C. Woods. 1957. 16p. diagrs. ARC R & M 3049. Supersedes ARC 16,277; S & C 2825; FM 1973. (Ask for N-32208X*)

Spoilers, split flaps, and sometimes (with thin airfoils) incidence alone cause the flow to separate from the airfoil surface. This flow often reattaches to form a closed bubble of virtually stationary air at a fairly constant pressure. The paper sets out a mathematical theory of the subsonic inviscid flow external to the bubble whose position is assumed. The influence of the bubble on the lift and moment coefficients is calculated and some comments are made about the stalling of thin airfoils.

N-32876X*

Aeronautical Research Council (Gt. Brit.)
AN ANALYSIS OF THE LONGITUDINAL STABILITY AND CONTROL OF A SINGLE-ROTOR HELICOPTER. F. O'Hara. 1957. 22p. diagrs. ARC R & M 2958; ARC 16,954. Supersedes AAEE/Res/280. (Ask for N-32876X*)

The general theory of longitudinal stability and control for a single-rotor helicopter is presented in a form similar to that for fixed-wing aircraft. It is shown to be possible to establish for the helicopter in forward flight, in the same way as for fixed-wing aircraft, stick-fixed static and maneuver margins, on which the stability and handling qualities depend to a marked extent. Theoretical relations are derived for static margin, K_n, and maneuver margin, H_m, in a general form covering the case of a tail plane linked to the rotor control. Relations are also given for determining K_n and H_m from measured control changes to trim.

WIND-TUNNEL WALL INTERFERENCE EFFECTS ON OSCILLATING AEROFOILS IN SUBSONIC FLOW. W. P. Jones. 1957. 21p. diagrs., tabs. ARC R & M 2943. Supersedes ARC 16,430; 0.1091; FM 2005; S & C 2846. (Ask for N-34058X*)

A theory is developed for estimating the effect of wind-tunnel walls on the air forces acting on an airfoil oscillating in a subsonic airstream. It can only be applied for a range of frequencies well below the frequency at which transverse vibrations of the airstream may be induced. The possibility of resonance occurring for certain combinations of tunnel height, frequency of oscillation of airfoil, wind speed, and Mach number was first pointed out by Runyan and Watkins, and the present paper confirms their conclusions. The method is applied to calculate aerodynamic derivatives for an oscillating flat plate in a wind tunnel of height equal to 4.75 airfoil chord and M = 0.7.

SCALE EFFECTS AT HIGH SUBSONIC AND TRANSONIC SPEEDS, AND METHODS FOR FIXING BOUNDARY-LAYER TRANSITION IN MODEL EXPERIMENTS. A. B. Haines, Royal Aircraft Establishment; D. W. Holder and H. H. Pearcey, National Physical Laboratory. 1957. 37p. diagrs., photos. ARC R & M 3012; ARC 17,225. Supersedes RAE Tech. Note Aero 2338. (Ask for N-34306X*)

Several methods which can be used to fix transition are described, and the results obtained by using them are compared. In general, in experiments in two-dimensional flow, good agreement is found, and explanations can be advanced for cases in which discrepancies occur. Several uncertainties and difficulties that arise in fixing transition are discussed and illustrated by examples; three-dimensional tests are also discussed.

THE STRENGTH OF ANNEALED AND HEAT-TREATED GLASS. F. G. J. Brown and J. Ellis. 1957. 37p. diagrs., tabs. ARC R & M 3003; ARC 17,253. Supersedes RAE Structures 167. (Ask for N-34390X*)

This report develops statistical methods of choosing allowable design stresses for annealed and heat-treated glass. The results are easy to apply but additional fundamental knowledge of some properties of glass is needed before they can be used to the best advantage. The report draws attention to these gaps in existing knowledge and makes recommendations for further research. The report discusses the influence of the known causes of strength variations between nominally identical specimens in relation to two types of glass typical of those used by the aircraft industry, and shows that improved control of heat-treatment processes offers the best hope of a big increase in the useful strength of glass.

A SURVEY OF THE ALTERNATING PRESSURES EXCITING HIGH FREQUENCY VIBRATIONS IN GAS TURBINES. J. R. Forshaw. 1957. 20p. diagrs., photo., tabs. ARC R & M 2989; ARC 17,133. Supersedes NGTE R. 158. (Ask for N-34618X*)

A survey of the predominant harmonic components of the alternating pressures is made for three centrifugal compressors, three axial-flow compressors, and a single-stage turbine to ascertain the forces exciting vibration in a compressor or turbine stage. The amplitude of the alternating pressures is dependent on the work done in a blade or impeller vane passage, the incidence at entry to the stage, the exit conditions, and the general flow conditions and there is usually a relative reduction when operating near the design point. There is a reduction in the alternating pressures with distance from the source, particularly across a blade row. Three other sources of excitation at part load are also discussed.

THE FORMATION OF REGIONS OF SEPARATED FLOW ON WING SURFACES. PART II - LAMINAR SEPARATION BUBBLES AND THE MECHANISM OF THE LEADING-EDGE STALL. L. F. Crabtree. July 1957. 22p. diagrs., tab. RAE Aero 2578. (Ask for N-34952, pt. 2*)

The characteristics of laminar separation bubbles on thin and moderately thin airfoil sections at low speeds are discussed and explained. Further experimental confirmation of Owen's criterion for distinguishing between long and short bubbles is presented. Results of this investigation also show that there is no universal value of the boundary-layer Reynolds number at separation, $(R_{\delta 1})_s$, at which short bubbles break down into long bubbles. Some of the main gaps in previously published pictures of laminar separation bubbles are filled in so that a reasonably complete and coherent explanation of the characteristics of such flows is now possible. At the same time, this picture of bubble flows enables a more satisfactory explanation to be given of the scale effect on maximum lift and stalling characteristics of those airfoils which experience such bubble separations.

Aeronautical Research Council (Gt. Brit.)
MEASUREMENTS OF THE EFFECT OF WINDSCREEN SHAPES ON THE DRAG OF COCKPIT CANOPIES AT TRANSONIC AND LOW SUPERSONIC SPEEDS USING THE FREE-FLIGHT–MODEL TECHNIQUE. C. Kell. 1957. 10p. diagrs., photos., tabs. ARC R & M 3024; ARC 17,611. Supersedes RAE Aero 2529. (Ask for N-36532X*)

The effect of changes in the shape of the windscreen on the drag of a cockpit canopy has been measured on models in free flight. Canopies were attached to the models by means of a flexible mounting in such a way as to allow the canopy drag to be measured directly. The drag of the canopy was measured over a range of Mach numbers between 0.85 and 1.55 and the results show the improvements to be obtained by variations in the sweep of a vee windscreen and changes in the angle of a sloping windscreen.

ON AERODYNAMIC SURFACE SOUND. O. M. Phillips, Trinity College. March 28, 1955 (revised). 14p. ARC 16,963; FM 2099. (Ask for N-36622*)

When a fluid in irregular or turbulent motion moves across the surface of a rigid body, dipole sound radiation can be produced by the fluctuating stress distribution set up at the boundary. This radiation generated by the interaction of fluid in motion with rigid surfaces is called aerodynamic surface sound. It is the purpose of this paper to establish some of the fundamental properties of the generation of sound in this manner. An integral theorem is derived which relates the motion over the surface and which can be applied in several cases to derive properties of the surface radiation field in a given flow.

THE AERODYNAMIC EFFECTS OF ASPECT RATIO AND SWEEPBACK ON WING FLUTTER. W. G. Molyneux and H. Hall. 1957. 17p. diagrs., tabs. ARC R & M 3011; ARC 17,782. Supersedes RAE Structures 175. (Ask for N-36845X*)

The report describes tests to obtain direct measurements of the aerodynamic effects of aspect ratio and sweepback on wing flutter. The tests were made on rigid wings with root flexibilities. It is shown that measured effects of aspect ratio and sweepback on the flutter of these wings can be represented quite closely in flutter calculations based on two-dimensional-flow theory by multiplying the two-dimensional aerodynamic coefficients by appropriate factors. The effect of sweepback is represented by multiplying all aerodynamic coefficients by $\cos \Lambda$, where Λ is the wing leading-edge sweepback, and the effect of aspect ratio is represented by multiplying the aerodynamic damping coefficients by $1/f(A)$ and the stiffness coefficients by $1/[f(A)]^2$ where A is the aspect ratio. For the wings tested an average value for $f(A)$ is $f(A) = \{1 + (0.8/A)\}$.

Aeronautical Research Council (Gt. Brit.)
DERIVATIVE MEASUREMENTS AND FLUTTER TESTS ON A RECTANGULAR WING WITH A FULL-SPAN CONTROL SURFACE, OSCILLATING IN MODES OF WING ROLL AND AILERON ROTATION. W. G. Molyneux and F. Ruddlesden. 1957. 26p. diagrs., photos., tabs. ARC R & M 3010; ARC 17,751. Supersedes RAE Structures 172. (Ask for N-36895X*)

Details are given of tests to measure the aerodynamic coefficients for a rectangular wing with a full-span aileron oscillating in modes of wing roll and aileron rotation. A new technique was used in which aileron rotation was geared to wing roll so that oscillation occurred in both degrees of freedom simultaneously. The measured coefficients are compared with those derived from two-dimensional theory, and with coefficients estimated by an empirical method. The agreement with theory is poor but the estimated coefficients agree well with those measured. Flutter calculations for the system were made using both measured and theoretical derivatives, and the results are compared with flutter test results. The calculated flutter speed using measured derivatives agrees closely with that measured, whereas using theoretical derivatives the agreement is poor.

Aeronautical Research Council (Gt. Brit.)
THE INFLUENCE OF DESIGN PRESSURE RATIO AND DIVERGENCE ANGLE OF THE THRUST OF CONVERGENT-DIVERGENT PROPELLING NOZZLES. P. F. Ashwood and D. G. Higgins. 1957. 31p. diagrs., tabs. ARC CP 325. (Ask for N-38243X*)

Tests were made of two groups of Laval type convergent-divergent propelling nozzles over a range of pressure ratios up to 9:1 using air at sensibly ambient temperature. The nozzles of the first group were designed for pressure ratios of 4, 6, 8, 10, and 12 and had an included divergence angle of 20° while those of the second group were all designed for a pressure ratio of 8 and had included divergence angles of 5°, 10°, 20°, 30°, and 50°. The superior thrust performance at high-pressure ratios of the Laval type nozzles over that of a plain convergent nozzle has been demonstrated. The effect of divergence angle on the thrust has been examined and, within the range 5° to 25°, found to be small. A comparison between the Busemann type profiled nozzle and an equivalent nozzle having a straight conical divergence has shown that at the design point the profiled nozzle gives about 2 percent more thrust.

THE EFFECTS OF TAPER ON THE SUPERVELOCITIES ON THREE-DIMENSIONAL WINGS AT ZERO INCIDENCE. K. W. Newby. 1957. 75p. diagrs., tab. ARC R & M 3032; ARC 18,205. Supersedes RAE Aero 2544. (Ask for N-40188X*)

Relationships have been derived for expressing the velocities on three-dimensional tapered wings at zero incidence in terms of the velocities on untapered infinite swept wings. The theoretical investigation of the effects of taper is confined to simple wings having airfoil sections formed by cubic or parabolic arcs; some experimental evidence is given to show that the results of this investigation can probably be applied quantitatively to wings having conventional airfoil sections. The results given in this report show that plan form and thickness taper have a marked effect on the velocities near the center of a wing, but that these effects decrease with increase of sweepback. A calculation method is outlined in the text for applying the results obtained for wings having parabolic-arc airfoil sections, to wings having arbitrary section shapes.

AN EXPERIMENTAL INTRODUCTION TO THE JET FLAP. N. A. Dimmock. 1957. 68p. diagrs., photos., tabs. ARC CP 344. (Ask for N-44558X*)

This paper records the experimental results obtained with two two-dimensional airfoils, each having a 12.5-percent-thick elliptical cross section with a narrow full-span jet slot at the trailing edge, the jet deflections being respectively 90° and 31.4°. It is shown that the values of the force and moment coefficients and derivatives obtained experimentally agree satisfactorily with those suggested by the theory of reference 2. Support is given to the thrust hypothesis in that the measured thrust was greater, under appropriate conditions, than the reaction component from the deflected jet. The losses in the system have been considered and some of them investigated, those due to Reynolds number and jet entrainment effects being included. Also, the influence of ground proximity on the lift and center of lift of the 31.4° model was measured at zero incidence and found not to be prohibitive. A tentative empirical expression is suggested for the pitching-moment coefficient.

Aeronautical Research Council (Gt. Brit.)
EXPERIMENTAL INVESTIGATION OF THE PRESSURE DISTRIBUTION AT THE CENTRE-SECTION OF A SWEPTBACK WING AT HIGH SUBSONIC SPEEDS. T. E. B. Bateman and A. J. Lawrence. 1957. 35p. diagrs., photos., tabs. ARC CP 367. (Ask for N-46416X*)

Measurements have been made on a 40° sweptback wing over the Mach number range of 0.50 - 0.94, at zero incidence. Given pressures are reached further aft at the center section than on a section of the infinite sheared wing. In particular, the supersonic region, when formed, occurs much further aft and the shock wave moves quickly to a position close behind the trailing edge. The isobars lose their sweep in the neighborhood of the center section and this reduces the critical Mach number from 0.38 for the sheared wing to 0.81 for the center section. The maximum local Mach number at the center section tends to a steady value of about 1.15 at high subsonic speeds. Theoretical estimates of the pressure distributions on the sheared wing at zero incidence are shown to agree well with the measured values for speeds at which no shock waves form but estimates for the center section agree well only at very low speeds.

DEVELOPMENT OF THE R.A.E. 6 INCH DIAMETER SHOCK TUBE. PART 1. BURSTING OF DIAPHRAGMS AT 200 ATMOSPHERES. S. G. Cox. May 1957. 12p. diagrs., photo. RAE Tech. Note Aero 2510. (Ask for N-50050, pt. 1*)

The problem of providing a diaphragm section for the R.A.E. high-temperature shock tube has been investigated experimentally with a test rig. From these tests it has been found that cold rolled S.3 steel, as received, is a satisfactory material for the diaphragm of a 6-inch-diameter tube at chamber pressures up to 200 atmospheres. With this material, scored lines across the diameters of the diaphragms gave no improvement. It is inadvisable to use diaphragms of less than 16 standard wire gage thickness if consistent results are to be obtained, since thin diaphragms tend to be torn away and petalling is very ragged. The final method of clamping the diaphragm with a free piston and sealing with "O" rings has proved very successful and diaphragms of different thicknesses can be inserted quickly and easily.

Royal Aircraft Establishment (Gt. Brit.)
A NOTE ON COMBUSTION DRIVEN SHOCK TUBES. G. A. Bird. May 1957. 18p. diagrs. RAE Tech. Note Aero 2511. (Ask for N-50051*)

The method of characteristics has been used to make a detailed study of the flow in a shock tube in which the high-pressure gas has been raised to a high temperature and pressure by combustion. A number of examples were considered in which the diaphragm is broken by the combustion process, which may be either a fast or slow combustion wave or a detonation wave. In all these cases it was found that the resultant shock could have a higher speed than that produced by constant volume combustion but its velocity changed as it traveled down the tube and the flow between it and the contact surface was not uniform even with friction and conduction effects neglected. It was concluded that, if it is desired to use the flow behind the shock as a short duration wind tunnel, constant volume combustion should be used.

NOTE ON THE CIRCULATION IN CIRCUITS WHICH CUT THE STREAMLINES IN THE WAKE OF AN AEROFOIL AT RIGHT-ANGLES. J. H. Preston, Cambridge U. 1956. 8p. diagrs. ARC R & M 2957. Supersedes ARC 16,622; FM 2043. (Ask for N-50082X*)

It has been suggested that, in the two-dimensional flow of a real fluid, the circulations in all circuits enclosing the airfoil and cutting the streamlines in the wake at right angles would be very nearly the same. This is of fundamental importance in the calculations of the lift of airfoils allowing for the boundary layer. Recent developments in connection with the effect of a jet issuing from the trailing-edge region on the lift of an airfoil have raised the question of a satisfactory explanation of this effect and its prediction. Elementary considerations, which are set out below, suggest that, in the case of an airfoil with jet, the above is not true. It would also appear that it is not quite true with an airfoil with wake, since the same arguments can be applied. In the case of the airfoil with a strong jet, the existence of circulation in circuits not enclosing the airfoil but cutting the jet twice at right angles is of decisive importance in explaining the jet effects.

A STUDY OF THE AIRCRAFT ARRESTING-HOOK BOUNCE PROBLEM. J. Thomlinson. 1957. 46p. diagrs. ARC R & M 2980; ARC 16,985. Supersedes RAE Tech. Note NA 263. (Ask for CN-50108X*)

The kinematics of an arresting-hook unit are studied in order to determine, within the limits of the assumption of a perfectly rigid hook unit, the damper force necessary to control hook bounce. The necessity for a smooth deck and the desirability of small trail angle for the hook unit are demonstrated from several aspects. The design requirements for a hook damper unit are discussed in all their functional aspects and methods are given for determining the up-swing motion of an arresting hook unit immediately following engagement of an arresting wire. The behavior of arresting wires after being depressed by the passage of aircraft wheels is also outlined.

THE INFLUENCE OF DRAG CHARACTERISTICS ON THE CHOICE OF LANDING APPROACH SPEEDS. D. Lean and R. Eaton. (Paper for presentation to the AGARD Flight Test Panel, London, May 1957.) April 1957. 25p. diagrs., tabs. RAE Tech. Note Aero 2503. (Ask for N-54139*)

A study has been made of the lift-drag characteristics of 19 jet aircraft which have minimum comfortable approach airspeeds that are fairly well established. On about half these aircraft, drag effects, which determine speed stability, were stated to limit the approach airspeeds, though there was naturally some lack of unanimity as to the level of the effect which could be classed as tolerable. Limiting values of speed stability are proposed for the three types of landing approach used for carrier, airfield, and instrument landings. The speeds corresponding to these stability levels are in fair agreement with those actually used, even for those aircraft whose approach speeds were not primarily limited by drag effects. It is considered that drag effects must be taken into account in estimating approach airspeeds, and that this process materially improves the prediction of approach speeds for the latest types of aircraft. Further data should be collected and analyzed in order to confirm or modify the form or level of the proposed limits.

ON THE NON-LINEAR THEORY OF HYDRODYNAMIC STABILITY. J. T. Stuart, National Physical Laboratory. August 28, 1957. 28p. diagrs. ARC 19,493; FM 2577. (Ask for N-54308X*)

In this paper, the effects of Reynolds stresses on the growth of small disturbances in an unstable basic flow are discussed. It is shown by means of energy considerations that often a finite disturbance of definite amplitude is possible, associated with a distorted mean flow. The cases treated include Poiseuille flow between parallel planes, flow between rotating cylinders, and thermal instability. For the case of flow between rotating cylinders, good agreement is obtained with G. I. Taylor's measurements of the torque required to maintain the cylinders in motion against the retardation due to the fluid.

AN EXPERIMENTAL VERIFICATION OF THE THEORETICAL CONCLUSIONS OF R. A. E. TECHNICAL NOTE NO. STRUCTURES 156 (A. R. C., C. P. NO. 286). "A CONSTRUCTIONAL METHOD FOR MINIMISING THE HAZARD OF CATASTROPHIC FAILURE IN A PRESSURE CABIN" WITH FURTHER COMMENTS ON ITS IMPLICATIONS. D. Williams. 1957. 13p. diagrs. ARC CP 357.
(Ask for CN-57210X*)

In a recent paper the author described a method of construction intended to make the shell of a pressure cabin immune from catastrophic failure at little or no cost in extra weight. The present note records the results of experiments carried out on a Comet I cabin that was modified to incorporate the new constructional method. These experiments, which include some very searching tests, amply confirm the benefits indicated by theory, and appear fully to vindicate the new method of construction. The note also touches on the momentous implications that arise once this type of construction is accepted as meeting the claims made for it.

THE DEVELOPMENT OF A VARIABLE MACH NUMBER EFFUSER. J. B. McGarry. August 1957. 26p. diagrs., photo. NGTE R. 210.
(Ask for N-57219*)

A series of tests was undertaken on a simple, two-dimensional, variable Mach number effuser, or nozzle, designed for the range of supersonic flows up to Mach number 3.0. The performance of the nozzle was assessed from the magnitude of the percentage variation in its exit Mach number distribution. Studies of the effect on the performance of alterations to the position of the nozzle block pivots and other geometrical features were made. On the basis of these studies, a final build of nozzle was developed which produced flow of a uniformity sufficient for intake and engine model testing over the Mach number range from 1.5 to 3.0.

SOME OBSERVATIONS ON THE AIR AND CORROSION FATIGUE BEHAVIOR OF A TERNARY ALUMINIUM-ZINC-MAGNESIUM ALLOY. INTERIM REPORT. C. A. Stubbington and P. J. E. Forsyth. March 1957. 27p. diagrs., photos., tabs. RAE Tech. Note Met. 258. (Ask for N-57271*)

The present work was carried out to obtain fundamental information on the causes of the low fatigue properties of the high strength aluminum alloys under air and corrosion fatigue conditions. In order to avoid the unnecessary complications of intermetallic particles a simple aluminum alloy containing 7.5 percent zinc, 2.5 percent magnesium, was chosen for the investigation. Earlier work on D. T. D. 683 indicated that heat treatment might influence the subsequent fatigue behavior of this material, and therefore one of the purposes of the investigation was to compare the fatigue behavior of the simple ternary alloy after various carefully controlled and reproducible heat treatments. The work reported in this note is mainly of a metallographic nature, but some quantitative results are also included.

SHEAR FLOW THROUGH A CASCADE. W. R. Hawthorne and W. D. Armstrong, Cambridge University. February 21, 1955. 33p. diagrs. ARC 17,390; EA 390; FM 2190. (Ask for N-57278*)

This is a theoretical and experimental study of the flow through a cascade of untwisted airfoils placed in a wind tunnel of rectangular cross section in which the approach velocity was varied artificially in the spanwise direction only. Local pressure differences produce rotational secondary flows which cause overall spanwise accelerations and displacements. These effects are analyzed for frictionless flow by treating the blade row as an actuator plane whose outlet angle is determined by the secondary velocities in the blade passages.

THE MATRIX FORCE METHOD OF STRUCTURAL ANALYSIS AND SOME NEW APPLICATIONS. J. H. Argyris and S. Kelsey, University of London. 1957. 42p. diagrs., tabs. ARC R & M 3034; ARC 18,234. (Ask for N-57282*)

The purpose of this paper is: (a) To summarize the basic principles of the matrix force method of structural analysis and to present also some new applications of the general theory. (b) To establish and illustrate on simple examples the special method of cutouts. In this procedure the stresses in a structure with cutouts are derived from the simpler analysis of the corresponding structure without cutouts under the same loads and/or temperature distribution. (c) To present a method for the determination of the stresses in a structure, some of whose components have been modified subsequent to an initial stress analysis. This procedure is a generalization of the cutout method (b) and gives the stresses in the modified system solely in terms of the stresses of the original system subject to the same loads and temperature distribution.

THE SECONDARY FLOW IN A CASCADE OF TURBINE BLADES. W. D. Armstrong, University of Cambridge. 1957. 14p. diagrs., photo.
ARC R & M 2979; ARC 17,442. (Ask for N-57283*)

It is shown that when the secondary vorticity is sufficiently small perturbation theory may be used to predict accurately the induced velocities downstream of the blades which are due to this distributed vorticity. As the upstream vorticity or the blade deflection is increased then the perturbation theory is no longer applicable and the transport of the Bernoulli surfaces within the blade passages must be considered. In a particular case a crude approximate method has been given for the calculation of the distributed circulation but this itself does not enable the induced velocities to be computed. Experimental eivdence is presented to show that downstream of the cascade there are, for each blade, two adjacent regions of low total head which rotate in opposite directions. One of these regions originates from the blade shed circulation and the other from the distributed secondary circulation within the blade passage.

SOME ASPECTS OF THE CATALYTIC DECOMPOSITION OF HYDROGEN PEROXIDE BY SILVER. PART VI. SOLUTIONS SATURATED WITH SILVER. D. Sutton. May 1957. 9p. diagrs. RAE Tech. Note RPD 135. (Ask for N-57287, pt. 6*)

The enhanced rate of decomposition which follows when a solution of hydrogen peroxide is saturated with silver is shown to be due to the large increase in catalytic surface brought about by the continuous precipitation of particles of silver in the decomposing solution. The changes in electrical conductivity and pH of such solutions have been measured during the course of decomposition. The results show that Ag^+ and HO_2^- ions are removed from solution as the peroxide concentration falls, the amounts remaining in solution being just sufficient to satisfy a limiting ionic product $[Ag^+][HO_2^-]$, which decreases progressively with the fall in peroxide concentration. The measured pH values are in good agreement with those calculated using the values of the ionic product $[H^+][HO_2^-]$ for hydrogen peroxide solutions determined by Wynne-Jones.

THE SHAPE OF THE CENTRE PART OF A SWEPTBACK WING WITH A REQUIRED LOAD DISTRIBUTION. J. Weber. May 1957. 51p. diagrs. RAE Aero 2591. (Ask for N-57288*)

A method is developed for designing the center portion of a cambered and twisted sweptback wing to have the same chordwise load distribution at all spanwise stations. For this purpose the downwash field induced by a doublet distribution of constant spanwise strength in the chordal plane of a constant chord wing is determined for incompressible, sonic, and supersonic mainstream flow. Since the downwash has a logarithmic singularity at the center section in the chordal plane itself, an approximate method is suggested to satisfy the boundary condition at the surface of the thick wing. Numerical examples illustrate the influence of the angle of sweep, the wing thickness, and the load distribution. They show in particular that the required shape does not vary much with Mach number. A relatively rapid change of twist and camber with the spanwise distance from the center section is required as shown by calculated results for sonic flow. There is some reason for using the camber and twist designed for the center section of the isolated wing also for wing-fuselage junctions.

CONTROL RESPONSE MEASUREMENTS ON A SINGLE-ROTOR HELICOPTER (WESTLAND "DRAGONFLY"). A. R. S. Bramwell. July 1957. 30p. diagrs., photos. RAE Tech. Note Naval 19. (Ask for CN-57289*)

Flight tests have been made to measure the longitudinal response of a single-rotor helicopter (Westland "Dragonfly") to sudden movements of the cyclic and collective pitch controls. The measured response to the cyclic pitch control agrees quite well with theoretical calculations. It is shown also that the response fails to satisfy the NACA maneuverability criterion, except perhaps at low speeds. It was found possible to obtain the rotor force derivative z_w from the response to cyclic and collective pitch displacements. The values so obtained show fair agreement with theory. Measurements of speed, attitude, and acceleration were made in control-initiated phugoid oscillations and a method is given for using them in conjunction with trim measurements to obtain all the longitudinal stability derivatives.

EXPERIMENTAL OBSERVATION OF VORTICES IN WING-BODY JUNCTIONS. A. Stanbrook. March 1957. 33p. diagrs., photos. RAE Aero 2589. (Ask for N-57292*)

Tests have been made on various wing-body combinations to investigate the nature of the flow in the junction. It was found that vortices are formed due to separation of the boundary layer on the body in the flow toward the wing. The free edge of the resulting vortex sheet rolls up to form the vortex which then trails downstream around the wing. As incidence is increased the vortex on the suction side of the wing moves toward the wing and the vortex on the pressure side moves away from the wing. The vortices are present with both swept and unswept rounded leading edges at subsonic and supersonic speeds but were not found with sharp leading edges at zero incidence.

FREE VIBRATIONS OF A STIFFENED CYLINDRICAL SHELL. P. R. Miller, University of Southampton. May 1957. 39p. diagrs. ARC 19,338; LA 22. (Ask for N-57360*)

This report presents the first stage of an investigation of the response to random noise of a stiffened cylinder, representing an aircraft fuselage, including an analysis of the lower modes of such a cylinder. The energy approach is then extended to give the resonant frequencies and natural modes of a circular cylindrical shell uniformly stiffened with closely spaced longerons and frames, "close spaced" implying that stiffener spacing is much less than the spacing of nodal lines. The effects of rotary inertia have had to be included owing to the lack of symmetry of the section about the skin, but shear deflections are still neglected. Further numerical work is required before much comment can be made on the results, but they seem to be similar in nature to those obtained for the uniform cylinder.

LOADING ON AN OSCILLATING WING OF INFINITE ASPECT RATIO IN A SUBSONIC STREAM. J. H. Wilkinson. June 17, 1957. 14p. ARC 19,344; Comp. 125. (Ask for N-57361*)

Direct methods of solution of the problem in its original form by orthodox relaxation techniques are not used in practice and this is probably due partly to difficulties arising in the field of numerical analysis and partly to the large volume of computation involved. With the advent of high-speed digital computers it was felt that the possibility of such a direct attack should be reconsidered. The present note describes work that has been done on this problem. It was early apparent that the difficulties involved were very substantial and accordingly the simplest problem, the linearized theory of a vibrating wing of infinite aspect ratio was attempted first.

SOME NOTES ON SHOCK-WAVE BOUNDARY-LAYER INTERACTIONS, AND ON THE EFFECT OF SUCTION ON THE SEPARATION ON LAMINAR BOUNDARY LAYERS. K. N. C. Bray. 1957. 11p. diagrs. ARC CP 332. (Ask for N-57362*)

A brief review is given of a theory, due to Crocco and Lees, which can be used for a wide range of laminar and turbulent boundary-layer problems. The results of applying this theory to the problem of shock wave boundary-layer interactions are described from a reference report. The same method is then applied to the problem of estimating the extent to which critical Mach number effects on a wing can be delayed by boundary-layer suction. In this report, a number of crude approximations have been made to find the order of magnitude of this effect. It is found that a sucked boundary layer may require almost three times as big a disturbance as an unsucked layer, in order to cause separation. As this preliminary result is quite encouraging, some suggestions are made for more accurate calculations.

INSTABILITY IN A SLOTTED WALL TUNNEL. J. L. King, P. Boyle, and J. B. Ogle. 1957. 24p. diagrs., tabs. ARC CP 343. (Ask for N-57363*)

Large pressure fluctuations have been observed in the working section of the Admiralty Research Laboratory's new 30-in. water tunnel. The present report describes investigations carried out in a 7-in. wind tunnel to examine such fluctuations in detail and also theoretical investigations which explain and describe the phenomena. It is shown theoretically that a jet of fluid circular in cross section moving through the same fluid is unstable. The slotted wall is unable to stabilize all frequencies of disturbance. The length of the working section determines preferred wavelengths of disturbance which feed energy back to the upstream end of the jet by compressing the fluid in the reservoir surrounding the working section. In the absence of a reservoir, the instability disappears. The present report is not concerned with the performance of the 30-in. tunnel or with measures now being taken to improve it.

DIRECT STRESS FATIGUE TESTS ON REDUX-BONDED AND RIVETED DOUBLE STRAP JOINTS IN 10 S.W.G. ALUMINIUM ALLOY SHEET. S. Kelsey and J. B. Spooner, Imperial College. 1957. 46p. diagrs., tabs. ARC CP 353. (Ask for N-57364*)

Tensile fatigue tests were carried out on sheet specimens in D.T.D. 610B, 546B, and 687A with double strap Redux and riveted joints. Bonded joints tended to fail by shear of the bond at the higher stress ranges and by tension of the sheet at the lower stress ranges. Riveted joints failed by tension across the first row of rivets in all cases, though tests on three-row riveted joints showed considerable improvement in endurance over those with two rows of rivets. Endurances were greater for bonded joints but with rather more scatter than for riveted joints, particularly where bond shear was the cause of failure.

EXPERIMENTS ON PITOT-TUBES IN SHEAR FLOW. F. A. MacMillan. 1957. 12p. diagrs. ARC R & M 3028; ARC 18,235. (Ask for N-57365*)

When a pitot tube is used in a pipe or boundary layer, the shear and the presence of the wall may cause the pressure in the tube to differ from the true total pressure on the axis of the tube. To investigate these effects measurements were made in a pipe of circular section, with turbulent flow, using pitot tubes of different external diameter. Some supporting experiments were also made in a turbulent boundary layer on a flat plate with zero pressure gradient.

AN INVESTIGATION OF THE VELOCITY DISTRIBUTION AROUND THE NOSE OF THE AEROFOIL WITH A FLAP. Ian H. Rettie. 1957. 15p. diagrs. ARC R & M 3027; ARC 17,633. (Ask for N-57366*)

The velocity distribution around the nose of an NACA 0015-64 airfoil was found by experiment and that around the nose of a Piercy 15/40 airfoil by calculation for various angles of incidence and flap deflection. It was established that at all incidences this velocity distribution is a function of the position of the stagnation point, irrespective of the flap deflection. This result is shown to be true generally, and it is suggested that use might be made of it in the design of a lift-coefficient meter, which could also be used to give warning of a stall.

CALCULATION OF THE FLOW PAST SLENDER DELTA WINGS WITH LEADING EDGE SEPARATION. K. W. Mangler and J. H. B. Smith. May 1957. 49p. diagrs., tabs. RAE Aero 2593. (Ask for N-57398*)

The flow past a slender delta wing with a sharp leading edge, at incidence, usually separates along this edge, that is, a vortex layer extends from the edge and rolls up to form a "core" (a region of high vorticity). A potential flow model of this is constructed in which the layer is replaced by a vortex sheet which is rolled up into a spiral in the region of the "core." This problem is reduced to a two-dimensional one by assuming a conical field and using slender wing theory. The shape and strength of the sheet are determined by the two conditions that it is a stream surface and sustains no pressure difference. Use is made of results previously obtained for the core region and the remaining finite part of the sheet is dealt with by choosing certain functions for its shape and strength.

A NEW METHOD OF OBTAINING LOWER LIMITS FOR THE SOLUTIONS OF 'EIGENVALUE' PROBLEMS FOR BEAMS AND PLATES. D. Williams. August 1957. 14p. RAE Structures 225. (Ask for N-57399*)

A new method is described for deriving lower limits for the solutions of eigenvalue problems for beams and plates. It depends on defining the deformation of an elastic system by its displacements at a discrete number of stations, and on expressing curvature in finite-difference form. A physical argument takes the place of a rigorous proof and the method is illustrated by applying it to simple eigenvalue problems of elastic instability and natural vibration frequencies for which well-known standard solutions are available for comparison.

LOW SPEED EXPERIMENTS ON THE WAKE CHARACTERISTICS OF FLAT PLATES NORMAL TO AN AIRSTREAM. R. A. Fail, J. A. Lawford, and R. C. W. Eyre. June 1957. 39p. diagrs., tabs. RAE Tech. Note Aero 2516. (Ask for N-57400*)

Experiments on isolated flat plates perpendicular to the wind are described. It is shown that the effects of aspect ratio on drag, base pressure, and flow pattern are small up to A = 10. All of these rectangular plates shed turbulent eddies at particular frequencies; generally there are two shedding frequencies for each plate, one associated with the smaller dimension of the plate, and a lower frequency associated with the larger dimension. Large changes in the shape of low-aspect-ratio plates have very small effects on the aerodynamic characteristics but perforating the plate can eliminate the regular shedding of eddies and reduce the random low-frequency velocity fluctuations.

THE CALIBRATION OF A 12 STAGE AXIAL FLOW COMPRESSOR OF 8,000 H.P. A. G. Kurn. April 1957. 18p. diagrs., photo. RAE Tech. Note Aero 2505. (Ask for N-57401*)

The calibration of the Brown-Boveri compressor, which was installed in the R.A.E. transonic wind tunnels circuit in 1955, is described. Volume flows were obtained at two stations of the compressor circuit, using measurements of mean dynamic pressure given by integrating manometers. The results from the two stations agreed generally to within ±2 percent. The usual method of presenting compressor characteristics has been used; the results then form a "family" of curves, instead of collapsing into a single curve as in the simple case. The calibration shows that the design performance of the compressor has been exceeded.

THE ROTATING FLAP AS A HIGH-LIFT DEVICE. L. F. Crabtree. APPENDIX II. D. A. Kirby. April 1957. 28p. diagrs. RAE Tech. Note Aero 2492. (Ask for N-57402*)

It is well known that a wing in an airstream can develop extremely high values of lift coefficient if it is rotated about a spanwise axis. A more practical development of this system is a fixed mainplane with a rotating trailing-edge flap. The results of some little-known German research on both systems have been collected together and are presented in compact form together with some further analysis. The emphasis is on the wing-rotating flap combination, and it is shown that this is a very attractive way of generating high lift. Some gaps in our knowledge of the device are pointed out and suggestions are made for some further research.

NOTES ON A VISIT TO THE FOKKER AIRCRAFT FACTORY SCHIPHOL, AMSTERDAM, 11TH JUNE, 1957. T. Lloyd. July 1957. 7p. RAE Tech.Note Chem.1313. (Ask for CN-57403*)

The visit was arranged to discuss the use of reinforced plastics in the manufacture of the Fokker F.27 Friendship transport aircraft. The weight breakdown of the Friendship shows that over 5 percent of its total unladen weight is made up of glass fiber reinforced plastics, but this is not the only feature which shows a marked departure from conventional orthodox design. Metal to metal bonding by the Redux process is very extensively used and in many ways follows closely the laminating techniques developed in the reinforced plastic and plywood trades. The advantages claimed for these two departures from conventional designs are: reduction in stress concentrations and consequently improved fatigue characteristics, increase in structural rigidity, reduction in sealing problems, smoother outer surfaces, and reduction in cost.

THE MECHANICAL PROPERTIES OF RR58 ALUMINIUM ALLOY SHEET (CLAD) IN TENSION AND COMPRESSION AT ROOM AND ELEVATED TEMPERATURES. D. C. Hayward. April 1957. 33p. diagrs., tabs. RAE Tech.Note Met.261. (Ask for N-57406*)

Mechanical properties of specimens taken longitudinally from clad RR58 sheet at room, 100°, 150°, 200°, 250°, and 300° C after periods of 1, 200, and 1000 hours at temperature are presented. Specimens were also tested at room temperature after being heated for similar periods to investigate for recovery of strength. Results are presented in tabular and graphical form including tensile and compressive stress-strain graphs and tangent moduli for compression. Strength at room temperature was reduced by exposure at the higher temperatures and longer exposure resulted in greater loss. Strength at elevated temperature fell progressively with rise in temperature and above 150° C longer exposure caused greater loss. Stiffness at room temperature fully recovered after even the prolonged heating at all test temperatures.

ASSESSMENT OF THE POSSIBILITY OF USING SUCTION TO INHIBIT CAVITATION ON CYLINDRICAL SECTIONS. G. E. Thomas. 1957. 18p. diagrs., tabs. ARC CP 362. (Ask for N-57446*)

This report assesses the possibility of using suction to reduce the suction peak in the pressure distribution on a body moving in a fluid, with a view to delaying the onset of cavitation. Two cases are considered: (1) flow past elliptic cylinders with suction applied over the entire forward half, and (2) flow past circular cylinders with suction applied over limited areas. Results are given of calculations made to determine the effect of varying amounts of suction as well as, in the case of (2), the added effect of changing the location and extent of the suction area. It is shown that while the onset of cavitation can be considerably delayed, the amount of suction required to effect such an improvement proves to be excessive. For this reason, it is unlikely that the method can find application, at least, not on nonlifting two-dimensional forms.

INITIAL LIFT OF FINITE ASPECT-RATIO WINGS DUE TO A SUDDEN CHANGE OF INCIDENCE. Doris E. Lehrian, National Physical Laboratory. 1957. 6p. diagrs., tabs. ARC R & M 3023; ARC 17,603. (Ask for N-57447*)

The initial lift for wings of finite aspect ratio due to a sudden unit change of incidence is considered and, by the use of the method developed in R & M 2117, the ratio of the initial to the final values of the lift is determined for rectangular wings and cropped delta wings of taper ratio 1/7. These values indicate that the initial lift may be greater than the final lift for aspect ratios $A \leq 2$. This result appears to be supported by the values of instantaneous lift which were measured for the delta wing of aspect ratio 1.2 as its incidence was rapidly changed.

SUPERSONIC FLOW PAST NARROW WINGS WITH "SIMILAR" CROSS-SECTIONS AT ZERO-LIFT. W. T. Lord and G. G. Brebner. August 1957. 55p. diagrs., tab. RAE Tech. Note Aero 2509. Supersedes RAE Tech. Memo. Aero 525.
(Ask for N-57634*)

A coordination and extension of some recent theoretical work on narrow wings at zero lift is given. The wings have arbitrary plan forms, subject to the restrictions that the trailing edges are straight and unswept, and thickness distributions which have arbitrary root profiles and cross sections, provided that each wing has "similar" cross sections at all chordwise positions. Formulas are given for the overall pressure distributions, and in particular the root pressure distributions, and the wave drags of such wings. The formulas for the root pressure

BRITISH REPORTS

distributions and wave drags are very simple and enlightening. A selection of some wings of especial interest is made; results for this selection are given in detail. A primary aim is to aid the discovery of wings which possess the properties of simple geometry, of lowish wave drag, and of having inviscid pressure distributions which are unlikely to be seriously changed by viscous effects. Although in this note the emphasis is placed on narrow wings with straight unswept trailing edges, many of the formulas presented here apply unchanged to wings with swept-forward trailing edges, provided the plan forms are smooth curves.

DRAG REDUCTION OF THIN WINGS AT SUPERSONIC SPEEDS, BY THE USE OF CAMBER AND TWIST. G. M. Roper. July 1957. 105p. diagrs., tabs. RAE Aero 2585. (Ask for N-57635*)

Camber and twist are applied to the problem of reducing the drag, due to incidence, of thin triangular or sweptback wings, at supersonic speeds, with subsonic leading edges, and supersonic or sonic trailing edges. Two cases are considered: (1) with leading-edge suction ignored, and (2) with leading suction forces included. It is found that twist, especially towards the wing tips, is more effective in reducing drag, for given lift, for the larger values of $\tan\gamma/\tan\mu$, where γ is the semiapex angle and μ is the Mach angle, and that camber is more effective for the smaller values, though, in general, the best results are obtained by a suitable combination of camber and twist.

PILOT COMBUSTION CANS EMPLOYING A LARGE SCALE RECIRCULATION FLOW PATTERN. H. G. Lyall. September 1957. 31p. diagrs. NGTE Memo. M.305. (Ask for N-57636*)

A pilot combustion can is described, suitable for use as the first stage of a ram-jet primary zone, in which the flame is stabilized by a large-scale recirculation flow pattern. The recirculation is established behind the shrouded cone which forms the front of the can, and is carefully fed from several injection stations. This system is a distinct improvement on the much used earlier first stage, the "single-row can," in that despite a reduced stability range the combustion efficiency, and thus heat release, are higher. When compared with the "pepper-pot" system in which the combustion zone is fed by many small jets, with no major flow reversal, the performance of the shrouded cone system is shown to be slightly inferior with premixed vaporized combustibles but less sensitive to the presence of liquid fuel at low inlet air temperature. Results from geometrically similar cans tested at fixed inlet temperature over a range of pressures and scales are adequately correlated by the second-order reaction rate loading parameter, Q/VP^2.

FLOW IN THE LAMINAR BOUNDARY LAYER NEAR SEPARATION. B. S. Stratford. APPENDIX I - THE SOLUTION IN THE NEIGHBOURHOOD OF THE SINGULARITY AT $x = x_0$, WITH FINITE PRESSURE GRADIENTS. G. E. Gadd, National Physical Laboratory. 1957. 27p. diagrs., tabs. ARC R & M 3002. Supersedes ARC 17,230; FM 2166. (Ask for N-57637X*)

A simple formula is derived for the separation of the laminar boundary layer. The method of derivation and a key test suggest that it should be reasonably accurate and of general application, including particularly the range of sharp pressure gradients and small pressure rises to separation. In addition, a partially new exact solution is found for the boundary-layer equations of motion; also the pressure distribution is obtained for continuously zero skin friction, this pressure distribution being expected to attain any given pressure rise in the shortest distance possible for a given laminar boundary layer provided that there is neither transition nor boundary-layer control.

THE INFLUENCE OF SOLID BOUNDARIES UPON AERODYNAMIC SOUND. N. Curle, National Physical Laboratory. February 5, 1955. 10p. ARC 17,373; FM 2188. (Ask for N-57639*)

An extension is made to Lighthill's general theory of aerodynamic sound, so as to incorporate the influence of solid boundaries upon the sound field. This influence is twofold; namely, reflection and diffraction of the sound waves at the solid boundaries, and a resultant dipole field at the solid boundaries which are the limits of Lighthill's quadrupole distribution. It is shown that these effects are exactly equivalent to a distribution of dipoles, each representing the force with which unit area of solid boundary acts upon the fluid.

NOTE ON THE CONDITIONS AT A SEPARATION POINT. G. Temple. September 10, 1957. 3p. ARC 19,520; FM 2583. (Ask for N-57642*)

It is commonly asserted in discussions of boundary-layer theory that the viscous stress vanishes at the point on the flat plate where laminar separation takes place. The author has not found any formal proof of this in the literature and therefore puts forward this elementary investigation in order to open a further discussion of this matter.

THE CALCULATION OF THE PATHS OF VORTICES FROM A SYSTEM OF VORTEX GENERATORS, AND A COMPARISON WITH EXPERIMENT. J. P. Jones, Southampton University. 1957. 16p. diagrs., photos., tabs. ARC CP 361. (Ask for N-57643*)

A method is described for the calculation of the paths of the trailing vortices from a system of counter-rotating vortex generators, and a comparison is made with some experimental results obtained in a water tunnel. The method can be adapted to other configurations of generators arranged to produce rows of vortices close to a plane surface.

A SUBSONIC LIFTING-SURFACE THEORY FOR LOW ASPECT-RATIO WINGS. C. R. Taylor, Imperial College. 1957. 20p. diagrs., tabs. ARC R & M 3051; ARC 18,142. (Ask for N-57644*)

A method is developed for determining the loading on low-aspect-ratio wings. By allowing for downstream effects on the flow at a station on the wing and for the trailing-edge condition, the method improves on R. T. Jones' theory for wings of very small aspect ratio. Calculations have been made for 13 different wings and a comparison with other methods of solution is given for some cases.

EXPERIMENTS AT M = 1.41 ON ELLIPTIC CONES WITH SUBSONIC LEADING EDGES. E. E. E. Rogers and C. J. Berry, National Physical Laboratory. 1957. 41p. diagrs., photos., tabs. ARC R & M 3042; ARC 17,929. (Ask for N-57645*)

Tests have been made on six elliptic cones forming two families of models. In the first, the vertex angle in the plane of the major axes of the elliptic cross sections was maintained constant at 60° and the ratio between the minor and major axes varied; in the second family, the minor axis was constant and the vertex angle had values of 30°, 60°, and 90°. Two cones from the first family were pressure plotted at incidences up to 15°, the resulting pressure distributions being integrated to give the lift and pressure drag arising from the curved surfaces of the cones. Lift, drag, and center-of-pressure position were measured on all but one model on a strain-gage balance. Where comparison was possible, good agreement was obtained for the lift and drag derived from the two methods.

THE TENSILE STRENGTH AT ROOM TEMPERATURE AND 300° C OF FUSION AND RESISTANCE WELDED TITANIUM Ti6Al4V ALLOY SHEET. N. J. F. Gunn and G. I. Lewis. January 1957. 13p. diagrs., photos., tabs. RAE Tech. Note Met. 255. (Ask for N-57647*)

Tests have been made on a small number of fusion and resistance welds in Ti6Al4V alloy sheet at room temperature and 300° C. At both temperatures all specimens except one showed a joint efficiency of 97 percent or greater. The strength at 300° C was found to be about 75 percent of that at room temperature irrespective of straining rate.

ELEMENTARY ESTIMATES OF PARACHUTE OPENING FORCES. M. H. L. Waters. May 1957. 37p. diagrs. RAE Tech. Note Mech. Eng. 238. (Ask for CN-57648*)

Simple assumptions of the rate of parachute inflation are used to construct data sheets for parachute maximum loads and other quantities. The aim is to present an elementary analysis in detail as a basis for future comparison with experiment. Appendices treat nonhorizontal motion of the parachute and store, and estimate the effect on the opening load, of the virtual airmass associated with the canopy. The "shock factor" as measured in wind-tunnel tests is also discussed, and the last appendix extends the method of calculation to reefed parachutes.

CURVES SUITABLE FOR FAMILIES OF AEROFOILS WITH VARIABLE MAXIMUM THICKNESS POSITION, NOSE RADIUS, CAMBER, AND NOSE DROOP. L. H. Tanner, National Physical Laboratory. 1957. 26p. diagrs. ARC CP 358. (Ask for N-57663*)

The paper shows that it is possible to design geometric curves, given by single explicit equations, and having shapes suitable for use as airfoil sections. A family of sharp-nosed sections with variable maximum thickness position is described. A method of rounding the leading edge of any sharp-nosed section is then suggested. Finally a family of curves with camber and nose droop is given. The methods used could be adapted to produce other section variations if required.

SUPERSONIC BANGS. P. Sambasiva Rao, Manchester University. March 2, 1955. 27p. diagrs. ARC 17,427; FM 2194. (Ask for N-57725*)

In this paper a nonlinear theory of the supersonic bangs from an accelerating body is worked out, using an extension of Whitham's method. The strength of the bow shock is determined, and it is shown that the effect of acceleration on the pressure rise is appreciable at large distances from the nose for Mach numbers near unity. The results are compared with those of linear theory; the estimate for the pressure rise is found to be about a half of the linear value. The results also include an expression for the curvature of an attached shock at the nose, and a formula for the decay of a shock after it is detached from a decelerating body.

SOME FURTHER JET FLAP EXPERIMENTS.
N. A. Dimmock. 1957. 70p. diagrs., photos., tabs.
ARC CP 345. (Ask for N-57730X*)

This paper. which may be considered as an addendum to the NGTE Report R.175, records the results of tests on the same two-dimensional airfoil which was used for the earlier work and which had a 12.5-percent-thick elliptical cross section with a narrow full span jet slot. This time, however, the jet deflection is 58.1° from the chord line. In addition to the measurement of the forces and moments acting on the model, the flow pattern in the vicinity of the airfoil was revealed with smoke filaments and was recorded photographically. A comparison with the theory of reference 2 is drawn where appropriate and additional support is given to the thrust hypothesis. A check on the effects of Reynolds number variation and of the addition of transition wires to the model confirmed the results of the previous experiments, while the influence of ground proximity on the lift, center of lift position, and the thrust was investigated and found to be substantial, although a reason is suggested why these results might be pessimistic.

A SIMPLE METHOD OF IMPROVING THE SUPERSONIC VELOCITY DISTRIBUTION IN A TRANSONIC TUNNEL HAVING SLOTTED WALLS. C. N. Hall. July 1957. 13p. diagrs., photo. RAE Tech. Note Aero 2517. (Ask for N-57773*)

This note describes how the center-line distribution of Mach number in the R. A. E. 8 ft x 6 ft transonic tunnel has been modified at supersonic speeds by means of curved lengths of perforated steel plate set behind a proportion of the suction slots in the walls of the working section. It was found that the slope and curvature of the perforated strips and the distance from the suction slots determined their effect on the distribution of Mach number. A form of plate was evolved which reduced the variation of Mach number about the mean from ±0.010 to ±0.006 at the maximum Mach number.

BOUNDARY LAYER MEASUREMENTS ON 15° AND 24.5° CONES AT SMALL ANGLES OF INCIDENCE AT M = 3.17 AND 3.82 AND ZERO HEAT TRANSFER. F. V. Davies and R. J. Monaghan. June 1957. 40p. diagrs., photos. RAE Aero 2577. (Ask for N-57774*)

The transition front was extremely sensitive to α, a fourfold variation occurring between transition RN on the leeward and windward sides of the 15° cone at $\alpha = 2°$. At zero α the transition RN was between 2.5 and 3.0 x 10^6 and no significant variation was observed over the test range of stagnation pressures from 2 to 5 atmospheres. Pitot traverses on the top generator of the 15° cone at $M_\infty = 3.17$ showed that the effects of small α on the characteristics of the laminar boundary layer were nearly linear. Small α altered the thicknesses of both laminar and turbulent boundary layers, but did not affect the shapes of the velocity profiles. The alteration with α of the displacement thickness of the laminar boundary layer was large (agreeing with Moore's theory) and in amount was more than twice that found with a turbulent boundary layer.

A description is given of an intermittent hypersonic tunnel having a running time of hundreds of milliseconds. The tunnel employs a gun as a compressor. A light piston is driven at supersonic velocity in a closed barrel, and the miltiple shock reflections between the piston and the closed end of the barrel provide a high temperature, high pressure stagnation region of gas, which is allowed to expand through a convergent-divergent nozzle when the piston has come to rest. A theoretical study is given of the piston motion and of the shock-reflection process. It is shown that perfect gas stagnation temperatures up to 10,000° K are possible if a light gas such as hydrogen is used to drive the tunnel. Tunnel instrumentation is discussed, and some measurements of flow quantities in the tunnel are presented.

To date most research activity on short take-off and vertical take-off aircraft has been directed toward the development of basic configurations to achieve the required performance. This paper discusses the low-speed control problems of such aircraft, to which little effort has been applied until recently.

N-52867X

Advisory Group for Aeronautical Research and Development. A FLIGHT TECHNIQUE FOR THE MEASUREMENT OF THRUST BOUNDARIES AND OF DRAG DUE TO LIFT. H. D. Rylands. (Presented at 10th meeting of AGARD Flight Test Panel, May 20-24, 1957, London.) May 1957. v, 14p. diagrs. AGARD Report 123. (Ask for N-52867X)

None of the existing methods of measuring thrust boundaries is suitable for use with the new high-performance aircraft. A new technique is therefore proposed which is acceptable for supersonic aircraft and which will also have many advantages over existing methods for use with subsonic types. Some data on drag due to lift can also be obtained without the need for thrust measurement. Preliminary flight trials on a subsonic aircraft proved very satisfactory. No major difficulties are anticipated when the technique is applied to supersonic aircraft.

N-52875X

Advisory Group for Aeronautical Research and Development. SOME REMARKS UPON THE PROBLEM OF TEMPERATURE SHOCK IN AIRCRAFT. F. Bollenrath. (Presented at 4th meeting of AGARD Structures and Materials Panel, August 27-31, 1956, Brussels, Belgium.) August 1956. vi, 12p. diagrs., tabs. AGARD Report 90. (Ask for N-52875X)

An account is given of the structural problems associated with heating and large temperature gradients. The thermal stresses due to a nonstationary distribution of temperature are calculated for a plate cooled on one surface and heated on the other by a gas moving at high speed. The cases where the plate is completely free or completely restrained in one direction are discussed. Formulas are obtained which, under these conditions of restraint, make a quick comparison of different materials possible. Possible lines for the extension of theoretical and experimental work are suggested.

N-53979X

Advisory Group for Aeronautical Research and Development. THE USE OF GUN-LAUNCHED MODELS FOR EXPERIMENTAL RESEARCH AT HYPERSONIC SPEEDS. Alvin Seiff, NACA. (Presented at 11th meeting of AGARD Wind Tunnel and Model Testing Panel, July 8-12, 1957, Scheveningen, Holland.) July 1957. v, 19p. diagrs., photos. AGARD Report 138. (Ask for N-53979X)

The difficulty in obtaining hypersonic air flows with Mach numbers in excess of 10 has led to a concerted effort at the Ames Laboratory of the NACA for the development of gun-launched model flight tests for this speed range. As ordinary guns are normally limited to launching speeds of about 6,000 ft/sec, two ways of extending gun-launched model tests farther into the hypersonic Mach number range have been exploited. One is to use a counter-current supersonic airstream flowing opposite to the free-flying model, by means of which a Mach number of 13 can be attained. The second approach is to replace powder gas as a propellant in guns by compression-heated helium. In this way, short, lightweight projectiles have been propelled at speeds in excess of 17,000 ft/sec. In combination, the high-performance gun and the counter-current airstream give still higher Mach numbers, of the order of 25.

N-54976X

Advisory Group for Aeronautical Research and Development. THE HYPERSONIC FACILITY OF THE POLYTECHNIC INSTITUTE OF BROOKLYN AND ITS APPLICATION TO PROBLEMS OF HYPERSONIC FLIGHT. Antonio Ferri and Paul A. Libby. (Presented at 11th meeting of AGARD Wind Tunnel and Model Testing Panel, July 8-12, 1957, Scheveningen, Holland.) July 1957. vii, 39p. diagrs. AGARD Report 136. (Ask for N-54976X)

The engineering problems connected with hypersonic flight are reviewed. The utilization of a hypersonic wind tunnel with stagnation temperatures of 3000° to 5000° R for the solution of these problems is discussed. It is shown that for most problems presently considered important, such a wind tunnel can provide the means for investigation. The hypersonic facility of the Polytechnic Institute of Brooklyn is described; the design considerations of the heating system and the demonstrated and expected performance are presented. Finally, some of the testing techniques developed in connection with conventional testing at a Mach number of 6 and with shrouded model testing are reviewed.

(Presented at 5th meeting of AGARD Structures and Materials Panel, April 24-27, 1957, Oslo, Norway.) April 1957. v, 33p. diagrs., photos. AGARD Report 96. (Ask for CN-55019X)

A description is given of the problems encountered and the techniques evolved for their solution during the manufacture of some 2,000 airplanes incorporating about a million pounds of titanium in their designs. Primary emphasis is given to titanium-alloy sheet applications.

CN-55022X

Advisory Group for Aeronautical Research and Development. PRODUCTION PROBLEMS OF TITANIUM AND ITS ALLOYS. E. Swainson and R. L. P. Berry, Imperial Chemical Industries Ltd. (Presented at 5th meeting of AGARD Structures and Materials Panel, April 29-May 3, 1957, Copenhagen, Denmark.) April-May 1957. v, 29p. diagr., photos. AGARD Report 95. (Ask for CN-55022X)

Discusses the present state of knowledge in certain aspects of titanium technology and gives some indication of the possible pattern of future developments. The aspects discussed include the problems of reducing the ore to a metal of sufficiently low oxygen content to have adequate ductility and alloying capabilities, melting in the absence of air and without contamination from furnace refractories and other sources, realization of the full alloying potential of the metal, fabrication of ingots of high strength alloy compositions into the various semifinished forms required, and reclamation of titanium scrap.

Advisory Group for Aeronautical Research and Development. ALUMINIUM ALLOYS IN AIRCRAFT STRUCTURES. G. Meikle, United Kingdom. (Presented at 5th meeting of AGARD Structures and Materials Panel, April 24-27, 1957, Oslo, Norway.) April 1957. iv, 11p. diagrs., photos. AGARD Report 102. (Ask for N-55023X)

Details of compositions of three groups of aluminum alloys used in the United Kingdom are discussed in relation to alloys used in the U. S. A. The properties of these alloys at elevated temperatures are mentioned particularly with regard to the effect of time and temperature, this being of great importance where kinetic heating is involved. The different

MISCELLANEOUS

nominal compositions of the high strength aluminum-zinc-magnesium alloys used in the United Kingdom are dealt with and some of the difficulties experienced with stress-corrosion in this type of alloy are mentioned. Research at the Royal Aircraft Establishment on this problem is briefly mentioned with particular reference to the effect of chemical composition and heat treatment. Brief reference is made to a possible aluminum alloy for use at temperatures up to 200° C.

Polytechnic Institute of Brooklyn. VIBRATIONS OF A HELICOPTER ROTOR-FUSELAGE SYSTEM INDUCED BY THE MAIN ROTOR BLADES IN FLIGHT: A THREE-DIMENSIONAL MODEL INCLUDING DAMPING. M. Morduchow and A. Muzyka. May 1957. 70p. diagrs., tabs. Polytechnic Inst. of Brooklyn. PIBAL Report 401. (Ask for N-57722*)

The response of the hub and fuselage of a helicopter to harmonic forces transmitted by the rotor blades to the hub is derived on the basis of a simplified three-dimensional dynamical model of the hub-fuselage structure in flight. Hub and fuselage displacements and external exciting forces both in and normal to the rotor plane of rotation are considered. Explicit expressions for these displacements in terms of appropriate hub and fuselage natural frequency and mass parameters are obtained, and explicit conditions of resonance are determined. The effect of internal damping is analyzed and comparatively simple expressions are derived for the maximum displacements of the hub-fuselage structure with damping. Numerical examples are given throughout to illustrate the results.

NACA RM A52A31

WING LOAD DISTRIBUTION ON A SWEPT-WING AIRPLANE IN FLIGHT AT MACH NUMBERS UP TO 1.11 AND COMPARISON WITH THEORY. L. Stewart Rolls and Frederick H. Matteson. April 1952. 73p. diagrs., photos., tabs. (NACA RM A52A31)

Flight tests were made to determine the pressure distribution on the wing of an F-86 airplane over the flight range of lift coefficients for Mach numbers up to 1.11. Comparisons are made between the results and subsonic and supersonic theories for the spanwise distribution of loading. Tuft studies are used in conjunction with the buffeting and aileron floating characteristics to explain variations in the measured loading.

NACA RM A53A30

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS. Charles F. Hall. April 1953. 132p. diagrs., tabs. (NACA RM A53A30)

Results are presented, in graphical and tabular form, from a wind-tunnel investigation of the lift, drag, and pitching-moment characteristics of thin, low-aspect-ratio wings in combination with a body at Mach numbers from 0.25 to as high as 1.9. The following are analyzed and compared with existing theoretical results: (1) effects of aspect ratio on 3-percent-thick triangular wings; (2) effects of plan form on 3-percent-thick triangular, sweptback, and unswept wings of aspect ratios 2 and 3; (3) effects of wing thickness on triangular wings of aspect ratio 2; (4) effects of profile shape on triangular, sweptback, and unswept wings; and (5) effects of camber and twist on triangular wings of aspect ratios 2 and 4.

NACA RM A54A04

EFFECT OF NOSE SHAPE AND TRAILING-EDGE BLUNTNESS ON THE AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT WING OF ASPECT RATIO 3.1, TAPER RATIO 0.4, AND 3-PERCENT THICKNESS. John C. Heitmeyer. March 1954. 36p. diagrs., tabs. (NACA RM A54A04)

The effects of blunting the trailing edge and/or rounding the leading edge upon the lift, drag, and pitching-moment characteristics of a wing-body combination, employing a plane tapered wing of aspect ratio 3.1 with 3-percent-thick biconvex sections, have been experimentally determined at Mach numbers from 0.61 to 0.91 and 1.20 to 1.90. Trailing-edge thicknesses from 0.3 to full maximum section thickness are considered.

NACA RM A54L27

A FLIGHT INVESTIGATION AT TRANSONIC SPEEDS OF A MODEL HAVING A TRIANGULAR WING OF ASPECT RATIO 4. Loren G. Bright. March 1955. 40p. diagrs., photos., tabs. (NACA RM A54L27)

The longitudinal aerodynamic characteristics of a model having an aspect-ratio-4 triangular wing and a 45° sweptback horizontal tail mounted in the extended wing chord plane were investigated at transonic speeds by the free-falling recoverable model technique. Static- and dynamic-stability data, and load-distribution data are presented for Mach numbers from 0.88 to 1.14 and angles of attack from -1° to about $+8^{\circ}$ to $+21^{\circ}$, depending on the Mach number.

NACA RM A55A03

EFFECTS OF SWEEP AND TAPER RATIO ON THE LONGITUDINAL CHARACTERISTICS OF AN ASPECT RATIO 3 WING-BODY COMBINATION AT MACH NUMBERS FROM 0.6 TO 1.4. Earl D. Knechtel and James L. Summers. March 1955. 36p. diagrs., photo. (NACA RM A55A03)

An experimental investigation has been made to determine the effects of sweep and taper ratio on the longitudinal characteristics of a wing-body combination at Mach numbers from 0.6 to 1.4 at 1.5×10^{6} Reynolds number. The wings were 3 percent thick and of aspect ratio 3. Leading-edge sweep angle was varied from 19.1° to 53.1° for a constant taper ratio of 0.4, and taper ratio was varied from 0 to 0.4 for a constant sweep angle of 53.1°.

NACA RM E9I16

ALTITUDE-WIND-TUNNEL INVESTIGATION OF TAIL-PIPE BURNER WITH CONVERGING CONICAL BURNER SECTION ON J35-A-5 TURBOJET ENGINE. H. Carl Thorman and Carl E. Campbell. February 10, 1950. 60p. diagrs., photos., tab. (NACA RM E9I16)

Investigation of tailpipe burning was conducted in Lewis altitude wind tunnel using full-scale turbojet engine and tailpipe burner designed for specific airplane. Three fuel patterns and three flame holders were investigated using fixed-area exhaust nozzle. Tailpipe shell cooling was accomplished by means of inner liner. Burner performance, overall performance, and combustion blowout limits are presented and discussed. Most efficient burner performance and widest range of operable fuel-air ratios were obtained with configurations in which fuel injectors that gave relatively uniform distribution of tailpipe fuel-air mixture were used with annular-V-gutter type flame holders blocking about 30 percent of burner cross-sectional area.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E50A19

ALTITUDE PERFORMANCE AND OPERATIONAL CHARACTERISTICS OF 29-INCH-DIAMETER TAILPIPE BURNER WITH SEVERAL FUEL SYSTEMS AND FUEL-COOLED STAGE-TYPE FLAME HOLDERS ON J35-A-5 TURBOJET ENGINE. Richard L. Golladay and Harry E. Bloomer. April 28, 1950. 57p. diagrs., photos., tab. (NACA RM E50A19)

An investigation of tailpipe burning was conducted in the NACA Lewis altitude wind tunnel with a full-scale turbojet engine and a 29-inch-diameter tailpipe burner. Effects of fuel distribution and number and arrangement of stages on performance and operational characteristics of several fuel-cooled flame holders are presented and discussed. Operation with a three-stage flame holder having the large stage upstream was the most efficient. Combustion efficiency was slightly increased at high altitudes by injecting fuel upstream of the flame holder.

NACA RM E52I25

TURBOJET COMBUSTOR EFFICIENCY WITH CERAMIC-COATED LINERS AND WITH MECHANICAL CONTROL OF FUEL WASH ON WALLS. Helmut F. Butze and Edmund R. Jonash. November 1952. 43p. photos., diagrs., tabs. (NACA RM E52I25)

Two methods of decreasing losses of unevaporated fuel from the combustion zone of turbojet-engine combustors were investigated: installing fuel dams on the inner surface of a J33 combustor liner to divert liquid-fuel films on the walls into penetrating air jets and coating the liner wall of a J33 and a J47 single combustor with ceramic to increase surface temperature and hence rate of evaporation of fuel. Installation of fuel dams brought about a substantial increase in combustion efficiency at low fuel flows; no increase was observed at high fuel-flow rates. Similar results were obtained in another J33 combustor, the liner of which was coated with a dual ceramic coating. No further improvements in combustion efficiency resulted from a combination of fuel dams and ceramic coating. Only small effects on combustion efficiency were noted when two other types of ceramic coating were applied to the J33 combustor or when the dual ceramic coating was applied to the J47 combustor.

NACA RM E52J07

ALTITUDE PERFORMANCE INVESTIGATION OF TWO SINGLE-ANNULAR TYPE COMBUSTORS AND THE PROTOTYPE J40-WE-8 TURBOJET ENGINE COMBUSTOR WITH VARIOUS COMBUSTOR INLET-AIR PRESSURE PROFILES. Adam E. Sobolewski, Robert R. Miller, and John E. McAulay. May 1953. 46p. diagrs., photos., tab. (NACA RM E52J07)

Data obtained for three single-annular type combustors over a range of engine speeds at an altitude of 30,000 feet and flight Mach number of 0.62 indicated that changes in combustor hole geometry and combustor-inlet air-pressure profiles affected the combustor-outlet temperature profile and the combustor pressure-loss coefficient but had no discernible effect on combustion efficiency. Performance data for the prototype J40-WE-8 turbojet-engine combustor were obtained over a range of altitudes from 15,000 to 55,000 feet and flight Mach numbers from 0.17 to 0.99. A good correlation was obtained when combustion efficiency was presented as a function of a combustion parameter and engine fuel-air ratio.

NACA RM E52K21

PRELIMINARY INVESTIGATION OF A CHEMICAL STARTING TECHNIQUE FOR THE ACID GASOLINE ROCKET PROPELLANT SYSTEM. Glen Hennings and Gerald Morrell. January 1953. 23p. photo., diagrs., tab. (NACA RM E52K21)

A preliminary investigation of chemical starting of the acid - gasoline system in a 200-pound-thrust rocket engine indicated that transition to gasoline could be obtained at -40° F provided a small quantity of gasoline was suspended in the hydrazine hydrate igniter fluid. Blends of triethylamine and aromatic amines were found to ignite at -85° F with specially blended red fuming nitric acid, but at this temperature, transition was obtained only when the running fuel was triethylamine.

NACA RM E52L22a

DESIGN AND TEST OF MIXED-FLOW IMPELLERS. III - DESIGN AND EXPERIMENTAL RESULTS FOR IMPELLER MODEL MFI-2A AND COMPARISON WITH IMPELLER MODEL MFI-1A. Joseph T. Hamrick, Walter M. Osborn, and William L. Beede. March 1953. 34p. diagrs., photo., tab. (NACA RM E52L22a)

A mixed-flow impeller was designed to give a prescribed blade-surface velocity distribution at mean blade height for a given hub-shroud profile. The blade shape at mean blade height, which was produced by the prescribed velocity distribution, was extended by means of radial lines to form the composite blade shape from hub to shroud. The resulting blade was relatively thick; therefore, it was necessary to retain the inverse blade taper which resulted from extension of the radial lines in order to prevent merging or near merging of the separate blades near the hub. For the first test version of the impeller, designated the MFI-2A, the blade

UNAVAILABLE; contains proprietary or obsolete information.

DECLASSIFIED NACA RESEARCH REPORTS

height was arbitrarily made greater than that for the basic impeller (the MFI-2) to allow for viscous effects. At design equivalent speed of 1400 feet per second the peak pressure ratio and maximum adiabatic efficiency were 3.95 and 79 percent, respectively. The adiabatic efficiency of the MFI-2A is four points lower than that for impeller model MFI-1A, but because of the higher slip factor for the MFI-2A, the pressure ratios are approximately equal. The procedures followed in the design of the MFI-1A and MFI-2A were, in general, the same; and, although the prescribed initial condition resulted in geometrical configurations that were quite dissimilar, the resulting performance characteristics compare favorably with designs for which considerable development work has been necessary.

NACA RM E53A12

INVESTIGATION OF PRESSURE RECOVERY OF A SINGLE-CONICAL-SHOCK NOSE INLET AT MACH NUMBER 5.4. Harry Bernstein and Rudolph C. Haefeli. April 1953. 22p. diagrs., photos. (NACA RM E53A12)

An experimental investigation of the performance of a single-conical-shock diffuser was conducted at a Mach number of 5.4 and a Reynolds number based on model diameter of 375,000. Total-pressure recoveries of 13.7 and 13.1 percent were obtained at angles of attack of 0° and 3°, respectively. The corresponding kinetic energy efficiencies were 86.4 percent at an angle of attack of 0° and 86.0 percent at an angle of attack of 3°.

NACA RM E53A30

EFFECT OF DIFFUSER DESIGN, DIFFUSER-EXIT VELOCITY PROFILE, AND FUEL DISTRIBUTION ON ALTITUDE PERFORMANCE OF SEVERAL AFTERBURNER CONFIGURATIONS. E. William Conrad, Frederick W. Schulze, and Karl H. Usow. July 1953. 63p. diagrs., photos., tab. (NACA RM E53A30)

An investigation was conducted in the NACA Lewis altitude wind tunnel to improve the altitude performance and operational characteristics of an afterburner primarily by modifying the diffuser-exit velocity profile by changes in diffuser design and by changing the fuel distribution and the flame holder. Twenty configurations, consisting of combinations of six diffuser geometries, six flame-holder types, and twelve fuel systems, were investigated. Data were obtained over a range of afterburner fuel-air ratios at diffuser-inlet total pressures from 2750 to 620 pounds per square foot. Variations of the velocity profile produced the greatest effect on afterburner combustion efficiency at the pressure level of 620 pounds per square foot. Changes in fuel distribution affected the fuel-air ratio at which peak combustion efficiency occurred as well as the efficiency level. Screeching combustion, which was most prevalent at low altitudes and medium-to-high fuel-air ratios, imposed a restriction on the operable range of a number of configurations.

NACA RM E53F23

INVESTIGATION OF A SUPERSONIC-COMPRESSOR ROTOR WITH TURNING TO AXIAL DIRECTION. I - ROTOR DESIGN AND PERFORMANCE. Edward R. Tysl, John F. Klapproth, and Melvin J. Hartmann. August 1953. 36p. diagrs., photos. (NACA RM E53F23)

An approximate, quasi-three-dimensional design method was adapted to the design of impulse-type supersonic compressors. The method was applied to the design of a compressor rotor having a tip speed of 1600 feet per second, an inlet hub-tip radius ratio of 0.75, and an axial discharge relative to the rotor. Tests of the rotor as a separate component at 97.5 percent of the equivalent design condition in Freon-12 produced a total-pressure ratio of 5.7 at an adiabatic efficiency of 0.89. The absolute mean-radius discharge Mach number was 1.93.

NACA RM E53L02

DESIGN AND TEST OF MIXED-FLOW IMPELLERS. IV - EXPERIMENTAL RESULTS FOR IMPELLER MODELS MFI-1 AND MFI-2 WITH CHANGES IN BLADE HEIGHT. Joseph T. Hamrick, William L. Beede, and Joseph R. Withee, Jr. February 1954. 32p. diagrs., photos. (NACA RM E53L02)

Modifications A and B of impeller model MFI-1 and A, B, and C of impeller model MFI-2 were investigated experimentally in an attempt to determine what allowance in blade height should be made for boundary layer and viscous losses in an impeller designed for isentropic compressible flow. A gradual increase in blade height was arbitrarily made from inlet to outlet in anticipation of a gradual buildup of boundary layer. Apparently there was a rapid buildup of boundary layer near the inlet in the experimental case rather than a gradual one. Therefore, the proper allowance for boundary layer cannot be prescribed from the data obtained. Decreasing the pressure gradient along the shroud by reducing the blade height allowance apparently did little to increase the overall efficiency. At the design speed of 1400 feet per second, the overall adiabatic efficiency was increased from 0.83 for the MFI-1A to 0.85 for the MFI-1B with reduction in height; however, it is indicated from the theoretical velocity distribution and outlet surveys that the increase was due to a change from decelerating to accelerating flow along the hub rather than from any change along the shroud. It is further indicated that the consequences of a thickened or separated boundary layer depend not only on the design velocity gradients but also on the shape of the passage.

NACA RM E53L24

INVESTIGATION OF A SUPERSONIC-COMPRESSOR ROTOR WITH TURNING TO AXIAL DIRECTION. II - ROTOR COMPONENT OFF-DESIGN AND STAGE PERFORMANCE. Melvin J. Hartmann and Edward R. Tysl. March 1954. 31p. diagrs., photos. (NACA RM E53L24)

Analysis of the complete performance of an impulse-type supersonic-compressor rotor with turning to the axial direction indicated that the best stage performance would probably be obtained at an intermediate

DECLASSIFIED NACA RESEARCH REPORTS

rotor-discharge Mach number rather than at the design impulse condition. The matching of the operational points of the rotor and stators is rather critical. The stators designed for this investigation caused the rotor to operate at a discharge Mach number that is too low for good stage performance. It was indicated that the rotor and stator matching could be improved at part speed by decreasing the stator angles below the design setting. Decreasing the stator angle 6° resulted in a stage total-pressure ratio of 2.7 and a stage adiabatic efficiency of 0.77.

NACA RM E54A18

PRELIMINARY INVESTIGATION OF PUMPING AND THRUST CHARACTERISTICS OF FULL-SIZE COOLING-AIR EJECTORS AT SEVERAL EXHAUST-GAS TEMPERATURES. W. K. Greathouse. April 1954. 130p. diagrs., photos., tab. (NACA RM E54A18)

An experimental investigation was made to determine the performance of seven full-size ejector configurations operating over a range of secondary to primary air-flow ratio from zero to about 0.30 at primary total- to ambient-pressure ratios up to 5.0 with various primary gas temperatures from 1120° to 3700° R. Diameter ratios of 1.048, 1.095, 1.195, and 1.60 were tested with cylindrical-type ejector shrouds, and a diameter ratio of 1.10 was tested with a conical-type shroud. Spacing ratio varied from 0.213 to 0.810. Pumping characteristics of cylindrical-type ejectors having a short spacing ratio relative to the diameter ratio were generalized by the corrected weight-flow ratio parameter $(W_s/W_p)\sqrt{T_s/T_p}$. The total variation in gross ejector thrust ratio with primary gas temperature did not exceed 5 percent for any one ejector investigated when compared over a range of corrected weight-flow ratio at the primary pressure ratio of 5.0.

NACA RM E54A20

APPLICATION OF RADIAL-EQUILIBRIUM CONDITION TO AXIAL-FLOW TURBOMACHINE DESIGN INCLUDING CONSIDERATION OF CHANGE OF ENTROPY WITH RADIUS DOWNSTREAM OF BLADE ROW. James E. Hatch, Charles C. Giamati, and Robert J. Jackson. April 1954. 52p. diagrs. (NACA RM E54A20)

An investigation was made of the validity of application of the simplified-radial-equilibrium equation to axial-flow turbomachines. Data from axial-flow compressors were compared with two types of calculations of radial variations of axial velocity, one type including the measured radial variation of stagnation-pressure losses by means of a radial-entropy gradient term in the radial-equlibrium equation and the other type excluding this term. In order to compute accurately the radial variation of velocities at an axial station following several stages of a multistage compressor, or in the boundary-layer regions of a compressor, it was necessary to include the entropy term in the simplified-radial-equilibrium equation. A velocity-diagram design method including the effect of estimated stagnation pressures on the design axial-velocity profile is presented.

NACA RM E54G13

PERFORMANCE OF A 16-INCH RAM-JET ENGINE WITH A CAN-TYPE COMBUSTOR AT MACH NUMBERS OF 1.50 TO 2.16. Donald P. Hearth and Eugene Perchonok. August 1954. 30p. diagrs. (NACA RM E54G13)

Combustor, engine, and inlet data were obtained over a fuel-air-ratio range of from 0.018 to 0.070. Angle-of-attack data to 10° are presented at Mach numbers of 1.50, 1.79, and 1.98. Results indicated that the combustion efficiencies were generally unaffected by free-stream Mach number and varied between 60 and 90 percent with JP-4 fuel. Combustor operation at 10° angle of attack was satisfactory except under subcritical diffuser operation at Mach number 1.98.

NACA RM E55A04

EFFECTS OF INLET-AIR-FLOW DISTORTION ON STEADY-STATE ALTITUDE PERFORMANCE OF AN AXIAL-FLOW TURBOJET ENGINE. William Conrad, Morgan P. Hanson, and John E. McAulay. September 1955. 47p. diagrs., photo. (NACA RM E55A04)

An investigation was conducted in an NACA altitude test chamber to determine the effects of radial and circumferential distortions of the inlet air on the steady-state performance of an axial-flow engine and its components. Radial distortions up to 17 percent of the average inlet total pressure and circumferential distortions up to 26 percent were imposed. Data were obtained at altitudes from 15,000 to 50,000 feet at a flight Mach number of 0.8. Compared on the basis of equal average values of compressor-inlet total pressure, the maximum loss in net thrust was 14 percent.

DESIGN AND TEST OF MIXED-FLOW IMPELLERS. V - DESIGN PROCEDURE AND PERFORMANCE RESULTS FOR TWO VANED DIFFUSERS TESTED WITH IMPELLER MODEL MFI-1B. Joseph T. Hamrick and Walter M. Osborn. July 1955. 32p. diagrs., photos. (NACA RM E55E13)

The design procedure and experimental test results for a range of impeller speeds are presented for two vaned diffusers of 24 and 40 vanes. Both were designed to give approximately the same velocity distribution on the vane surfaces. A maximum efficiency of 0.78 for a pressure ratio of 3.25 at a mean outlet speed of 1300 ft/sec was obtained for both diffusers. The maximum efficiency at the design speed of 1400 ft/sec was 0.77 at a pressure ratio of 3.73 for both diffusers.

NACA RM E55E16

EFFECTIVENESS OF A TURBOJET TUBULAR COMBUSTOR IN SCREENING THE TURBINE FROM FOREIGN OBJECTS. Patrick T. Chiarito. July 1955. 20p. diagrs., photos. (NACA RM E55E16)

The effectiveness of a tubular combustor in screening the turbine from foreign objects used in these tests was measured to be 36 percent (that is, on the average, 64 percent of the objects used in the tests penetrated the production combustor). The screening effectiveness of this type combustor may be improved by moving the bellows housing aft and radially outward. Wire screens mounted over the air-intake holes reduced the penetration of objects that were even smaller than the screen openings. A fine-mesh screen wrapped around the liner prevented penetration. The maximum pressure loss due to the screens was about 1/2 percent of the total pressure at the combustor inlet.

NACA RM E55F23

DESIGN AND TEST OF MIXED-FLOW IMPELLERS. VI - PERFORMANCE OF PARABOLIC-BLADED IMPELLER WITH SHROUD REDESIGNED BY RAPID APPROXIMATE METHOD. Kenneth J. Smith and Walter M. Osborn. September 1955. 22p. diagrs., photo., tab. (NACA RM E55F23)

A centrifugal impeller was modified by a newly developed design procedure that reduced the velocity gradients from inlet to outlet along the hub contour. The experimental test results for the modified impeller are compared with those of the original impeller. At a speed of 1500 feet per second, the peak pressure ratio and maximum efficiency were 4.03 and 0.800, respectively. The maximum efficiency points for the speed range 900 to 1500 feet per second were between 0.854 and 0.800. The modified impeller had higher efficiencies than the original impeller at all speeds tested, with a gain in efficiency of 0.195 (0.605 to 0.800) at 1500-feet-per-second equivalent speed.

NACA RM E55L13

EVALUATION OF AN AUTOMATIC INLET-PRESSURE CONTROL VALVE FOR STUDY OF TRANSIENT ENGINE PERFORMANCE CHARACTERISTICS. Lewis E. Wallner, Robert J. Lubick, and Harry E. Bloomer. April 1956. 25p. diagrs., photo. (NACA RM E55L13)

An evaluation of data obtained with an automatic constant-inlet-pressure control valve designed to facilitate the study of transient engine performance characteristics was made in the Lewis altitude wind tunnel. During acceleration, inlet total-pressure deviations of about 5 percent from the desired level were obtained with the proportional-type control. When integrating action was added to the control, this pressure deviation was reduced to 1-1/2 percent. The engine transient and surge characteristics obtained with the automatic inlet-pressure valve were about the same as those obtained with the bellmouth-inlet installation.

NACA RM E55L15

DESIGN AND TEST OF MIXED-FLOW IMPELLERS. VII - EXPERIMENTAL RESULTS FOR PARABOLIC-BLADED IMPELLER WITH ALTERNATE BLADES CUT BACK TO FORM SPLITTER VANES. Walter M. Osborn. March 1956. 13p. diagrs., photo. (NACA RM E55L15)

A centrifugal impeller was altered by cutting back every other blade to form a splitter-vaned impeller. The experimental test results for the splitter-vaned impeller are compared with those of the fully bladed impeller. At a speed of 1500 ft/sec, the peak pressure ratio and maximum efficiency were 4.03 and 0.780, respectively. The maximum-efficiency points for the speed range of 900 to 1500 ft/sec were between 0.780 and 0.825. The splitter-vaned impeller had a higher weight-flow range but lower peak pressure ratios and maximum efficiencies than the fully bladed impeller.

NACA RM E56A16

INTERACTION OF AN EXHAUST JET AND ELEMENTARY CONTOURED SURFACES LOCATED IN A SUPERSONIC AIR STREAM. Joseph F. Wasserbauer and Gerald W. Englert. April 1956. 20p. diagrs., photo. (NACA RM E56A16)

A study of the forces on simple contoured surfaces near an exhaust jet was made at a free-stream Mach number of 1.6 over a range of nozzle pressure ratios. The surfaces were located at two fixed positions from the nozzle center line. Also investigated was the influence on the forces of the fairings between these surfaces and the boattail housing the exhaust nozzle. Varying the wedge angle, radius of curvature, and arc length of the various surfaces affected the normal-force coefficient. Addition of fairings changed normal forces and center-of-pressure locations.

DESIGN AND TEST OF MIXED-FLOW IMPELLERS. VIII - COMPARISON OF EXPERIMENTAL RESULTS FOR THREE IMPELLERS WITH SHROUD REDESIGNED BY RAPID APPROXIMATE METHOD. Walter M. Osborn, Kenneth J. Smith, and Joseph T. Hamrick. February 1957. 32p. diagrs., photos. (NACA RM E56L07)

Three centrifugal impellers with parabolic, circular, and skewed-parabolic blading were modified by a newly developed design procedure to reduce the velocity gradients from inlet to outlet along the hub contour. The experimental test results for the modified impellers are compared with those of the original impellers. The modified impellers had higher efficiencies than the original impellers at all speeds tested, with the largest gains in efficiency at 1300 feet per second and higher. Of the three modified impellers, the parabolic-bladed had the highest maximum efficiencies (0.854 to 0.800) over the speed range tested.

NACA RM H55A17

LATERAL STABILITY AND CONTROL CHARACTERISTICS OF THE CONVAIR XF-92A DELTA-WING AIRPLANE AS MEASURED IN FLIGHT. Thomas R. Sisk and Duane O. Muhleman. May 1955. 55p. diagrs., photos., tabs. (NACA RM H55A17)

The lateral stability and control characteristics of the Convair XF-92A delta-wing airplane are determined from sideslips, aileron rolls, and rudder pulses. A limited amount of data with wing fences installed at 60 percent of the wing semispan is presented for comparison with the basic airplane configuration.

NACA RM H56A06

AN ANALOG STUDY OF THE RELATIVE IMPORTANCE OF VARIOUS FACTORS AFFECTING ROLL COUPLING. Joseph Weil and Richard E. Day. April 1956. 81p. diagrs., photo., tabs. (NACA RM H56A06)

An analog study of the roll coupling problem has been made for a representative swept-wing and a tailless delta-wing configuration. The investigation, conducted primarily for subsonic flight conditions, included determination of the effects of wide variations in many of the pertinent aerodynamic derivatives on the motions developed in rolling maneuvers. The influence of large changes in principal axis inclination and mass distribution was also considered.

NACA RM L53A14

WIND-TUNNEL INVESTIGATION OF A RAM-JET MISSILE MODEL HAVING A WING AND CANARD SURFACES OF DELTA PLAN FORM WITH 70° SWEPT LEADING EDGES. FORCE AND MOMENT CHARACTERISTICS OF VARIOUS COMBINATIONS OF COMPONENTS AT A MACH NUMBER OF 1.6. Clyde V. Hamilton, Cornelius Driver, and John R. Sevier, Jr. March 1953. 48p. diagrs., photo., tabs. (NACA RM L53A14)

A force investigation of a canard missile configuration having a wing and canard surfaces of delta plan form with 70° swept leading edges and various combinations of its components has been conducted in the Langley 4- by 4-foot supersonic pressure tunnel at a Mach number of 1.61 and a Reynolds number of 3.83×10^6 based on wing mean aerodynamic chord. Longitudinal- and lateral-force characteristics are presented for an angle-of-attack range from -4° to 14° and an angle-of-sideslip range from -4° to 10°.

NACA RM L54A20

AERODYNAMIC CHARACTERISTICS AT TRANSONIC AND SUPERSONIC SPEEDS OF A ROCKET-PROPELLED AIRPLANE CONFIGURATION HAVING A 52.5° DELTA WING AND A LOW, SWEPT HORIZONTAL TAIL. Alan B. Kehlet. March 1954. 31p. diagrs., photos. (NACA RM L54A20)

A flight investigation was conducted on a rocket-propelled airplane configuration having a 52.5° delta wing with an aspect ratio of 3.08 and NACA 65A003 airfoil sections in the streamwise direction. The configuration had a swept empennage with a horizontal tail of 45° quarter-chord-line sweep mounted in a low position. Characteristics of trim, drag, damping, and longitudinal and directional stability at low lift were presented over a Mach number range from 0.79 to 1.83.

NACA RM L54A21

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE EFFECTS OF WING-MOUNTED EXTERNAL STORES ON THE LOADING AND AERODYNAMIC CHARACTERISTICS IN PITCH OF A 45° SWEPTBACK WING COMBINED WITH A FUSELAGE. H. Norman Silvers, Thomas J. King, Jr., and William J. Alford, Jr. March 1954. 36p. diagrs., tabs. (NACA RM L54A21)

Ogive-cylinder external stores of fineness ratio 9.34 were tested in the Langley high-speed 7- by 10-foot tunnel to determine the effect of tip-mounted, inboard, and combined inboard and tip-mounted arrangements on the loading characteristics of a 45° sweptback wing of aspect ratio 4.0 and taper ratio 0.60 that was combined with a fuselage. Overall force and moment characteristics of the model with the various store arrangements are also presented.

NACA RM L54L31b

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF SWEEPBACK AND THICKNESS RATIO ON THE WING LOADS OF A WING-BODY COMBINATION OF ASPECT RATIO 4 AND TAPER RATIO 0.6. Robert J. Platt, Jr., and Joseph D. Brooks. April 1955. 44p. diagrs., photos., tab. (NACA RM L54L31b)

Sweepback angles of 0°, 35°, and 45° were investigated in the Langley 8-foot transonic pressure tunnel for a wing with an aspect ratio of 4, taper ratio of 0.6, and NACA 65A006 airfoil sections. An additional unswept wing with NACA 65A004 airfoil sections was tested to provide information on thickness effects. The tests covered a Mach number range from 0.6 to 1.2 at a Reynolds number of about 2×10^6.

NACA RM L55A05a

INVESTIGATION AT TRANSONIC SPEEDS OF AERODYNAMIC CHARACTERISTICS OF A SEMICIRCULAR AIR INLET IN THE ROOT OF A 45° SWEPTBACK WING. Charles D. Trescot, Jr., and Arvid L. Keith, Jr. March 1955. 30p. diagrs., photos., tab. (NACA RM L55A05a)

An investigation has been made in the Langley transonic blowdown tunnel at Mach numbers from 0.63 to 1.41 to study internal and external aerodynamic characteristics of a sweptback semicircular air inlet installed in the root of a 45° sweptback wing-body combination through a range of mass-flow ratio and angle of attack from 0.36 to 0.91 and 0.4° to 8.5°, respectively. Total-pressure ratio at the assumed engine-face station varied from 0.97 at subsonic speeds to 0.84 at the maximum test speed for a mass-flow ratio of 0.80. Addition of the inlet increased the transonic drag rise of the basic wing-body combination by 0.004 at low angles of attack.

NACA RM L55A07a

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE LONGITUDINAL FORCE AND MOMENT CHARACTERISTICS OF TWO DELTA WINGS AND ONE CLIPPED-TIP DELTA WING OF 4 PERCENT THICKNESS ON A SLENDER BODY. William E. Palmer and Dale L. Burrows. April 1955. 31p. diagrs., photo. (NACA RM L55A07a)

A transonic wind-tunnel investigation has been made at angles of attack as high as 20° and a Reynolds number of about 5 x 10^6 of an aspect-ratio-4 delta wing, an aspect-ratio-3 delta wing, and an aspect-ratio-3 clipped delta wing, all with NACA 65A004 airfoil sections streamwise. Results showed that reduction of the aspect ratio by clipping the tips had less adverse effect on the aerodynamic characteristics than reduction of the aspect ratio by increasing the leading-edge sweep angle; so, in general, the aspect-ratio-3 clipped delta wing had better characteristics than the aspect-ratio-3 delta wing.

NACA RM L55A14

FLUTTER EXPERIENCES WITH THIN POINTED-TIP WINGS DURING FLIGHT TESTS OF ROCKET-PROPELLED MODELS AT MACH NUMBERS FROM 0.8 TO 1.95. Harvey A. Wallskog. April 1955. 32p. diagrs., photos., tabs. (NACA RM L55A14)

Flutter data were obtained from five thin delta, diamond, and arrow wings when tested in free flight over the Mach number range from 0.8 to 1.95 as part of a general zero-lift drag investigation. The results show that pointed-tip wings of high overall static strength may possess poor flutter characteristics depending to some extent on the distribution of material (in laminated wood-metal structures). Although insufficient data were available to establish a flutter boundary for all pointed-tip wings, it is believed that these data may be useful to a designer in comparing his design to others which did or did not experience flutter.

NACA RM L55J28

ANALYSIS OF A FLIGHT INVESTIGATION AT SUPERSONIC SPEEDS OF A SIMPLE HOMING SYSTEM. Robert A. Gardiner, Clarence L. Gillis, and G. B. Graves, Jr. January 1956. 55p. diagrs., photos. (NACA RM L55J28)

A flight investigation of a simple homing device utilizing unique guidance principles has been conducted. From the telemetered data and the photographic records of the trajectory of a supersonic test missile homing on a parachute flare, it is concluded that the principle of guidance and control exemplified by the simple homing system is fundamentally sound. As a result of analog studies concerned primarily with the ratio of rolling frequency to airframe frequency, it is concluded that considerable system improvement may be obtained from further research.

NACA RM L56A04

ANALYSIS OF AN AUTOMATIC CONTROL TO PREVENT ROLLING DIVERGENCE. William H. Phillips. April 1956. 31p. diagrs., tab. (NACA RM L56A04)

Results are presented of an analog computer investigation of an automatic control intended to prevent rolling divergence by offsetting the roll coupling terms in the equations of motion. The control is shown to be effective in the cases studied. A gyroscopic instrument for sensing the product of two angular velocities about perpendicular axes, a necessary input to the proposed control, is described.

NACA RM L56A06a

AN EXPERIMENTAL STUDY AT HIGH SUBSONIC SPEEDS OF SEVERAL TAIL CONFIGURATIONS ON A MODEL WITH AN UNSWEPT WING. William C. Sleeman, Jr. April 1956. 67p. diagrs., photos. (NACA RM L56A06a)

An investigation was conducted in the Langley high-speed 7- by 10-foot tunnel of the static longitudinal and lateral stability characteristics of a model having several different tail arrangements. A systematic series of Y-tails, including a V-tail, was tested and comparative results obtained for a +-tail and X-tail arrangement. The test results were compared with a more conventional T-tail. All of the tails were unswept and of rectangular plan form. The model wing was of aspect ratio 3, taper ratio 0.5, and had an unswept half-chord line. The test Mach number range extended from 0.60 to 0.94 and the angle-of-attack range extended from -4° to 22° at the lowest test Mach number.

NACA RM L56A17

LATERAL STABILITY CHARACTERISTICS BETWEEN MACH NUMBERS OF 0.80 AND 1.57 AND SIMULATION OF COUPLED MOTION AT MACH NUMBER 1.30 OF A ROCKET-PROPELLED MODEL OF AN AIRPLANE CONFIGURATION HAVING THIN HIGHLY TAPERED 45° SWEPTBACK SURFACES. Charles T. D'Aiutolo and Allen B. Henning. April 1956. 41p. diagrs., photos., tabs. (NACA RM L56A17)

A rocket-propelled model of an airplane configuration having thin, highly tapered, 45° sweptback surfaces was tested in the Mach number range of 0.80 to 1.57 to obtain the lateral stability characteristics of the configuration. The model experienced a violent lateral-longitudinal motion at a Mach number of 1.3, and an approximate simulation of this motion on an analog computer indicated possible values of the stability derivatives of the model while undergoing this maneuver. An analysis of the Dutch roll oscillation was performed by the time-vector method and the single-degree-of-freedom method to determine the lateral stability derivatives C_{Y_β}, C_{n_β}, C_{l_β}, C_{l_p}, and $\left(C_{n_r} - C_{n_\beta}\right)$.

NACA RM L56A24

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF SOME EFFECTS OF SIDESLIP ON THE AERODYNAMIC LOADS ON FINNED AND UNFINNED BODIES MOUNTED FROM THE WING OF A SWEPT-WING—FUSELAGE MODEL. Thomas J. King, Jr. April 1956. 50p. diagrs., tabs. (NACA RM L56A24)

Finned and unfinned ogive-cylinder bodies of fineness ratio 9.34 were tested on a swept-wing—fuselage model in sideslip in the Langley high-speed 7- by 10-foot tunnel. For one arrangement, one instrumented body was mounted directly to the left wing tip; for a second arrangement, two bodies (one instrumented), symmetrically located about the plane of symmetry, were mounted to pylons in an inboard location. Five-component force and moment measurements (no axial force) were made of the left-wing bodies in the presence of the model over a Mach number range of 0.50 to 0.94.

NACA RM L56A25a

EFFECT OF FUSELAGE AIR BRAKES ON THE LONGITUDINAL STABILITY CHARACTERISTICS OF A SWEPT-WING FIGHTER MODEL AT TRANSONIC SPEEDS. Donald D. Arabian. April 1956. 22p. diagrs., photos. (NACA RM L56A25a)

An investigation was conducted on a 40° swept-wing fighter model at transonic speeds to determine the effect of extending a fuselage-type air brake located near the wing. Force and moment data and wing pressures were measured and are presented for a range of Mach numbers and angles of attack.

NACA RM L56A26a

AERODYNAMIC DAMPING AT MACH NUMBERS OF 1.3 AND 1.6 OF A CONTROL SURFACE ON A TWO-DIMENSIONAL WING BY THE FREE-OSCILLATION METHOD. W. J. Tuovila and Robert W. Hess. May 1956. 21p. diagrs., tabs. (NACA RM L56A26a)

Tests have been made at two supersonic speeds to obtain experimentally the aerodynamic damping characteristics of a control surface on a two-dimensional wing. The test results are compared with results calculated by two- and three-dimensional oscillating air-force theories. At a Mach number of 1.6, both theories are in fairly good agreement with the experimental results. At a Mach number of 1.3, both theories predict negative (unstable) damping, whereas the tests indicate that the damping is slightly positive (stable). The in-phase or aerodynamic stiffness coefficients predicted by both theories are slightly higher than the experimentally determined coefficients.

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF A HEATED PROPULSIVE JET ON THE PRESSURE DISTRIBUTION ALONG A FUSELAGE OVERHANG. Elden S. Cornette and Donald H. Ward. April 1956. 42p. diagrs., photos., tab. (NACA RM L56A27)

Pressure-distribution data were obtained on fuselage surfaces which extended downstream of a jet exit and were subject to the influence of a heated propulsive jet. Three fuselage-overhang configurations were investigated at free-stream Mach numbers from 0.80 to 1.10 while jet pressure ratio was varied from 1 to 11 at jet-exit temperatures of cold, 800° F, and 1200° F.

NACA RM L56A31

AN EVALUATION OF AN AEROMECHANICAL METHOD OF MINIMIZING SERVO-MISSILE TRANSFER-FUNCTION VARIATIONS WITH FLIGHT CONDITION. Martin L. Nason. April 1956. 41p. diagrs., tabs. (NACA RM L56A31)

An investigation has been conducted to evaluate the properties of a control-surface actuator and missile combination considered from the standpoint of the minimization of the effects of Mach number and altitude. A torque servo, employing judicious amounts of control-surface-position feedback, was found to have exceptionally favorable static and dynamic operating characteristics as compared with a conventional position servo-actuated missile. The control-surface-position feedback loop exhibited a strong stabilizing influence on the damping of the airframe mode and careful adjustment of the torque servo and position feedback gain constants considerably reduced the percentage Mach number and altitude variation of the available missile turning rate.

NACA RM L56B21

WIND-TUNNEL INVESTIGATION OF A RAM-JET MISSILE MODEL HAVING A WING AND CANARD SURFACES OF DELTA PLAN FORM WITH 70° SWEPT LEADING EDGES. FORCE AND MOMENT CHARACTERISTICS AT COMBINED ANGLES OF PITCH AND SIDESLIP FOR MACH NUMBER 2.01. Cornelius Driver and Clyde V. Hamilton. April 1956. 67p. diagrs., photo., tabs. (NACA RM L56B21)

An investigation has been conducted in the Langley 4- by 4-foot supersonic pressure tunnel to determine the static stability and control characteristics of a ram-jet canard missile at a Mach number of 2.01. The complete model and various combinations of its components were tested through an incidence angle range from -2° to about 26° at various roll angles from 0° to -90°. A resolution of these results provides the aerodynamic characteristics for the missile at angles of attack up to about 26° at zero sideslip or at combinations of angle of attack and angle of sideslip up to a maximum of about 16° for each.

This is authority for those possessing copies of the following research report to declassify it from Secret. Effective date of declassification January 20, 1958.

SPECIAL NOTICE

Holders of NACA Technical Note 4201 by William E. Stoney, Jr., are requested to delete from page 13 the word "CONFIDENTIAL," which was printed in error.

SPECIAL NOTICE

1. If there is enough sales potential, AGARD will reprint the Flight Test Manual in a commercial edition. Please write NACA if you want to be counted as a prospective purchaser. If reprinted, the Manual will probably be available next fall; we don't know the price.

2. The commercial source of AGARDograph 20, History of German Guided Missiles Development, was incorrectly announced in NACA Research Abstracts 124 as being Interscience Publishers, Inc. Purchase orders for AGARDograph 20 should properly be addressed to

Wissenschaftliche Gesellschaft fur Luftfahrt e.V. (WGL)
Postfach 674
Braunschweig, Germany.

The price is $7.50.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1301

LINEARIZED LIFTING-SURFACE AND LIFTING-LINE EVALUATIONS OF SIDEWASH BEHIND ROLLING TRIANGULAR WINGS AT SUPERSONIC SPEEDS. Percy J. Bobbitt. 1957. ii, 19p. diagrs., photo. (NACA Rept. 1301. Supersedes TN 3609)

The sidewash in the vertical plane of symmetry behind steady-rolling triangular wings traveling at supersonic speeds has been derived by use of both linearized lifting-surface and lifting-line methods. The lifting-surface results are limited by the condition that the wing leading edges must be subsonic. Variations of the sidewash with vertical and longitudinal distances are presented in graphical form for a number of combinations of Mach number and leading-edge sweep. Sidewash computed by the lifting-line method showed good agreement with lifting-surface results except close behind the trailing edge when the leading edge approached the sonic condition. An illustrative calculation has been made of the force induced by the sidewash behind a triangular wing on a vertical tail located in various longitudinal positions. The approximate lifting-line expression may be used to compute the sidewash behind rolling wings of arbitrary plan form and span loading.

NACA Rept. 1308

INVESTIGATION OF THE COMPRESSIVE STRENGTH AND CREEP LIFETIME OF 2024-T3 ALUMINUM-ALLOY PLATES AT ELEVATED TEMPERATURES. Eldon E. Mathauser and William D. Deveikis. 1957. ii, 14p. diagrs., photos., tabs. (NACA Rept. 1308. Supersedes TN 3552)

The results of elevated-temperature compressive-strength and creep tests of 2024-T3 (formerly 24S-T3) aluminum-alloy plates supported in V-grooves are presented. The strength-test results indicate that a relation previously developed for predicting plate compressive strength at room temperature is satisfactory for determining elevated-temperature strength. Creep-lifetime results are presented for the plates in the form of master creep-lifetime curves by using a time-temperature parameter that is convenient for summarizing tensile creep-rupture data. The use of isochronous stress-strain curves obtained from plate-creep curves for predicting plate-creep failure stresses is investigated.

NACA Rept. 1320

AN EVALUATION OF FOUR EXPERIMENTAL METHODS FOR MEASURING MEAN PROPERTIES OF A SUPERSONIC TURBULENT BOUNDARY LAYER. George J. Nothwang. 1957. ii, 11p. diagrs., photos. (NACA Rept. 1320. Supersedes TN 3721)

Surveys were made through the flat plate turbulent boundary layer at a Mach number of 3 using a pitot probe, an X-ray densitometer, and cold-wire and

CURRENT NACA RESEARCH REPORTS

hot-wire probes. The first three methods indicated consistent mean values of pitot pressure, density, and total temperature; the hot-wire probe, however, indicated larger values of mean mass flow. The assumption of constant total temperature through the boundary layer yielded negligible errors in velocity distribution, and displacement and momentum thicknesses.

NACA RM E57K19a

CORRELATION OF TURBULENT HEAT TRANSFER IN A TUBE FOR THE DISSOCIATING SYSTEM $N_2O_4 \rightleftarrows 2NO_2$. Richard S. Brokaw. March 1958. 17p. diagrs., tabs. (NACA RM E57K19a)

Experimental data are in accord with the usual Nusselt-Prandtl-Reynolds number correlation for this type of convective heat transfer. Calculated equilibrium thermal conductivities and kinematic viscosities were used. An approximate method using frozen gas properties gave somewhat poorer results, but should be useful for complex systems or systems in which chemical equilibrium is not attained. In nonequilibrium systems, the enthalpy of the gas in the free stream and at the wall must be known.

NACA RM E57K22

THEORETICAL ROCKET PERFORMANCE OF JP-4 FUEL WITH SEVERAL FLUORINE-OXYGEN MIXTURES ASSUMING EQUILIBRIUM COMPOSITION. Sanford Gordon. February 1958. 69p. diagrs., tabs. (NACA RM E57K22)

Data were calculated for a chamber pressure of 600 pounds per square inch absolute, fluorine in oxidant from 0 to 100 percent, pressure ratios of 1 to 1500, and a range of equivalence ratios. Parameters included are specific impulse, combustion and exit temperatures, molecular weight, characteristic velocity, coefficient of thrust, area ratio, specific heat, isentropic exponent, viscosity, thermal conductivity, and equilibrium gas compositions. Maximum specific impulse for expansion to 1 atmosphere is 325.7 pound-seconds per pound at 70.37 percent fluorine in oxidant.

NACA RM E57K22a

ELEVATED-TEMPERATURE COMBINED STRESS-RUPTURE PLUS FATIGUE STRENGTH OF WASPALOY HAVING DIFFERENT AGING TREATMENTS AND/OR MOLYBDENUM CONTENTS. C. A. Hoffman and M. B. Hornak. February 1958. 21p. diagrs., photos., tabs. (NACA RM E57K22a)

Waspaloy was studied (at 1500° F) to determine if stress-rupture ductilities and notch sensitivities associated with given aging treatments and/or molybdenum contents could be correlated with respective combined stress-rupture plus fatigue strengths. A possible relation between stress-rupture ductility and combined stress-rupture plus fatigue strength was indicated. No clear relation was found between notch-rupture strength and combined stress-rupture plus fatigue strength. If heat treatment and/or composition alone are considered, results indicate that double aging could improve combined stress strength and that double aging plus increased molybdenum content could cause a further increase in combined stress strength of Waspaloy.

NACA RM L57L05

LIMITED INVESTIGATION OF NOISE SUPPRESSION BY INJECTION OF WATER INTO EXHAUST OF AFTERBURNING JET ENGINE. Max C. Kurbjun. February 1958. 15p. diagrs., photo. (NACA RM L57L05)

A preliminary investigation of the effect of injection of up to 880 gallons of water per minute on the noise production of an afterburning jet engine producing 8,000 pounds of thrust showed a reduction of 2 to 6 decibels in overall sound-pressure level in the direction of maximum noise radiation. It was further noted that the reduction in overall sound pressure was achieved by significant reductions (up to 10 decibels) in the range of frequencies below 800 cps, a region where the attenuation due to atmospheric losses is negligible.

NACA RM L57L12

SUMMARY OF LOCATIONS, EXTENTS, AND INTENSITIES OF TURBULENT AREAS ENCOUNTERED DURING FLIGHT INVESTIGATIONS OF THE JET STREAM FROM JANUARY 7, 1957 TO APRIL 28, 1957. Martin R. Copp. March 1958. 8p. tab. (NACA RM L57L12)

A summary of the locations, extents, and intensities of turbulent areas encountered during a flight investigation of the jet stream is presented. The data were obtained from NACA time-history records.

NACA RM L58A17

EFFECT OF DISTRIBUTED GRANULAR-TYPE ROUGHNESS ON BOUNDARY-LAYER TRANSITION AT SUPERSONIC SPEEDS WITH AND WITHOUT SURFACE COOLING. Albert L. Braslow. March 1958. 22p. diagrs., photos. (NACA RM L58A17)

An investigation at a Mach number of 2.01 and 1.61 in the Langley 4- by 4-foot supersonic pressure tunnel showed that for a distributed granular-type surface roughness, transition could be correlated at supersonic speeds on the basis of a critical local roughness Reynolds number similar to that previously developed for use at subsonic speeds. Surface cooling did not increase the value of the critical roughness Reynolds number to any important extent, and, therefore, promoted transition due to existing three-dimensional surface roughness because of the adverse effect of cooling on the actual roughness Reynolds number.

CURRENT NACA RESEARCH REPORTS

NACA TM 1404

INVESTIGATION OF APERIODIC TIME PROCESSES WITH AUTOCORRELATION AND FOURIER ANALYSIS. (Untersuchung unperiodischer Zeitvorgänge mit der Autokorrelations und der Fourieranalyse.) Marie Luise Exner. March 1958. 44p. diagrs., photos., tabs. (NACA TM 1404. Translation from Acustica, v. 4, no. 3, 1954, p. 365-379)

Autocorrelation and frequency analyses of a series of aperiodic time events, in particular, filtered noises and sibilant sounds, were made. The position and band width of the frequency ranges are best obtained from the frequency analysis, but the energies contained in the several bands are most easily obtained from the autocorrelation function. The mean number of zero crossings of the time function was determined from the curvature of the latter function in the vicinity of the zero crossing, and also with the aid of a decimal counter. The second method was found to be more exact.

NACA TM 1413

IMPACT ON A COMPRESSIBLE FLUID. (Udar o szhimaemuiu zhidkost.) I. T. Egorov. February 1958. 12p. diagrs. (NACA TM 1413. Translation from Prikladnaia Matematika i Mekhanika, v. 20, no. 1, 1956, p. 67-72)

Theoretical solution is made of vertical hydrodynamic impact of a flat rigid body on the surface of a nonviscous compressible fluid. The solution is based on potential motion of the fluid. Rise of the fluid near the body is considered to be negligible. The equations permit calculation of histories of impact force and motion. Histories of kinetic energy and momentum for impacts at 5 m sec^{-1} on water, alcohol, and pentane are calculated.

NACA TM 1432

EVAPORATION, HEAT TRANSFER, AND VELOCITY DISTRIBUTION IN TWO-DIMENSIONAL AND ROTATIONALLY SYMMETRICAL LAMINAR BOUNDARY-LAYER FLOW. (Verdunstung, Wärmeübergang und Geschwindigkeitsverteilung bei zweidimensionaler und rotationssymmetrischer laminarer Grenzschichtströmung.) Nils Frössling. February 1958. 37p. tabs. (NACA TM 1432. Translation from Lunds Universitets Arsskrift, v. 36, no. 4. Kungl. Fysiografiska Sallskapets Handlingar, v. 51, no. 4, 1940)

A theoretical investigation is made of the boundary-layer flow over two-dimensional bodies and over bodies of revolution. The evaporation, the heat transfer, and the boundary-layer velocity profiles are calculated by power-series developments with respect to the distance along the surface. The coefficient functions that occur in the series developments were chosen so that they are valid for all pressure distributions; some of these coefficient functions were calculated numerically. Methods for the determination of the errors caused by breaking off the series are briefly treated. Methods of proceeding further along the surface are discussed. It is shown, for large Prandtl numbers, that the Nusselt number is exactly proportional to the cube root of the Prandtl number. Finally, approximate methods of calculation are discussed.

NACA TN 4036

CREEP OF ALUMINUM-COPPER ALLOYS DURING AGE HARDENING. E. E. Underwood, L. L. Marsh, and G. K. Manning, Battelle Memorial Institute. February 1958. 73p. diagrs., photos., tabs. (NACA TN 4036)

The interrelation of aging during creep and of creep during aging has been studied in polycrystalline aluminum alloys containing 1 to 4 percent copper. Experimental procedures included interrupted creep tests, tensile tests of crept specimens, quantitative metallographic determination of the percent precipitation during creep, hardness measurements on unstressed and stressed aged alloys, X-ray studies of deformation in the crystalline lattice, and microscopic examination of the surface-deformation markings.

NACA TN 4133

BOUNDARY-LAYER DISPLACEMENT EFFECTS IN AIR AT MACH NUMBERS OF 6.8 AND 9.6. Mitchel H. Bertram. February 1958. 61p. diagrs., photos. (NACA TN 4133)

Measurements are presented for boundary-layer-induced pressure gradients on a flat plate in air at a Mach number of 9.6 and for the drag of thin wings at a Mach number of 6.8 and zero angle of attack. The investigation was conducted in the Langley 11-inch hypersonic tunnel, and the pressure measurements at a Mach number of 9.6 were made in the presence of substantial heat transfer from the boundary layer to the wall.

NACA TN 4136

THEORETICAL INVESTIGATION OF SUBSONIC OSCILLATORY BLADE-ROW AERODYNAMICS. Frank Lane and Manfred Friedman, New York University. February 1958. 64p. diagrs., tabs. (NACA TN 4136)

A method is presented for calculating the aerodynamic lifts and moments experienced by a cascade or two-dimensional approximation to a compressor or turbine blade row in subsonic flow under harmonic oscillation. Arbitrary stagger and interblade phase-lag angles are permitted. The most significant features of the method stem from the utilization of Fourier transforms of blade pressure-jump functions.

CURRENT NACA RESEARCH REPORTS

NACA TN 4139

WALL PRESSURE FLUCTUATIONS IN A TURBULENT BOUNDARY LAYER. William W. Willmarth, California Institute of Technology. March 1958. 39p. diagrs., photo. (NACA TN 4139)

A low-noise- and low-turbulence-level wind tunnel and a flush-mounted barium titanate transducer have been used to measure the wall pressure fluctuations in a turbulent boundary layer. It was found that the spectrum of the wall pressure fluctuations extended to 50 kilocycles and that the root-mean-square wall pressure was a constant part of the free-stream dynamic pressure for $0.2 < M < 0.8$ and $1.5 < Re < 20 \times 10^6$. A few typical spectra are given for different values of Reynolds number and Mach number.

NACA TN 4145

AN ANALYSIS OF THE OPTIMIZATION OF A BEAM RIDER MISSILE SYSTEM. Marvin Shinbrot and Grace C. Carpenter. March 1958. 34p. diagrs. (NACA TN 4145)

A transfer function is derived for a beam rider missile guidance system which is optimum when the target moves in a nonstationary way. The effects of acceleration limiting are considered and a discussion of the miss as a function of the various parameters which determine it is included. A form of design chart is presented which allows the immediate determination of the optimum under any set of target-missile conditions.

NACA TN 4147

MEASURED AND PREDICTED DYNAMIC RESPONSE CHARACTERISTICS OF A FLEXIBLE AIRPLANE TO ELEVATOR CONTROL OVER A FREQUENCY RANGE INCLUDING THREE STRUCTURAL MODES. Henry A. Cole, Jr., and Euclid C. Holleman. February 1958. 81p. diagrs., photo., tabs. (NACA TN 4147)

The dynamic response of selected points on a flexible airplane to elevator motions is presented over the operating Mach number range at altitudes from 15,000 to 35,000 feet. Comparisons are made between measured responses over various frequency bands and predicted responses based on equations with three structural degrees of freedom.

NACA TN 4149

AN ANALYSIS OF THE TURBULENT BOUNDARY-LAYER CHARACTERISTICS ON A FLAT PLATE WITH DISTRIBUTED LIGHT-GAS INJECTION. Morris W. Rubesin and Constantine C. Pappas. February 1958. 43p. diagrs. (NACA TN 4149)

An exploratory analysis has been developed for the case of distributed injection of a foreign gas into a turbulent boundary layer in air on a flat plate. The work is divided into three parts: a derivation of the basic turbulent boundary-layer equations for a binary gas system; a derivation of modified Reynolds analogies between momentum, mass, and heat transfer for a binary gas system; and an evaluation of the effect of foreign gas injection on the skin friction and heat transfer of a nearly isothermal boundary layer using mixing length theory. Numerical results are given for the injection of the light gases, hydrogen, and helium.

NACA TN 4151

CORRELATIONS AMONG ICE MEASUREMENTS, IMPINGEMENT RATES, ICING CONDITIONS, AND DRAG COEFFICIENTS FOR UNSWEPT NACA 65A004 AIRFOIL. Vernon H. Gray. February 1958. 45p. diagrs., photos., tabs. (NACA TN 4151)

An empirical relation is derived by which changes in section drag coefficients due to ice on an NACA 65A004 airfoil are calculable from known icing and operating conditions. The correlation is obtained by use of measured ice heights and ice angles. Initial ice weights are in agreement with droplet impingement data; in glaze conditions, ice weights increase at progressively greater rates with time.

NACA TN 4153

EFFECT OF WALL COOLING ON INLET PARAMETERS OF A SCOOP OPERATING IN A TURBULENT BOUNDARY LAYER ON A FLAT OR CONICAL SURFACE FOR MACH NUMBERS 2 TO 10. Andrew Beke. March 1958. 21p. diagrs., tabs. (NACA TN 4153)

Mass-flow, momentum, total-temperature, and total-pressure recovery ratios were calculated for a scoop inlet having a height equal to the boundary-layer thickness. Wall cooling on a flat or conical surface increases the inlet mass-flow and momentum ratios up to 50 percent, and reduces the total-temperature ratio of the boundary-layer mass flow by about 6 percent with small increases in total-pressure recovery.

CURRENT NACA RESEARCH REPORTS

NACA TN 4155

AERODYNAMIC EFFECTS CAUSED BY ICING OF AN UNSWEPT NACA 65A004 AIRFOIL. Vernon H. Gray and Uwe H. von Glahn. February 1958. 47p. diagrs., photos., tabs. (NACA TN 4155)

At angles of attack less than 4° both rime and glaze-ice formations increased drag, reduced lift, and reduced diving moments. At angles of attack greater than 4°, drag coefficients increased with glaze-ice formations and decreased with rime ice; lift coefficients generally increased with glaze ice and were variably affected by rime ice; pitching-moment changes were rather erratic and depended on the ice shape. When the airfoil was iced at high angles of attack and rotated to lower angles, large negative pitching moments were obtained. Ice formations on the airfoil had no significant effects on control-surface hinge moments.

NACA TN 4158

ACCELERATIONS IN TRANSPORT-AIRPLANE CRASHES. G. Merritt Preston and Gerard J. Pesman. February 1958. 76p. diagrs., photos., tab. (NACA TN 4158)

Full-scale aircraft crashes were made with low-wing pressurized and high- and low-wing unpressurized transport airplanes to determine the crash loads that result from a variety of crash events. The effects of the crash circumstances and the airplane configuration on the magnitude of the crash loads are indicated.

NACA TN 4161

EFFECT OF LUBRICANT BASE STOCK ON ROLLING-CONTACT FATIGUE LIFE. Thomas L. Carter. February 1958. 28p. diagrs., tab. (NACA TN 4161)

Five different base-stock fluids, a methyl silicone, a mineral oil, a glycol, a sebacate, and an adipate, were tested as lubricants in the rolling-contact fatigue spin rig using groups of air-melt M-1 tool-steel balls at 100° F. Other test conditions such as lubricant viscosity, at test temperature, and ball loading were held constant. Differences were observed in the ball fatigue lives produced with these lubricants. Lubricants whose viscosities were increased the most by pressure produced the longest fatigue lives. No differences were observed in chemical or metallurgical effects or in failure type.

NACA TN 4180

INVESTIGATION OF SPOILERS AT A MACH NUMBER OF 1.93 TO DETERMINE THE EFFECTS OF HEIGHT AND CHORDWISE LOCATION ON THE SECTION AERODYNAMIC CHARACTERISTICS OF A TWO-DIMENSIONAL WING. James N. Mueller. February 1958. 52p. diagrs., photos. (NACA TN 4180. Supersedes RM L52L31)

The results of a pressure-distribution investigation of a 6-percent-thick symmetrical wing with spoilers are presented for a Reynolds number of approximately 1×10^6. The values of section normal force and pitching moment are presented as a function of angle of attack, spoiler height, and spoiler chordwise location. Some effects of spoiler height on spoiler pressure drag are shown for several angles of attack and two chordwise spoiler locations.

NACA TN 4183

INVESTIGATION OF EFFECTS OF DISTRIBUTED SURFACE ROUGHNESS ON A TURBULENT BOUNDARY LAYER OVER A BODY OF REVOLUTION AT A MACH NUMBER OF 2.01. John R. Sevier, Jr., and K. R. Czarnecki. February 1958. 31p. diagrs., photos. (NACA TN 4183)

An investigation of three ogive-cylinders over a surface-roughness range from 23 to 480 microinches root mean square was made at zero angle of attack for a Reynolds number range based on body length from 4×10^6 to 30×10^6. The drag and base pressure were measured for conditions of natural and fixed transition. The results are compared with those of tests of the same models at a Mach number of 1.61, and the comparison indicates that increasing the Mach number from 1.61 to 2.01 results in a 40-percent increase in allowable roughness height for the turbulent boundary layer. This increase is in good agreement with that predicted on the basis of a constant ratio of allowable roughness height to laminar-sublayer thickness or to a constant value of the Reynolds number based on allowable roughness height, shearing-stress velocity, and local conditions at the surface.

NACA TN 4188

CHARTS RELATING THE COMPRESSIVE AND SHEAR BUCKLING STRESSES OF LONGITUDINALLY SUPPORTED PLATES TO THE EFFECTIVE DEFLECTIONAL STIFFNESS OF THE SUPPORTS. Aldie E. Johnson, Jr. February 1958. 42p. diagrs., tab. (NACA TN 4188)

A stability analysis is made of long flat rectangular plates subjected to both shear and compressive loads. The edges of the plates are taken to be simply supported and the plates are supported along one or two intermediate longitudinal lines by lines of deflectional springs (elastic line supports). The results of the analysis are presented in the form of charts that are useful in the determination of the buckling load of plates stiffened by stringers or webs.

CURRENT NACA RESEARCH REPORTS

NACA TN 4194

COMPARISON OF HYDRODYNAMIC-IMPACT ACCELERATION AND RESPONSE FOR SYSTEMS WITH SINGLE AND WITH MULTIPLE ELASTIC MODES. Robert W. Miller. February 1958. 30p. diagrs., photos., tabs. (NACA TN 4194)

Hydrodynamic-impact tests were made on a multimode elastic model consisting of a rigid prismatic float and a flexible wing. Comparisons of multimode results with theoretical and experimental results for a single-mode system having the same mass ratio indicate that the applied accelerations are in agreement with those obtained by the method of NACA Report 1074 and that the higher modes present had no significant effect on the applied accelerations.

NACA TN 4196

A METHOD FOR THE CALCULATION OF THE LATERAL RESPONSE OF AIRPLANES TO RANDOM TURBULENCE. John M. Eggleston and William H. Phillips. February 1958. 34p. diagrs., tab. (NACA TN 4196)

In this method, the gust velocities are represented as rolling gusts, yawing gusts, and side gusts. Random distributions of gust velocities across the span are taken into account in defining the rolling and yawing gusts. Complex stability derivatives are used to account for the random distribution of side gusts along the fuselage and vertical tail and the lag effects in gust penetration. A sample calculation procedure is presented for obtaining the response of the airplane in each degree of freedom.

NACA TN 4197

SUMMARY OF FLUTTER EXPERIENCES AS A GUIDE TO THE PRELIMINARY DESIGN OF LIFTING SURFACES ON MISSILES. Dennis J. Martin. February 1958. 21p. diagrs. (NACA TN 4197. Supersedes RM L51J30)

Presented is a limited review of some experiences in flight testing of missiles and of wing flutter investigations that may be of interest in missile design. Several types of flutter of concern in missile studies are briefly described. Crude criteria are presented for two of the most common types of flutter to permit a rapid estimate to be made of the probability of the occurrence of flutter. Many of the details of the flutter problem have been omitted, and only the broader elements have been retained so as to give the designer an overall view of the subject.

NACA TN 4200

EFFECTIVENESS OF BOUNDARY-LAYER CONTROL, OBTAINED BY BLOWING OVER A PLAIN REAR FLAP IN COMBINATION WITH A FORWARD SLOTTED FLAP, IN DEFLECTING A SLIPSTREAM DOWNWARD FOR VERTICAL TAKE-OFF. Kenneth P. Spreemann. February 1958. 32p. diagrs., photo. (NACA TN 4200)

The wing employed in this investigation had a 67-percent-chord slotted flap in combination with a 33-percent-chord plain rear flap equipped with a full-span blowing nozzle. The tests were conducted in a static-thrust facility at the Langley Aeronautical Laboratory. The investigation indicated that the plain rear flap alone with a low momentum coefficient for boundary-layer control provided larger turning angles than the combined slotted and plain flaps without boundary-layer control.

NACA TN 4202

QUALITATIVE SIMULATOR STUDY OF LONGITUDINAL STICK FORCES AND DISPLACEMENTS DESIRABLE DURING TRACKING. Stanley Faber. February 1958. 23p. diagrs., photo. (NACA TN 4202)

In this study in which an airplane simulator with one degree of freedom (pitch) was used, results were determined for three conditions of airplane dynamics. For an undamped natural frequency of 1/2 cps with a damping ratio of 0.8, low stick-force gradients and stick-displacement gearings were desired. For an undamped natural frequency of 1/2 cps with a damping ratio of 0.18 and for an undamped natural frequency of 1 cps with a damping ratio of 0.11, moderate longitudinal stick forces and displacements were desired.

NACA TN 4203

FLIGHT INVESTIGATION OF EFFECTS OF ATMOSPHERIC TURBULENCE AND MODERATE MANEUVERS ON BENDING AND TORSIONAL MOMENTS ENCOUNTERED BY A HELICOPTER ROTOR BLADE. LeRoy H. Ludi. February 1958. 34p. diagrs., photo., tab. (NACA TN 4203)

Experimental studies of the effects of atmospheric turbulence and moderate maneuvers on the steady and periodic rotor blade moments encountered by a single-rotor helicopter show that atmospheric turbulence and control motions do not produce additional periodic blade moments, except when accompanied by center-of-gravity accelerations, significant to fatigue calculations during the principal part of the flying time. This information permits the use of time spent, as determined by an NACA helicopter VGHN recorder, in conjunction with prototype strain measurements as a basis for that portion of the cumulative fatigue analysis that covers the principal part of the flying time.

CURRENT NACA RESEARCH REPORTS

NACA TN 4204

COMPILATION OF INFORMATION ON THE TRANSONIC ATTACHMENT OF FLOWS AT THE LEADING EDGES OF AIRFOILS. Walter F. Lindsey and Emma Jean Landrum. February 1958. 63p. diagrs., photos., tabs. (NACA TN 4204)

Schlieren photographs have been compiled of the two-dimensional flow at transonic speeds past 37 airfoils. These airfoils have variously shaped profiles, and some are related in thickness and camber. The data for these airfoils were analyzed to provide basic information on the flow changes involved and to determine factors affecting transonic-flow attachment, which is a transition from separated to unseparated flow at the leading edges of two-dimensional airfoils at fixed angles as the subsonic Mach number is increased.

NACA TN 4205

TRANSIENT HEATING EFFECTS ON THE BENDING STRENGTH OF INTEGRAL ALUMINUM-ALLOY BOX BEAMS. Richard A. Pride and John B. Hall, Jr. March 1958. 38p. diagrs., photo., tab. (NACA TN 4205)

Twenty-five square-tube beams were tested to failure under combinations of bending load and symmetrical heating. The results of tests for skin buckling and maximum strength are compared with theoretical calculations. Results for local buckling are calculated from theories combining the effects of appropriate material properties and thermal stress in both elastic- and plastic-stress ranges. A marked reduction in buckling strength was observed as a result of thermal stress. At failure, the results of all tests correlated well with those calculated by a compression maximum-strength theory based solely on appropriate material properties; this correlation indicates that thermal-stress effects which influence local buckling appear alleviated at maximum load.

NACA TN 4209

EXPERIMENTAL THERMAL CONDUCTIVITIES OF THE $N_2O_4 \rightleftarrows 2NO_2$ SYSTEM. Kenneth P. Coffin and Cleveland O'Neal, Jr. February 1958. 22p. diagrs., photo., tab. (NACA TN 4209)

Thermal conductivity was measured by a hot-wire technique at temperatures between 20° and 215° C and pressures from 1/3 to 1 atmosphere; approximate values were obtained at pressures as low as 0.02 atmosphere from 20° to 80° C. Experimental values are in good agreement with values calculated so as to include the effects of dissociation; dissociation produces an order-of-magnitude increase in conductivity.

NACA TN 4210

STABILITY OF PROPANE-AIR FLAMES IN VORTEX FLOW. A. E. Potter, Jr., E. L. Wong, and A. L. Berlad. February 1958. 27p. diagrs., tab. (NACA TN 4210)

The stability limits of propane-air flames in vortex flow were measured. The blowoff velocity was proportional to the 0.73 power of vortex strength, and increased slightly with fuel concentration. The flames were stabilized by a stagnation or near-stagnation region induced by a pressure defect existing at the vortex center. When the vortex strength was made large, the pressure defect at the vortex center drew ambient air into the flame. This caused partial quenching of lean flames. H_2O_2, HCHO, higher aldehydes, CH_3OH, H_2, and CO were found in the combustion products of lean flames in strong vortices.

NACA TN 4211

FRICTION STUDIES OF VARIOUS MATERIALS IN LIQUID NITROGEN. D. W. Wisander, W. F. Hady, and R. L. Johnson. February 1958. 35p. diagrs., photos., tab. (NACA TN 4211)

Friction data were obtained under conditions applicable to positive-displacement pumps (2300 ft/min sliding velocity and 1000-gram load) with a 3/16-inch-radius hemisphere sliding on the flat surface of a rotating disk. Graphite-filled Teflon gave lower friction coefficient (0.15) and wear than other materials, including rolling-contact-bearing metals, mechanical-seal-type carbons, phenolic laminates, and a cermet. Other filled Teflon compositions also gave good results. Phenolic laminates gave relatively high friction (>0.5).

NACA TN 4213

RECOVERY TEMPERATURES AND HEAT TRANSFER NEAR TWO-DIMENSIONAL ROUGHNESS ELEMENTS AT MACH 3.1. Paul F. Brinich. February 1958. 20p. diagrs. (NACA TN 4213)

The effects of single and multiple two-dimensional roughness elements on the temperature distribution, the pressure distribution, and the heat transfer on a hollow cylinder and a cone-cylinder model were determined at Mach 3.1. Abrupt perturbations in surface temperature occurred in the neighborhood of the elements when the boundary layer was turbulent, but were absent when it was laminar. The type of perturbation depended on the element shape, forward-facing wedges giving the lowest temperatures immediately behind the element, and forward-facing steps the highest. For a turbulent boundary layer the heat-transfer rate behind the wedge element was less than that immediately ahead of the element.

CURRENT NACA RESEARCH REPORTS

NACA TN 4214

BOUNDARY-LAYER TRANSITION ON AN OPEN-NOSE CONE AT MACH 3.1. Paul F. Brinich. February 1958. 11p. diagrs. (NACA TN 4214)

Transition locations on an open-nose cone are compared with those on a conventional cone and a hollow cylinder. The transition locations on the sharp open-nose cone are exactly the same as those on the sharp open-nose cylinder. The effects on transition location of blunting the leading edge of the open-nose cone are also quite similar to those observed for the hollow cylinder.

NACA TN 4216

EFFECT OF FIBER ORIENTATION IN RACES AND BALLS UNDER ROLLING-CONTACT FATIGUE CONDITIONS. Thomas L. Carter. February 1958. 37p. diagrs., photos., tabs. (NACA TN 4216)

The rolling-contact fatigue spin rig was used to study the interrelations of fiber orientation and fatigue. In both balls and races, a concentration of fatigue failures was observed in regions with the highest angle of intersection of fiber flow lines with the surface. Also, in races, poorer fatigue life was observed with increasing fiber orientation angle. Each of the ten ball materials studied showed a greater than normal tendency to fail in the polar or end grain areas.

NACA TN 4221

TURBULENT FLOW THROUGH POROUS RESISTANCES SLIGHTLY INCLINED TO THE FLOW DIRECTION. Albert L. Loeffler, Jr., and Morris Perlmutter. February 1958. 30p. diagrs., photos. (NACA TN 4221)

Analytical and experimental studies have been made of the channel flow of air through porous resistances inclined at an angle of $3\text{-}1/2^{\circ}$ to the axis of the channel with the air discharging to the atmosphere. These studies determine the channel wall shape that would yield a uniform discharge through the porous resistance.

NACA TN 4227

DRAG MINIMIZATION FOR WINGS IN SUPERSONIC FLOW, WITH VARIOUS CONSTRAINTS. Max. A. Heaslet and Franklyn B. Fuller. February 1958. 30p. (NACA TN 4227)

Minimization of inviscid fluid drag is studied for wings subject to constraints on lift, pitching moment, base area, or volume. An approximate solution for given lift is obtained. For certain wing classes, analogies between lifting and nonlifting cases are found. Results are given for a family of wings with curved leading edges when lift and a center of pressure at 60-percent chord are specified. Integrals of loading along oblique lines are given. Minimum drag for other plan forms is determined, and, for nonlifting wings, occurrence of unreal shapes is discussed.

NACA TN 4259

TEMPERATURE-PRESSURE-TIME RELATIONS IN A CLOSED CRYOGENIC CONTAINER. Sidney C. Huntley. February 1958. 21p. diagrs. (NACA TN 4259)

An experimental study with liquid nitrogen in a closed container showed that surface temperature controlled the tank pressure and verified the existence of temperature gradients that accounted for the increase in pressure above that calculated from the average liquid temperature. Stirring the liquid to equalize liquid temperatures caused a pressure reduction to the calculated value. Mixing the vapor increased the direct heat flow to the stable liquid layer at the surface, which resulted in an increase in pressure.

THE EFFECT OF A WIND GRADIENT ON THE RATE OF CLIMB OF AN AIRCRAFT. W. A. Mair, Cambridge University. 1957. 9p. ARC R & M 2953. Supersedes ARC 15,862; Perf.1086(rev.). (Ask for N-27846Y*)

The behavior of an aircraft climbing in the presence of a wind gradient is analyzed by a method similar to that used in R & M 379, but with fewer simplifying assumptions. It is shown that the result obtained in the earlier paper is only correct if the angle of climb is small and if the true airspeed is constant during the climb. With the climb techniques that are now usual, however, the true airspeed is not constant during the climb; with typical subsonic aircraft the effect of this is to change the correction due to a wind gradient by about 10 percent. For aircraft

*AVAILABLE ON LOAN ONLY.

BRITISH REPORTS

climbing at supersonic speeds the effect of acceleration may be much greater than this. Since the percentage change of rate of climb due to a given wind gradient is approximately proportional to the flight speed, the effect does not become less important as aircraft speeds increase. Moreover, wind gradients having a significant effect on the rate of climb are not confined to low altitudes. For a modern high-speed aircraft it is shown that the wind gradient may change the rate of climb by 20 percent or more.

INTERFERENCE CORRECTIONS FOR ASYMMETRICALLY LOADED WINGS IN CLOSED RECTANGULAR WIND TUNNELS: H. C. Garner and W. E. A. Acum, National Physical Laboratory. 1957. 38p. diagrs., tabs. ARC R & M 2948. Supersedes ARC 16,153; FM 1951; S & C 2805. (Ask for N-30610X*)

The problem of tunnel interference on a complete lifting wing fitted with ailerons is considered in relation to aerodynamic measurements on a six-component balance. Asymmetric loading introduces corrections to the incidence of the wing, the drag, and the rolling, pitching, and yawing moments. The basic theory of wall interference in closed rectangular tunnels is outlined. The tunnel-induced upwash is expressed in terms of the loading on the wing and four quantities dependent on the shape of tunnel. One section describes how the evaluation of tunnel interference is conveniently linked with Multhopp's lifting-surface theory to determine corrections to incidence, pitching moment, and rolling moment. The corrections are applied to an arrowhead wing with various ailerons in a duplex tunnel.

THE EFFECT OF THE GROUND ON A HELICOPTER ROTOR IN FORWARD FLIGHT. I. C. Cheeseman and W. E. Bennett. 1957. 10p. diagrs. ARC R & M 3021; 17,772; 17,937. Supersedes AAEE/Res/288 and AAEE Airborne Experimental Div. Note 18. (Ask for N-38759X*)

An approximate method of estimating the effect of the ground on the lift of a rotor at any forward speed is described. Flight tests on several different helicopters show reasonable agreement with the theory. Curves are given showing the relation between thrust, height, speed, and power. The theory has been extended to include the effect of a variation in blade loading coefficient and shows that, within the range that this parameter takes on present single-rotor helicopters, the effect is small. The effect of fitting flat surfaces beneath the rotor is also considered.

THE CALCULATION OF THE PRESSURE DISTRIBUTION ON THE SURFACE OF THICK CAMBERED WINGS AND THE DESIGN OF WINGS WITH GIVEN PRESSURE DISTRIBUTION. J. Weber. 1957. 59p. diagrs., tabs. ARC R & M 3026; ARC 17,972. Supersedes RAE Aero 2548. (Ask for N-40307X*)

This report deals with thick cambered wings of any section shape and with the inverse problem of designing airfoils which have prescribed velocity distributions. As the general method is so organized that particular solutions are built up of a few basic solutions, so also in the present case, only the basic cases of the two-dimensional airfoil and the center section of swept wings need be treated in detail. A simple calculation method, suitable for practical application, is derived by approximating to the integral expressions for the unknown quantities (velocity increment or section ordinate or the slope of the section) by finite sums over the given section ordinates or velocity increments and tabulating the required coefficients. For the two-dimensional airfoil, a comparison is made with exact results which shows that the accuracy is sufficient for practical purposes.

CURRENT TESTS ON LAMINAR-BOUNDARY-LAYER CONTROL BY SUCTION THROUGH PERFORATIONS. S. F. J. Butler. 1957. 21p. diagrs., tab. ARC R & M 3040; 17,902. Supersedes RAE Tech.Note Aero 2375. (Ask for N-40342X*)

No attempt was made to obtain full-chord laminar flow, as this had been shown previously to be a natural consequence of applying a suitable suction distribution, providing turbulent wedges did not result from oversuction. In the present tests, the main aim therefore was to determine the flow rates at which such wedges appeared for different arrangements of perforations. In order to simplify the test procedure, most of the results were obtained using one or more closely spaced rows of perforations at a single chordwise station on an otherwise plain wing. A method is given, supported by some experimental evidence, for predicting the perforation spacing which would be required in a full-chord application from the results thus obtained at a single chordwise station.

AN EXTENSION OF THE HYDRODYNAMIC SOURCE-SINK METHOD FOR AXISYMMETRIC BODIES.
A. H. Armstrong. 1957. 18p. diagrs., tab.
ARC R & M 3020; ARC 17,787. Supersedes ARE Rept. 59/54. (Ask for N-44352X*)

Real flow patterns are produced by formally placing a pair of conjugate complex sources at conjugate complex points on the axis of symmetry. These complex singularities are shown to be equivalent to a nonuniform distribution of real doublets on a real disk. Reciprocal relationships are formulated between these new singularities and the well-known simple source ring and vortex ring. While the latter are simpler physically, the new type of singularity is easier to handle in mathematical analysis, involving only square roots instead of elliptic integrals. Sufficient conditions are determined under which an axisymmetric body may be generated by a real distribution of sources and sinks along the axis of symmetry, and the formula for the source intensity is given when these conditions are satisfied.

ELASTIC MODULI AND TENSILE PROPERTIES OF TITANIUM-CARBON AND TITANIUM-ALUMINIUM-CARBON ALLOYS. H. Brooks, G. I. Lewis, and J. I. M. Forsyth. June 1957. 19p. diagrs., photos., tabs. RAE Tech.Note Met. 265. (Ask for N-57935*)

Tensile tests and dynamic measurements on alloys hot-rolled to 0.06-in. strip confirmed the beneficial effect of carbon additions on the tensile and shear moduli of titanium. A Ti-2.5 percent C alloy has E's of 19.4 and 15.7 x 10^6 lb/in.^{2} at 20° and 400° C but its strength and elongation are rather low. Surface cracking of high-carbon alloys during hot-rolling can be prevented by cladding with unalloyed titanium but carbon is considered unlikely to be used as a modulus-raising addition in commercial sheet alloys unless its effect on service temperature ductility can be lessened. Ternary alloys containing both carbon and aluminum, in amounts sufficient to give a significant improvement in modulus, are brittle.

NEAR FIELD JET NOISE. M. O. W. Wolfe. (Paper presented at Structures and Materials Panel, Advisory Group for Aeronautical Research and Development, Copenhagen, April 1957.) September 1957. 43p. diagrs., photo. RAE Tech.Note Structures 228. (Ask for N-57937*)

This paper deals with the subject of jet engine noise in relation to its effects on aircraft structures. Near field noise measurements are described for a range of jet shear velocities on two representative turbojet engines, one of them operating with an afterburner. Contours of equal noise pressure in the horizontal plane containing the axis of the jet are presented for a range of shear velocity for overall noise pressure and for noise pressures in 1/3 octave frequency bands in the noise spectra. In the velocity range 790 to 1800 feet per second, 400 cps is the dominant frequency. At most velocities the noise pressures at this frequency are about 10 decibels less than the corresponding overall noise pressures. The increase in noise level due to reheat is not as great as would have been predicted from a consideration of the noise level trends at much lower values of velocity without reheat.

Royal Aircraft Establishment (Gt. Brit.)
MEASUREMENTS OF THE EFFECT OF SURFACE COOLING ON BOUNDARY LAYER TRANSITION ON A 15° CONE. PART I - TESTS AT M = 2 AND 3 IN AN 8 IN. x 9 IN. WIND TUNNEL AT R.A.E./ BEDFORD. A. C. Browning, J. F. W. Crane, and R. J. Monaghan. September 1957. 41p. diagrs., photos., tab. RAE Tech.Note Aero 2527. (Ask for N-58036, pt.1*)

Tests on a steel cone of 15° included angle, cooled internally by the circulation of cold alcohol, gave the results that when the ratio (surface temperature ahead of transition)/(surface temperature for zero heat transfer) was reduced from 1.0 to 0.88, the transition Reynolds number at zero incidence was increased by a factor of about 1.8 for a local Mach number (M_1) of 1.86 and by a factor of 1.24-1.43 for $M_1 = 2.81$. Simultaneous records of transition position on the top and bottom generators of the cone were obtained in all cases, using the shadowgraph technique. When the cone was set at an incidence of 2°, transition on the windward generator moved aft with cooling at about the same rate as was found in the zero incidence tests (at each Mach number).

THE MECHANICAL PROPERTIES OF NIMONIC 80, 90, AND 100 SHEET AT ROOM AND ELEVATED TEMPERATURES. D. C. Hayward. June 1957. 19p. diagrs., tabs. RAE Tech.Note Met. 266. (Ask for N-58038*)

Properties were determined in tension and compression for fully heat-treated Nimonic 80, 90, and 100 sheet at room temperature and in tension only at 200°, 400°, and 600° C. The effect of exposure to 600° C for 1000 hrs was examined. On annealed material at room temperature longitudinal and transverse minimum radius bend tests were made and on tensile specimens local and general elongations measured. In general, strength and stiffness were reduced slightly with rise in testing temperature throughout the range investigated; transverse values, determined at room temperature only, corresponded closely with values from longitudinal tests. Room temperature bend tests produced close bends without visible cracks except for Nimonic 100 which cracked slightly. Tensile strength at 600° C was slightly increased by soaking at this temperature for 1000 hrs.

CONCEPT OF COMPLEX STIFFNESS APPLIED TO PROBLEMS OF OSCILLATIONS WITH VISCOUS AND HYSTERETIC DAMPING. S. Neumark. September 1957. 45p. diagrs. RAE Aero 2592. (Ask for N-58520*)

The concept of complex stiffness in problems of oscillations with viscous or structural (hysteretic) damping is often used in a wrong way, leading to erroneous solutions. It is shown in the paper that correct expressions for complex stiffness are different in the cases of forced and free oscillations. All fundamental cases for a single degree of freedom are critically reexamined and compared, and fallacious solutions eliminated. The law of hysteretic damping being only known for a simple harmonic oscillation, all problems involving decaying oscillations, or more than one oscillatory mode, can only be treated tentatively at present, until the general law is found. This requires further experimental work.

THE DESIGN OF LONGITUDINALLY STIFFENED PANELS. H. L. Cox and G. Angell, National Physical Laboratory. January 19, 1955. 13p. diagrs. ARC 17,315; Strut 1766. (Ask for N-58533*)

The purpose of this investigation is to present the conditions governing the buckling of panels stiffened only longitudinally in a form suitable for design. Diagrams are presented for a long, flat, rectangular panel with its edges simply supported and stiffened by one stringer midway between its edges. The effect of two or more stringers is briefly reviewed. It is concluded that it is always advantageous to use at least one stringer and the weight thereby saved may amount to 30 percent. The form of the single stringer required is no more than a plain rectangular section. With two stringers the stringer section required is more elaborate, and a high stiffening ratio with three or more stringers needs so efficient a stringer section that the use of more than two stringers is seldom likely to be economical.

A TITANIUM VANADIUM ALLOY. A. R. G. Brown and P. M. R. Gates. July 1957. 13p. diagrs., photos., tabs. RAE Tech. Note Met 259.
(Ask for N-58534*)

An alloy of 56.8 percent Ti, 37.4 percent V, 5.4 percent Al, and 0.67 percent C has been made from pure materials, fabricated and tested at room temperature and 400° C. The ultimate tensile strength of the alloy is 67.2 tons/sq in. at room temperature and 60.5 tons/sq in. at 400° C. The Young's modulus of the alloy is 15.7×10^6 psi and 14.4×10^6 psi at room temperature and 400° C, respectively. The room temperature density was 4.94 g/cm^3. The properties of pure vanadium cold-worked (90 percent) sheet were also investigated. The ultimate strength of the sheet was 71.5 tons/sq in. at 20° C and 61.2 tons/sq in. at 400° C, and the Young's modulus at these temperatures 17.6×10^6 psi and 17.1×10^6 psi, respectively.

AN APPROXIMATE METHOD OF CALCULATING THE LAMINAR BOUNDARY LAYER IN TWO-DIMENSIONAL INCOMPRESSIBLE FLOW. M. R. Head, University of Cambridge. March 26, 1957. 87p. diagrs. ARC 19,154; FM 2523.
(Ask for N-58536*)

In the present approximate method the use of a doubly infinite family of boundary-layer velocity profiles enables the momentum and energy integral equations of the boundary layer to be satisfied exactly, together with the first boundary condition at the surface. The principal characteristics of the velocity profiles used have been calculated, and are presented graphically in a series of charts which enable calculations to be carried out with a minimum of labor. Several examples of boundary-layer flow have been worked out in detail by the use of the method, and agreement with known exact solutions is in most cases extremely satisfactory.

THE WAVE DRAG AT ZERO LIFT OF SLENDER DELTA WINGS AND SIMILAR CONFIGURATIONS. M. J. Lighthill. May 20, 1955. 15p. diagrs. ARC 17,646; FM 2254. (Ask for N-58537*)

This paper is concerned with bodies which terminate in a straight trailing edge at right angles to the stream, with a small but finite trailing-edge angle (which may vary along with it). This class of bodies includes delta wings. Bodies terminating in two such trailing edges at right angles to one another, or in a cylindrical section with two or four fins attached, are also treated.

STATIC RESPONSE OF A HEMISPHERICAL-HEADED YAWMETER AT HIGH SUBSONIC AND TRANSONIC SPEEDS. P. G. Hutton. August 1957. 24p. diagrs. RAE Tech. Note Aero 2525. (Ask for N-58540*)

Details are given of the static calibration of a hemispherical-headed differential pressure yawmeter, in the Mach number range from 0.6 to 1.2; the instrument has a central pitot pressure hole and two pairs of holes in perpendicular planes for flow direction measurement. The results show that the sensitivity to yaw (for angles up to 8°) as determined from pressure differences between opposing holes, varies smoothly with Mach number at transonic speeds; the sensitivity is little affected by a crossflow normal to the line joining the holes.

DESIGN OF WARPED SLENDER WINGS WITH THE ATTACHMENT LINE ALONG THE LEADING EDGE. J. Weber. September 1957. 83p. diagrs., tabs. RAE Tech. Note Aero 2530. (Ask for N-58542*)

Wings with unswept trailing edge but otherwise arbitrary plan form which have, at the design lift coefficient, zero load along the leading edge and a near planar vortex sheet from the trailing edge are considered. The wing can have an arbitrary chordwise curvature on which a spanwise curvature is superposed so that in any spanwise section the wing is straight over the inner part of the wing and curved over the portion near to the leading edges; the position of this change can vary arbitrarily in the chordwise direction. Formulas and working charts are given for determining the local load coefficient (and with it the streamwise velocity component), the spanwise velocity component, the total lift coefficient, and the total drag. Numerical examples for the gothic plan form are given to illustrate some of the effects of the various parameters on the load distribution, the section shapes, and the drag.

Advisory Group for Aeronautical Research and Development. THE INFLUENCE OF DRAG CHARACTERISTICS ON THE CHOICE OF LANDING APPROACH SPEEDS. D. Lean and R. Eaton. (Presented at 10th meeting of Flight Test Techniques Panel, London, May 20-24, 1957.) May 1957. 24p. diagrs., tabs. AGARD Report 122.
(Ask for N-54139X)

A study has been made of the lift-drag characteristics of 19 jet aircraft which have minimum comfortable approach airspeeds that are fairly well established. On about half these aircraft, drag effects, which determine speed stability, were stated to limit the approach airspeeds, though there was naturally some lack of unanimity as to the level of the effect which could be classed as tolerable. Limiting values of speed stability are proposed for the three types of landing approach used for carrier, airfield, and instrument landings. The speeds corresponding to these stability levels are in fair agreement with those actually used, even for those aircraft whose approach speeds were not primarily limited by drag effects. It is considered that drag effects must be taken into account in estimating approach airspeeds, and that this process materially improves the prediction of approach speeds for the latest types of aircraft. Further data should be collected and analyzed in order to confirm or modify the form or level of the proposed limits.

Advisory Group for Aeronautical Research and Development. TUBE WIND TUNNEL - A SPECIAL TYPE OF BLOWDOWN TUNNEL. H. Ludwieg. (Presented at 11th meeting of Wind Tunnel and Model Testing Panel, Scheveningen, July 8-12, 1957.) July 1957. 11p. diagrs., photo. AGARD Report 143. (Ask for N-55127X)

A short description of the tube wind tunnel is given. This tunnel is a special type of blowdown tunnel, the air container of which consists of a long cylindrical tube. The air in the tube is preaccelerated by an expansion wave before entering the nozzle of the tube tunnel. In this way a good constancy of stagnation pressure and of stagnation temperature is reached without the use of any control valve and heat accumulator. The influence of the wall friction in the tube on the stagnation pressure and stagnation temperature in the test section is discussed. Experiments carried out in order to investigate this effect are reported. They show good agreement with the theoretical results. Means to reduce or to compensate the influence of the friction at the tube wall are dealt with. Possibilities for application of the tube tunnel are mentioned.

CN-58000

Advisory Group for Aeronautical Research and Development. A CLASSIFICATION SYSTEM FOR UNPREPARED LANDING AREAS. David P. Samson, Jr., United States Air Force. (Presented at 10th meeting of Flight Test Techniques Panel, London, May 20-24, 1957.) May 1957. 11p. tabs. AGARD Report 129. (Ask for CN-58000)

Describes a method of classifying any unprepared landing area under the main headings of (1) landing area, (2) terrain configuration, (3) surface roughness, and (4) soil description and bearing capacity. This classification, with subdivisions, results in a numerical "terrain designator" and should assist when stating design requirements for new aircraft.

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - TWISTED AND CAMBERED TRIANGULAR WING OF ASPECT RATIO 2 WITH NACA 0003-63 THICKNESS DISTRIBUTION. Charles F. Hall and John C. Heitmeyer. June 12, 1951. 24p. diagrs., photo., tab. (NACA RM A51E01)

This report presents the results of an investigation to ascertain the lift, drag, and pitching moment of a wing-body combination having a triangular wing of aspect ratio 2 with NACA 0003-63 thickness distribution in streamwise planes and twisted and cambered for a nearly elliptical span load distribution. Results are shown for Mach numbers from 0.60 to 0.90 and from 1.30 to 1.70 at Reynolds numbers of 3.0 million and 7.5 million.

NACA RM A52B08

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - TWISTED AND CAMBERED TRIANGULAR WING OF ASPECT RATIO 2 WITH NACA 0005-63 THICKNESS DISTRIBUTION. John C. Heitmeyer and Robert B. Petersen. April 1952. 20p. diagrs., tabs. (NACA RM A52B08)

This report presents the results of an investigation to ascertain the lift, drag, and pitching moment of a wing-body combination having a triangular wing of aspect ratio 2 with NACA 0005-63 thickness distribution in streamwise planes and twisted and cambered for a nearly elliptical span load distribution. Results are shown for Mach numbers from 0.60 to 0.90 and from 1.30 to 1.90 at Reynolds numbers of 3.0, 4.9, and 7.5 million.

NACA RM A53B11

A THEORETICAL STUDY OF THE EFFECT OF CONTROL-DEFLECTION AND CONTROL-RATE LIMITATIONS ON THE NORMAL ACCELERATION AND ROLL RESPONSE OF A SUPERSONIC INTERCEPTOR. Howard F. Matthews and Stanley F. Schmidt. April 1953. 28p. photos., diagrs., tabs. (NACA RM A53B11)

A theoretical study of the effects of limiting the control motion of a representative supersonic interceptor showed that for the particular conditions chosen, the normal-acceleration and roll response times decreased at a diminishing rate with increases in the limited rate of control motion, and that little advantage is gained in exceeding a rate of about 200° per second. A method of simulating a first-order servo with control-deflection limits is given in an appendix.

NACA RM A53B16

COMPARISON OF THE AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF A PLANE WING AND A CAMBERED AND TWISTED WING, BOTH HAVING 45° OF SWEEPBACK AND AN ASPECT RATIO OF 6. George H. Holdaway. May 1953. 49p. diagrs., photos. (NACA RM A53B16)

A transonic investigation was made by the free-fall technique of the lift, drag, and pitching moment of a plane wing and a cambered and twisted wing, each having an aspect ratio 6, taper ratio of 0.5, and swept back 45°. The wings were mounted on similar fuselage-tail combinations of a fineness ratio of 12.4 with tail surfaces also swept back 45°. Aerodynamic coefficients were determined for the two wings and for the complete model over a Mach number range of 0.86 to 1.08, Reynolds numbers of 3,000,000 to 5,000,000, and angles of attack of approximately 0° to 12°. Wing buffet boundaries were also determined.

NACA RM A54B15

OPTIMUM LIFTING BODIES AT HIGH SUPERSONIC AIRSPEEDS. Meyer M. Resnikoff. May 1954. 22p. diagrs., photo. (NACA RM A54B15)

Optimum lifting bodies at high supersonic airspeeds are determined with the aid of Newtonian impact theory. Simple wedges are found to fall in the category of such bodies. Results of tests at a Mach number of 5 of several wedges and corresponding bodies of revolution having fineness ratios from 3 to 7 show that the wedges have up to 100-percent-higher lift-drag ratios.

UNAVAILABLE; contains proprietary or obsolete information.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A55D11

INVESTIGATION OF THE EFFECTS OF AN AIRFOIL SECTION MODIFICATION ON THE AERODYNAMIC CHARACTERISTICS AT SUBSONIC AND SUPERSONIC SPEEDS OF A THIN SWEPT WING OF ASPECT RATIO 3 IN COMBINATION WITH A BODY. David Graham and William T. Evans. June 1955. 46p. diagrs., tabs. (NACA RM A55D11)

The basic wing had a taper ratio of 0.4, leading-edge sweep of 45°, and an NACA 64A006 section normal to the quarter-chord line. The modification consisted of greatly increased leading-edge radius and slight forward camber. A large-scale wind-tunnel model was tested at Mach numbers from 0.06 to 0.31 and Reynolds numbers from 4.4×10^6 to 21×10^6, and a small-scale wind-tunnel model was tested at Mach numbers from 0.6 to 1.9 and Reynolds numbers from 2.9×10^6 to 5.7×10^6. Lift, drag, and pitching moment were measured.

NACA RM A56B15

EFFECT OF MACH NUMBER ON BOUNDARY-LAYER TRANSITION IN THE PRESENCE OF PRESSURE RISE AND SURFACE ROUGHNESS ON AN OGIVE-CYLINDER BODY WITH COLD WALL CONDITIONS. Robert J. Carros. April 1956. 30p. diagrs., photos. (NACA RM A56B15)

Boundary-layer transition Reynolds number was measured in free flight on a high-fineness-ratio fin-stabilized ogive-cylinder body at Mach numbers from 1.8 to 7.4 at a constant length Reynolds number of 13.8 million. The wall to free-stream temperature ratio was 1.0 below $M = 4.5$ and was 1.8 at higher Mach numbers. The effects of roughness and pressure rise (associated with angle of attack) were investigated.

NACA RM A56B17

DATA FROM LARGE-SCALE LOW-SPEED TESTS OF AIRPLANE CONFIGURATIONS WITH A THIN 45° SWEPT WING INCORPORATING SEVERAL LEADING-EDGE CONTOUR MODIFICATIONS. William T. Evans. May 1956. 110p. diagrs., photo., tabs. (NACA RM A56B17)

The basic wing of aspect ratio 3, taper ratio 0.4, and 45° of sweep, had an NACA 64A006 section. The modifications consisted of increases of leading-edge radius, both with and without camber and spanwise section variation. The wing and body were tested with and without vertical and horizontal tails. The basic wing was also tested alone. Fences, chord extensions, split flaps, and ailerons were tested. Six-component force data were obtained at Reynolds numbers from 4.4×10^6 to 21×10^6.

NACA RM A56B21

LIGHT DIFFUSION THROUGH HIGH-SPEED TURBULENT BOUNDARY LAYERS. Howard A. Stine and Warren Winovich. May 1956. 46p. diagrs., photos., tabs. (NACA RM A56B21)

Optical transmission characteristics of turbulent boundary layers were measured photometrically with unpolarized white light for ranges of Mach number from 0.4 to 2.5, free-stream density from 0.12 to 0.93 sea-level density atmospheres, and boundary-layer thickness from 1-1/2 to 4-1/2 inches. The deterioration of resolving power of optical equipment due to scattering is related to the absolute change in mean density integrated along the radiation propagation path. Analysis indicates that photometric surveys of a scattered light field yield average values of the integral scale and intensity of density fluctuations.

NACA RM A56B27

INVESTIGATION OF THE USE OF AREA SUCTION TO INCREASE THE EFFECTIVENESS OF TRAILING-EDGE FLAPS OF VARIOUS SPANS ON A WING OF 45° SWEEPBACK AND ASPECT RATIO 6. Roy N. Griffin, Jr., and David H. Hickey. June 1956. 64p. diagrs., photo., tabs. (NACA RM A56B27)

Tests were made of area-suction inboard trailing-edge flaps of various deflection and span. The flaps of 0.50 span and 46° deflection attained the flap lift increment predicted by inviscid-flow theory. The flaps of longer span or greater deflection gave lift increments somewhat lower than theoretical. When the area-suction flaps were deflected differentially for lateral control they produced about 80 percent of theoretical rolling-moment coefficient and appear feasible as a means of roll control.

NACA RM E9B03

EXPERIMENTAL PRESSURE DISTRIBUTION ON AN ASYMMETRICAL NONCONICAL BODY AT MACH NUMBER 1.90. DeMarquis D. Wyatt. February 24, 1949. 58p. diagrs., photos., tabs. (NACA RM E9B03)

An investigation of pressure distribution on an asymmetrical nonconical body was conducted at Mach number 1.90 over wide range of angles of attack and yaw. Pressure distributions conformed to anticipated trends. Boundary-layer separation apparently occurred from upper surface at angles of attack above 24° and from lower surface at -15°. No separation from sides of body was evident at yaw angles up to 12°.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E52B08

COMPONENT AND OVER-ALL PERFORMANCE EVALUATION OF AN AXIAL-FLOW TURBOJET ENGINE OVER A RANGE OF ENGINE-INLET REYNOLDS NUMBERS. Curtis L. Walker, S. C. Huntley, and W. M. Braithwaite. July 1952. 42p. diagrs., tabs. (NACA RM E52B08)

The performance of an axial-flow turbojet engine was investigated over a range of engine-inlet Reynolds number indices which includes a wide variation in altitude and flight Mach number. Component and overall performance variables are presented as functions of corrected engine speed and Reynolds number index. Combustion efficiency is presented as a function of combustor-inlet conditions. Reduced Reynolds number had the net effect of increasing corrected fuel flow but had no apparent effect on the corrected jet-thrust parameter. A method is presented whereby conventional performance parameters such as net thrust and specific fuel consumption may be obtained for any flight condition within the range of Reynolds numbers investigated.

NACA RM E52B19

TRANSONIC FREE-FLIGHT DRAG RESULTS OF FULL-SCALE MODELS OF 16-INCH-DIAMETER RAM-JET ENGINES. Wesley E. Messing and Loren W. Acker. April 1952. 17p. diagrs. (NACA RM E52B19)

A free-flight investigation on two full-scale model 16-inch-diameter ram-jet engines was conducted over a Mach number range of 0.6 to 1.43 and an altitude range of 35,000 feet to sea level in order to evaluate the component drag coefficients. At a Mach number of 1.15, the model with the larger restrictor plug encountered the highest total drag coefficient, 0.63. The external drag coefficient increased from a subsonic value of 0.105 to a maximum value of 0.215 at a Mach number of 1.30 as compared with an increase of from 1.105 at a Mach number of 0.90 to 0.17 at a Mach number of 1.30 for the other model.

NACA RM E52B22

PERFORMANCE OF AN IMPULSE-TYPE SUPERSONIC COMPRESSOR WITH STATORS. John F. Klapproth, Guy N. Ullman, and Edward R. Tysl. April 1952. 22p. diagrs., photo. (NACA RM E52B22)

An impulse-type supersonic compressor rotor with stators was tested in Freon-12 over a range of equivalent tip speeds and weight flows. The performance characteristics with a shock stabilized in either the stator or both rotor and stator were investigated. Pressure recoveries across the stators when diffusing from supersonic to subsonic Mach numbers were obtained.

NACA RM E52B25

ALTITUDE PERFORMANCE INVESTIGATION OF TWO FLAME-HOLDER AND FUEL-SYSTEM CONFIGURATIONS IN SHORT AFTERBURNER. S. C. Huntley and H. D. Wilsted. May 1952. 41p. diagrs., photos., tab. (NACA RM E52B25)

The performance of two dissimilar flame-holder and fuel-system configurations was evaluated in a short afterburner. The engine was operated at rated speed over a range of altitudes from 10,000 to 45,000 feet and flight Mach numbers from 0.4 to 1.0 and a range of afterburner fuel-air ratios. The altitude operating limits and the altitude performance of the V-gutter flame holder were found superior to those of the H-gutter configuration. Spontaneous ignition was obtained with the V-gutter configuration but the H-gutter configuration required the use of a torch ignition.

NACA RM E53B02

ALTITUDE STARTING CHARACTERISTICS OF AN AFTERBURNER WITH AUTOIGNITION AND HOT-STREAK IGNITION. P. E. Renas, R. W. Harvey, Sr., and E. T. Jansen. April 1953. 25p. diagrs., photos., tab. (NACA RM E53B02)

An investigation was conducted in an altitude test chamber at the NACA Lewis Laboratory to determine the altitude starting characteristics of an afterburner with autoignition and with hot-streak ignition. Transient afterburner ignition data were obtained over a range of altitudes from 30,000 to 50,000 feet at a flight Mach number of 0.60. Afterburner ignition with a torch igniter located axially at approximately the midpoint of the combustion chamber was possible over the entire altitude range, but ignition with a torch igniter located in the transition section 1-5/8 inches upstream of the turbine stators proved unsatisfactory at an altitude of 50,000 feet due to the inability to obtain flame through the turbine. Increasing the afterburner-inlet total pressure at a constant afterburner fuel-air ratio decreased the afterburner ignition time. Hot-streak ignition was possible within 2 seconds after the time required to obtain the preset, normal afterburner fuel pressure, whereas autoignition required from 4 to 7 seconds for the range of altitudes investigated. Following ignition there was a period of oscillatory operation existing in the engine afterburner before steady-state operation was attained. The time required for steady-state stable operation decreased as afterburner inlet total pressure increased. The duration of oscillations also decreased with hot-streak ignition because the fuel-air mixture was ignited before a large volume of combustible mixture was accumulated in the afterburner.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E53B09

DESIGN PROCEDURE AND LIMITED TEST RESULTS FOR A HIGH SOLIDITY, 12-INCH TRANSONIC IMPELLER WITH AXIAL DISCHARGE. Linwood C. Wright and Karl Kovach. April 1953. 37p. photos., diagrs., tab. (NACA RM E53B09)

An approximate inverse design procedure based on the assumption of axisymmetric, nonviscous flow is presented along with limited experimental data obtained from a high solidity, 12-inch transonic impeller. The design procedure was utilized for the design of a 12-inch 0.40 hub-tip ratio impeller with sweptback leading edges to operate at 1200 feet per second equivalent tip speed. Because of an outlet annulus restriction and a partial structural failure which occurred before alterations could be made, the design speed experimental performance was restricted to a pressure ratio of 2.164 at an equivalent weight flow of 26.47 pounds per second (33.71 lb/sec-sq ft) and an impeller adiabatic efficiency of 0.81 percent.

NACA RM E54A06

HIGH-ALTITUDE PERFORMANCE OF 9.5-INCH-DIAMETER TUBULAR EXPERIMENTAL COMBUSTOR WITH FUEL STAGING. Wilfred E. Scull. March 1954. 55p. diagrs., photos., tabs. (NACA RM E54A06)

An experimental 9.5-inch-diameter tubular combustor was developed; this combustor embodied adjacent fuel-rich and air-rich regions and axial staging of liquid fuel introduction. Axial staging of fuel introduction increased combustion efficiencies at high fuel-air ratios and high air-flow rates. At all combustor inlet pressures investigated, the experimental combustor operated with higher combustion efficiencies than a current-production-model tubular combustor of the same diameter. At combustor-inlet conditions simulating 85 percent rated speed operation of a 5.2-pressure-ratio reference engine at a flight Mach number of 0.6 and an altitude of 56,000 feet, the experimental combustor operated at fuel-air ratios from 0.0035 to 0.029 with a maximum combustion efficiency of 94 percent and a maximum combustor-outlet total temperature of 1925° F. Altitude flight performance in the reference engine at rated speed was estimated to result in combustion efficiencies of 97 percent or greater at altitudes up to 59,000 feet. Isothermal combustor total-pressure loss, which was somewhat greater than that of the production-model reference combustor, was approximately 7 percent of the combustor-inlet total pressure for a reference velocity of 100 feet per second. Individual combustor outlet total temperatures at most operating conditions were within ±200° F of the mean outlet total temperature.

NACA RM E54A29

PHOTOGRAPHIC STUDY OF ROTARY SCREAMING AND OTHER OSCILLATIONS IN A ROCKET ENGINE. Theodore Male, William R. Kerslake, and Adelbert O. Tischler. May 1954. 37p. diagrs., photos. (NACA RM E54A29)

Rocket combustion instabilities due to lateral and longitudinal oscillations were photographed through transparent plastic chambers by streak photography and high-speed frame photography. The streak photographs show longitudinal oscillations and attendant shock waves of approximately 1000 cycles per second; they also show strong lateral oscillations of 4000 to 6000 cycles per second as well as weak lateral oscillations of approximately 10,000 cycles per second. The 40,000 frame-per-second photographs show that some of the lateral oscillations are rotary, and the pressure measurements indicate that the disturbance was a rotary pressure wave. Qualitative heat-transfer measurements, based on plastic erosion rates, indicate that the rotary oscillation causes heat transfer approximately five or six times the heat transfer of normal combustion.

NACA RM E54B03

EFFECT OF NOZZLE SECONDARY FLOWS ON TURBINE PERFORMANCE AS INDICATED BY EXIT SURVEYS OF A ROTOR. Warren J. Whitney, Howard A. Buckner, Jr., and Daniel E. Monroe. April 1954. 11p. diagrs. (NACA RM E54B03)

Detailed circumferential and radial surveys of total pressure and total temperature were made downstream of the turbine rotor of a high-speed, high-specific-mass-flow turbine at design operating conditions. The results of these surveys, when plotted as efficiency contours over the survey range of approximately 1-1/4 nozzle passages, indicated that large circumferential-loss gradients existed downstream of the turbine rotor, effecting a variation in the local efficiency of 14 points. These losses were caused by disturbances originating in the nozzle and probably represent the effect of nozzle secondary-flow vortices and wakes carrying through the rotor. From the indications of the survey results, it was concluded that losses in the nozzle blades due to secondary-flow vortices and wakes, although normally small, can induce much greater losses in the turbine rotor and can cause an appreciable effect on the overall turbine performance.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E54B09

PERFORMANCE CHARACTERISTICS OF SEVERAL SHORT ANNULAR DIFFUSERS FOR TURBOJET ENGINE AFTERBURNERS. William E. Mallett and James L. Harp, Jr. May 1954. 31p. diagrs., photo. (NACA RM E54B09)

Recent research has been directed toward the development of a short annular diffuser which would have low pressure loss and provide a uniform (flat) velocity profile at the diffuser exit. The performance characteristics reported herein were made in four short annular diffusers with different diffuser passage area variations and with various combinations of straightening vanes, vortex generators, splitters, and boundary-layer suction for flow control. Elimination of whirl (approximately 20° at the turbine discharge of the engine used for this investigation) provided the greatest single gain by reducing the tailpipe pressure loss 2.4 percent, although with the elimination of whirl the flow separated severely from the curved inner body. The variation of diffusion rate investigated did not significantly change the tailpipe pressure loss, although the diffuser exit velocity profile varied considerably. Splitters improved the generators and boundary-layer removal gave no improvement.

NACA RM E54B12

EFFECT OF JET-NOZZLE-EXPANSION RATIO ON DRAG OF PARABOLIC AFTERBODIES. Gerald W. Englert, Donald J. Vargo, and Robert W. Cubbison. April 1954. 26p. diagrs., photos. (NACA RM E54B12)

The interaction of the flow from one convergent and two convergent-divergent nozzles on parabolic afterbodies was studied at free-stream Mach numbers of 2.0, 1.6, and 0.6 over a range of jet pressure ratio. The influence of the jet on boattail and base drag was very pronounced. Study of the total external afterbody drag values at supersonic speeds indicated that over most of the high-pressure-ratio range, increasing the nozzle design expansion ratio increased the drag even though the boattail area was reduced. Increasing the pressure ratio tended to increase slightly the total-drag increment caused by angle-of-attack operation.

NACA RM E54B16

LOW-VELOCITY TURNING AS A MEANS OF MINIMIZING BOUNDARY-LAYER ACCUMULATIONS RESULTING FROM SECONDARY FLOWS WITHIN TURBINE STATORS. Warner L. Stewart and Robert Y. Wong. May 1954. 18p. diagrs., photo. (NACA RM E54B16)

A series of three single-passage nozzles, designed to turn the flow at different velocity levels but to identical outlet conditions, were investigated to determine whether secondary-flow accumulations of boundary-layer fluids within nozzles could be minimized by use of low-velocity turning. The results of the investigation indicated that this type of turning with subsequent acceleration is highly effective in minimizing secondary-flow accumulations at the corner where the section surface joins the end walls. As applied to turbine stators, gains in turbine performance may be expected, provided that the long blade surfaces required do not cause excessive wake losses and that three-dimensional effects on the boundary layer of the long blade do not appreciably increase the secondary-flow accumulations. It is to be noted that the effect of reduced secondary-flow accumulation on turbine performance to date has not been evaluated.

NACA RM E54B23

INVESTIGATION OF A TRANSLATING-CONE INLET AT MACH NUMBERS FROM 1.5 TO 2.0. L. Abbott Leissler and William H. Sterbentz. May 1954. 29p. diagrs., photos., tab. (NACA RM E54B23)

An experimental investigation of a translating-cone inlet was conducted over a Mach number range from 1.5 to 2.0 at angles of attack to 9°. A comparison of a translating-cone inlet with two fixed-geometry inlets over a specified corrected air-flow schedule showed the translating-cone inlet to have significant performance gains. Inlet performance was adversely affected by external flow reexpansion over the cone shoulder and internal flow contraction.

NACA RM E54D19

TURBOPROP-ENGINE DESIGN CONSIDERATIONS. I - EFFECT OF MODE OF ENGINE OPERATION ON PERFORMANCE OF TURBOPROP ENGINE WITH CURRENT COMPRESSOR PRESSURE RATIO. Elmer H. Davison. May 1955. 34p. diagrs. (NACA RM E54D19)

A cycle analysis of a turboprop engine with low compressor pressure ratio indicated: (1) Varying the mode of operation or exhaust-nozzle area had little effect on specific fuel consumption at high power but did result in an improvement at low power; (2) decreasing either the flight speed or altitude, in general, increases the specific fuel consumption; and (3) turbine requirements can be made less critical by using a variable nozzle area.

NACA RM E54I28a

PHOTOGRAPHIC INVESTIGATION OF AIR-FLOW PATTERNS IN TRANSPARENT ONE-SIXTH SECTOR OF ANNULAR TURBOJET-ENGINE COMBUSTOR WITH AXIAL-SLOT-TYPE AIR ADMISSION. Charles C. Graves and J. Dean Gernon. December 1954. 24p. diagrs., photos. (NACA RM E54I28a)

A photographic study was made of gross air-flow patterns in a transparent one-sixth sector of an annular turbojet-engine combustor with axial-slot-type admission at reference velocities from 26 to 72 feet per second. Photographs taken along the longitudinal plane of the combustor primary zone disclosed a low-velocity recirculation region near the fuel manifold. Large-scale, spiral air currents occurred in the combustor secondary zone where the flow patterns appeared to be markedly affected by the combustor side walls. Effects of combustor air velocity on gross flow patterns were minor.

NACA RM E55B08

CORRELATION OF TURBINE-BLADE-ELEMENT LOSSES BASED ON WAKE MOMENTUM THICKNESS WITH DIFFUSION PARAMETER FOR A SERIES OF SUBSONIC TURBINE BLADES IN TWO-DIMENSIONAL CASCADE AND FOR FOUR TRANSONIC TURBINE ROTORS. Robert Y. Wong and Warner L. Stewart. April 1955. 31p. diagrs. (NACA RM E55B08)

Analyses of losses occurring in subsonic turbine blades in two-dimensional cascade and of rotor-blade-element losses at the hub, mean, and tip radius of four transonic turbines indicate that turbine-blade profile losses based on blade wake characteristics can be correlated with suction-surface diffusion. A considerable difference was found between the level of the transonic turbine rotor-blade-element loss and the two-dimensional cascade profile loss. From an analysis at zero diffusion, it was indicated that unsteady flow effects on probe measurements and the effects of stator wake mixing losses can considerably influence the indicated rotor-blade-element losses. About four-fifths of the true rotor-blade-element loss is attributable to compressible-flow profile losses, while the remainder is attributable to rotor three-dimensional and other effects.

NACA RM E55B18

TURBOPROP-ENGINE DESIGN CONSIDERATIONS. II - DESIGN REQUIREMENTS AND PERFORMANCE OF TURBOPROP ENGINES WITH A SINGLE-SPOOL HIGH-PRESSURE-RATIO COMPRESSOR. Elmer H. Davison and Margaret C. Stalla. May 1955. 32p. diagrs., tabs. (NACA RM E55B18)

A cycle analysis of turboprop engines with high compressor pressure ratios indicated that (1) compared with a single-spool engine, a free-turbine engine is restricted in the range of turbine-inlet temperature over which it can operate, and (2) operation with variable exhaust-nozzle area is desirable in order to reduce turbine blade stress and frontal area.

NACA RM E55H01

THE RATE OF DECOMPOSITION OF LIQUID PENTABORANE FROM 85° TO 202° C. Glen E. McDonald. October 1955. 22p. diagrs., tab. (NACA RM E55H01)

The thermal stability of pentaborane was measured over a wide range of reaction rates, and the composition of the reaction products was determined. Measurements of the effect of dilution with n-heptane on stability indicate that the reaction is second-order. An activation energy of 34.2 kcal/mole was calculated for the overall reaction. From the correlation of the effect of temperature with the rate of decomposition, estimates may be made of the rate of decomposition to be expected at other temperatures.

NACA RM E56A13a

THEORETICAL PERFORMANCE OF JP-4 FUEL WITH A 70-PERCENT-FLUORINE - 30-PERCENT-OXYGEN MIXTURE AS A ROCKET PROPELLANT. I - FROZEN COMPOSITION. Sanford Gordon and Vearl N. Huff. April 1956. 38p. diagrs., tabs. (NACA RM E56A13a)

Theoretical rocket performance parameters were calculated for JP-4 fuel with a 70.37-percent fluorine and 29.63-percent oxygen oxidant. Frozen composition was assumed during the expansion process. Data were calculated for equivalence ratios of 1 to 4, chamber pressures of 300 and 600 pounds per square inch, and pressure ratios of 1 to 1500. A correlation is given which permits the determination of performance for a wide range of chamber pressures. The maximum values of specific impulse for chamber pressures of 600 and 300 pounds per square inch absolute (40.83 and 20.41 atmospheres) and an exit pressure of 1 atmosphere were 301.1 and 278.2, respectively, at 20.7 weight percent fuel.

NACA RM E56A19

A STUDY OF FUEL-NITRIC ACID REACTIVITY. Charles E. Feiler and Louis Baker, Jr. April 1956. 48p. diagrs., photo., tabs. (NACA RM E56A19)

The relative reactivities of six fuels with red fuming nitric acid (19 percent NO_2) were determined in a 40-pound-thrust rocket engine with rapid liquid-phase mixing. The combustion-chamber characteristic length required to obtain 97 percent of maximum experimental characteristic exhaust velocity was used as the measure of reactivity. Hydrazine, trimethyl-trithiophosphite, furfuryl alcohol, unsymmetrical dimethyl-hydrazine, allylamine, and o-toluidine were studied; reactivity decreased in that order. Reactivities, injector-cup pressure drops, and ignition delays are compared and discussed.

NACA RM E56B21

EFFECT OF AMBIENT CONDITIONS ON THE PERFORMANCE OF A PRESSURE-JET POWERPLANT FOR A HELICOPTER. Richard P. Krebs. June 1956. 49p. diagrs. (NACA RM E56B21)

A generalized analysis of a pressure-jet powerplant was made. The effect of changes in ambient conditions on the powerplant performance is provided in a series of charts using parameters containing temperatures and pressures. Calculations were also made showing the effect of changes in ambient conditions on the hovering ceiling, hovering time, range, and rate of climb of a helicopter powered by a pressure-jet system.

NACA RM E56B27

TABLES AND CHARTS FOR THERMODYNAMIC CALCULATIONS INVOLVING AIR AND FUELS CONTAINING BORON, CARBON, HYDROGEN, AND OXYGEN. Eldon W. Hall and Richard J. Weber. July 1956. 82p. diagrs., tabs. (NACA RM E56B27)

Tables and charts of gas properties are presented for use in thermodynamic calculations for engine cycles involving the combustion of air and any fuel or combination of fuels containing carbon, boron, hydrogen, and oxygen. Dissociation and phase changes may be accounted for with the method presented, which does not require the presentation of separate data for each fuel-air ratio. Calculations are limited to stoichiometric or lesser fuel-air ratios. With boron-containing fuels, either equilibrium or frozen expansion may be assumed with respect to phase changes. Equations and examples are given illustrating calculations of combustion temperatures, expansion processes, and flow areas.

NACA RM E56B29

USE OF EFFECTIVE MOMENTUM THICKNESS IN DESCRIBING TURBINE ROTOR-BLADE LOSSES. Warner L. Stewart, Warren J. Whitney, and James W. Miser. May 1956. 26p. diagrs. (NACA RM E56B29)

The use of an effective rotor-blade momentum thickness in describing turbine rotor-blade losses is presented. Derivation of the necessary equations is presented for use in obtaining this momentum thickness for given overall turbine performance, stator performance, and rotor geometric quantities. Application is then made to a series of transonic turbine rotors to indicate the magnitude of the effective rotor-blade momentum thickness calculated for each of these rotors as well as the correlation obtained with a design rotor total surface diffusion parameter. A comparison of these results is made with the results calculated from previous low-speed two-dimensional cascade tests.

NACA RM E56D26

THERMAL DECOMPOSITION OF ETHYLPENTABORANE IN GAS PHASE. Glen E. McDonald. July 1956. 20p. diagrs., tab. (NACA RM E56D26)

The thermal decomposition of ethylpentaborane at temperatures of 185° to 244° C is approximately a 1.5-order reaction. The products of the decomposition were hydrogen, methane, a nonvolatile boron hydride, and traces of decaborane. Measurements of the rate of decomposition of pentaborane showed that ethylpentaborane has a greater rate of decomposition than pentaborane.

NACA RM E56F04

THEORETICAL PERFORMANCE OF JP-4 FUEL WITH A 70-30 MIXTURE OF FLUORINE AND OXYGEN AS A ROCKET PROPELLANT. II - EQUILIBRIUM COMPOSITION. Sanford Gordon and Vearl N. Huff. October 1956. 49p. diagrs., tabs. (NACA RM E56F04)

Data were calculated for equivalence ratios of 1 to 4, chamber pressures of 300 and 600 pounds per square inch absolute, and pressure ratios of 1 to 1500. Parameters included are specific impulse, combustion and exit temperatures, molecular weight, characteristic velocity, coefficient of thrust, ratio of nozzle-exit area to throat area, specific heat at constant pressure, isentropic exponent, viscosity, and thermal conductivity. A correlation is given which permits determination of performance for a wide range of chamber pressures. A method for obtaining specific impulse of JP-4 fuel with OF_2 and O_3-F_2 mixtures is given.

NACA RM L52B27

AERODYNAMIC LOADING CHARACTERISTICS OF A WING-FUSELAGE COMBINATION HAVING A WING OF 45° SWEEPBACK MEASURED IN THE LANGLEY 8-FOOT TRANSONIC TUNNEL. Donald L. Loving and Claude V. Williams. May 1952. 58p. diagrs., photos., tab. (NACA RM L52B27)

Results of an investigation of the loading over a wing-fuselage combination at transonic speeds are presented. The tests were made at Mach numbers from 0.94 to 1.13 for angles of attack of 4°, 8°, and 12°. Additional data were obtained for an angle of attack of 20° from a Mach number of 0.60 to 1.11. The Reynolds number of the investigation covered the range from 1.73×10^6 to 2.01×10^6. The wing had the quarter-chord line swept back 45°, an aspect ratio 4, taper ratio 0.6, and NACA 65A006 airfoil sections parallel to the airstream. Data are included from a previous investigation of the same wing-fuselage combination tested in the closed-throat test section at Mach numbers from 0.60 to 0.96 and at a Mach number of 1.2. Dynamic measurements of the wing-tip angle of twist are presented and compared with values calculated by utilizing the spanwise loadings in the moment-area method.

NACA RM L52E26

INVESTIGATION OF INTERFERENCE LIFT, DRAG, AND PITCHING MOMENT OF A SERIES OF RECTANGULAR WING AND BODY COMBINATIONS AT MACH NUMBERS OF 1.62, 1.93, AND 2.41. Donald E. Coletti. August 1952. 74p. diagrs., tabs. (NACA RM L52E26)

An investigation was made of a series of rectangular wing and body combinations at Mach numbers 1.62, 1.93, and 2.41 to determine the effects of aspect ratio, incidence angle, and forebody length on the interference lift, drag, and pitching moment. The angle-of-attack range was ±6°, and the Reynolds number range was from 0.33×10^6 to 1.40×10^6.

NACA RM L53A08

SOME APPROXIMATE METHODS FOR ESTIMATING THE EFFECTS OF AEROELASTIC BENDING OF ROCKET-PROPELLED MODEL-BOOSTER COMBINATIONS. Richard G. Arbic, George White, and Warren Gillespie, Jr. March 1953. 40p. diagrs., photos., tabs. (NACA RM L53A08)

Methods are presented for estimating the aeroelastic effects and structural requirements of rocket propelled model-booster combinations that are nearly symmetrical. Each method is presented according to its suitability for special types of model-booster configuration. The methods differ principally in the manner in which booster stiffness, reference axis, and inertia loading are considered, and permit estimation of the Mach number at which either a structural bending divergence or an aerodynamic pitching divergence of the combination may occur.

NACA RM L53B03

THE INFLUENCE OF A CHANGE IN BODY SHAPE ON THE EFFECTS OF TWIST AND CAMBER AS DETERMINED BY A TRANSONIC WIND-TUNNEL INVESTIGATION OF A 45° SWEPTBACK WING-FUSELAGE CONFIGURATION. Daniel E. Harrison. August 1953. 23p. diagrs., tab. (NACA RM L53B03)

An investigation has been made in the Langley 8-foot transonic tunnel to determine the influence of a body modification on the effects of twist and camber. The wing of the 45° sweptback wing-fuselage configuration was twisted and cambered to obtain a uniform load distribution at a Mach number of 1.2 and a lift coefficient of 0.4. The fuselage was modified in the region of the wing on the basis of the transonic drag-rise rule. Lift, drag, and pitching-moment results are presented at Mach numbers varying from 0.80 to 1.10 and Reynolds numbers varying from about 1.90×10^6 to 2.00×10^6 based on the mean aerodynamic chord.

NACA RM L54B09

THE EFFECT OF A CHANGE IN BODY SHAPE ON THE LOADING OF A 45° SWEPTBACK WING-BODY COMBINATION AT TRANSONIC SPEEDS. Donald L. Loving. April 1954. 67p. diagrs., photo. (NACA RM L54B09)

Transonic-tunnel pressure-distribution tests were made at Mach numbers from 0.60 to 1.13 of a wing-body configuration having a 45° sweptback wing of aspect ratio 4 on a fineness-ratio-11.8 body having an afterbody which was cylindrical from the region of the wing-body juncture rearward to the base. In order to demonstrate the effect of a change in body shape on the loading characteristics, comparisons are made with similar data obtained for the same wing on a fineness-ratio-10 body which was curved from the nose to the base. Results are presented for angles of attack of 0°, 4°, 8°, 12°, and 20°. The Reynolds numbers of the investigation covered the range from 1.74×10^6 to 2.03×10^6.

NACA RM L54B11

AERODYNAMIC CHARACTERISTICS OF A CRUCIFORM-WING MISSILE WITH CANARD CONTROL SURFACES AND OF SOME VERY SMALL SPAN WING-BODY MISSILES AT A MACH NUMBER OF 1.41. M. Leroy Spearman and Ross B. Robinson. April 1954. 27p. diagrs., tabs. (NACA RM L54B11)

An investigation has been made to determine the aerodynamic characteristics of a cruciform 70° delta-wing missile configuration with 70° delta canard control surfaces at $M = 1.41$ in the Langley 4- by 4-foot supersonic pressure tunnel. The complete model, various combinations of component parts, and modifications to the basic configuration were tested through an angle-of-attack range of 0° to about 28° at a sideslip angle of 0° and through an angle-of-sideslip range of 0° to about 20° at an angle of attack of 0°. Modifications to the configuration included variation of the body length and canard area and the substitution of a series of very small span wings for the cruciform delta wings and canard controls.

NACA RM L54B16

COMPARISON OF EXPERIMENTAL WITH CALCULATED RESULTS FOR THE LIFTING EFFECTIVENESS OF A FLEXIBLE 45° SWEPTBACK WING OF ASPECT RATIO 6.0 AT MACH NUMBERS FROM 0.8 TO 1.3. Richard E. Walters. April 1954. 35p. diagrs., photos., tab. (NACA RM L54B16)

Tests of the effective lift-curve slope of a flexible sweptback wing were made to evaluate the usefulness of the general methods used to predict the effective lift-curve-slope ratio. Wings of three degrees of flexibility were tested through a Mach number range of 0.8 to 1.3. The aspect-ratio-6.0, taper-ratio-0.6 wing which was tested had 45° sweep of the quarter-chord line and an NACA 65A009 streamwise airfoil section. The results from the tests show that the method used predicted values of the effective lift ratio which are within 5 percent of the experimental values.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L54B18

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF FINNED AND UNFINNED BODIES MOUNTED AT VARIOUS LOCATIONS FROM THE WINGS OF UNSWEPT, AND SWEPT-WING—FUSELAGE MODELS, INCLUDING MEASUREMENTS OF BODY LOADS. William J. Alford, Jr., and H. Norman Silvers. April 1954. 93p. diagrs., photos., tabs. (NACA RM L54B18)

Finned and unfinned ogive-cylinder bodies of fineness ratio 9.34 were tested in the Langley high-speed 7- by 10-foot tunnel on unswept- and swept-wing—fuselage models. The bodies, symmetrically located about the plane of symmetry, were suspended by pylons in the inboard location and also were mounted directly to the wing tip. Measurements were made of the forces and moments in pitch of the combined model and bodies, in addition to six-component force and moment measurements of the bodies in the presence of the models over a Mach number range of 0.50 to 0.91.

NACA RM L54B19

THE EFFECTS OF WING-MOUNTED EXTERNAL STORES ON THE TRIM, BUFFET, AND DRAG CHARACTERISTICS OF A ROCKET-PROPELLED MODEL HAVING A 45° SWEPTBACK WING. Allen B. Henning. April 1954. 25p. diagrs., photos., tabs. (NACA RM L54B19)

A rocket-propelled model has been flown to determine the effects of four wing-mounted bomb-type external stores on the trim, buffet, and drag characteristics of a wing-fuselage configuration having a 45° swept-back wing over a Mach number range of 0.7 to 1.4. The data are compared with data from a similar model without stores. Trim angle of attack, trim normal- and transverse-force coefficients, wing-tip helix angle, buffet intensities, and drag are plotted against Mach number.

NACA RM L54B23

PRESSURE RECOVERY AND DRAG CHARACTERISTICS OF A FORWARD LOCATED CIRCULAR SCOOP INLET AS DETERMINED FROM FLIGHT TESTS FOR MACH NUMBERS FROM 0.8 TO 1.6. Charles F. Merlet. April 1954. 23p. diagrs., photos., tab. (NACA RM L54B23)

A flight test was conducted on a circular scoop inlet located well forward on a parabolic body of revolution. Results are presented for a Mach number range of 0.8 to 1.6 at Reynolds numbers of 3×10^6 to 9×10^6, respectively, based on maximum body diameter, and a mass-flow-ratio range from 0.3 to 1.1. At maximum mass-flow ratio, the installation of the inlet caused only a small difference in drag as compared to the drag of the body alone. Total-pressure recoveries at the inlet-minimum-area station ranged from a value of 1.0 at subsonic speeds to a minimum value of 0.95 at $M = 1.6$.

NACA RM L55B10

LIFT, DRAG, AND LONGITUDINAL STABILITY AT MACH NUMBERS FROM 0.8 TO 2.1 OF A ROCKET-POWERED MODEL HAVING A TAPERED UNSWEPT WING OF ASPECT RATIO 3 AND INLINE TAIL SURFACES. Warren Gillespie, Jr. April 1955. 29p. diagrs., photo., tabs. (NACA RM L55B10)

A configuration having a body of fineness ratio 16.9, an unswept wing of aspect ratio 3 and taper ratio 0.4, and inline tail surfaces was aeropulsed continuously in pitch during free flight with and without a sustainer rocket motor operating. The Mach number range covered by the investigation was from 0.8 to 2.1. Zero-lift drag and drag-due-to-lift data were obtained during coasting flight of the model. Normal force, pitching moment, static longitudinal stability, and downwash and wake effects at the horizontal tail were obtained with and without the rocket motor thrusting.

NACA RM L55B11

COMPARISON OF THE STATIC STABILITY OF A 68.7° DELTA-WING MODEL WITH DIHEDRAL AND A TWISTED AND CAMBERED WING MODEL OF THE SAME PLAN FORM. John W. Paulson. April 1955. 18p. diagrs., tab. (NACA RM L55B11)

A force-test investigation at a Reynolds number of 440,000 of the static stability characteristics of a 68.7° delta-wing model with dihedral showed that, with vertical tail off or on, the model had large values of directional stability at high angles of attack with 20° and 30° of inboard dihedral.

NACA RM L55B15

EFFECTS OF A DETACHED TAB ON THE HINGE-MOMENT AND EFFECTIVENESS CHARACTERISTICS OF AN UNSWEPT TRAILING-EDGE CONTROL ON A 60° DELTA WING AT MACH NUMBERS FROM 0.75 TO 1.96. Odell A. Morris and Gertrude C. Westrick. April 1955. 36p. diagrs., photo. (NACA RM L55B15)

A wind-tunnel investigation has been made on a constant-chord trailing-edge control equipped with a detached tab on a 60° delta wing at Mach numbers from 0.75 to 1.96. Reynolds number of the test varied from 2.4×10^6 to 3.2×10^6. Rolling moment and lift effectiveness as well as hinge moments of the flap-tab combination were obtained for flap deflections of 0° to 15°, tab deflections of 0° to -15°, and angles of attack from 0° to ±12°.

LOW-SPEED MEASUREMENTS OF STATIC STABILITY, DAMPING IN YAW, AND DAMPING IN ROLL OF A DELTA, A SWEPT, AND AN UNSWEPT WING FOR ANGLES OF ATTACK FROM 0° TO 90°. Joseph L. Johnson, Jr. April 1956. 19p. diagrs., tabs. (NACA RM L56B01)

A low-speed investigation was conducted to determine the static stability, damping-in-yaw, and damping-in-roll derivatives of a 60° delta wing, a 45° swept wing of aspect ratio 2.61, and an unswept wing of aspect ratio 3 over an angle-of-attack range from 0° to 90°.

NACA RM L56B10

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE EFFECT OF HORIZONTAL-TAIL LOCATION ON LONGITUDINAL AND LATERAL STABILITY CHARACTERISTICS OF A COMPLETE MODEL HAVING A SWEPTBACK WING IN A HIGH LOCATION. H. Norman Silvers and Thomas J. King, Jr. April 1956. 46p. diagrs., tab. (NACA RM L56B10)

This paper presents results of an investigation made at high subsonic speeds to determine the static longitudinal and lateral stability characteristics of a complete model having four vertical locations of the horizontal tail and a sweptback wing located in a high position on the fuselage. The wing had 45° of sweepback, an aspect ratio of 4.0, taper ratio of 0.3, and NACA 65A006 airfoil sections. The results were obtained in the Langley high-speed 7- by 10-foot tunnel at Mach numbers from 0.80 to 0.92 and covered an angle-of-attack range from -2° to 23° and an angle-of-sideslip range from -4° to 12°.

NACA RM L56B14

EFFECTS OF REYNOLDS NUMBER AND LEADING-EDGE SHAPE ON THE LOW-SPEED LONGITUDINAL STABILITY OF A 6-PERCENT-THICK 45° SWEPTBACK WING. William C. Schneider. April 1956. 32p. diagrs. (NACA RM L56B14)

Force-test data showing the effects of changes in leading-edge radius on the longitudinal stability of a 6-percent-thick 45° sweptback wing of aspect ratio 3 are presented for several ranges of Reynolds number and Mach number. Data are presented for wings with NACA 0006-(4.76)3, NACA 0006-(6.74)3, and modified NACA 0006-(3.88)3 airfoil sections with leading-edge radii of 0.0025, 0.0050, and 0.0025 of the local wing chord parallel to the plane of symmetry, respectively, and for Reynolds numbers up to 6.6×10^6 and Mach numbers up to 0.20. This study is a continuation of the studies published in NACA RM L55F06, NACA RM L55H04, and NACA RM L55L30.

NACA RM L56B17

EXPLORATORY INVESTIGATION OF A HELICOPTER PRESSURE-JET SYSTEM ON THE LANGLEY HELICOPTER TEST TOWER. Robert A. Makofski and James P. Shivers. July 1956. 38p. diagrs., photo. (NACA RM L56B17)

An exploratory investigation of a helicopter pressure-jet system has been conducted on the Langley helicopter test tower. The effects of tip speed, fuel-air ratio, and pressure ratio on the propulsive characteristics of the pressure-jet system have been determined for a range of tip speeds from 442 to 559 feet per second, blade-root stagnation-pressure ratios of 1.9, 2.14, and 2.31, and fuel-air ratios from 0 to 0.03. A constant-area exit nozzle was used in the investigation. Without tip burning, a minimum overall specific fuel consumption of 2.28 pounds per hour per horsepower and a ratio of rotor propulsive horsepower to equivalent compressed-air horsepower of about 0.45 was obtained at a stagnation-pressure ratio of 2.31 and a tip speed of 558 feet per second. With burning at a fuel-air ratio of 0.02 at the tip unit, the overall specific fuel consumption was increased by about 11 percent and the power ratio was increased to about 1.0.

NACA RM L56B20

FREE-FLIGHT INVESTIGATION OF THE CONTROL EFFECTIVENESS OF A DIFFERENTIALLY DEFLECTED HORIZONTAL TAIL AT MACH NUMBERS FROM 0.8 TO 1.6. Jesse L. Mitchell and A. James Vitale. April 1956. 25p. diagrs., photo., tabs. (NACA RM L56B20)

A free-flight investigation has been made to determine the control effectiveness of a differentially deflected horizontal tail in the Mach number range from 0.8 to 1.6. The results of this investigation agreed in general with results of other investigations.

DECLASSIFIED NACA RESEARCH REPORTS

These results indicate that the rolling moment of the differentially deflected horizontal tail has relatively small variation with Mach number over the range of the test and that the yawing moment, in a direction usually referred to as favorable, is about two to three times as great as the rolling moment and has a comparatively large variation with Mach number.

NACA RM L56G18

BOUNDARIES OF SUPERSONIC AXISYMMETRIC FREE JETS. Eugene S. Love, Mildred J. Woodling, and Louise P. Lee. October 1956. 98p. diagrs. (NACA RM L56G18)

Calculations have been made by the method of characteristics of 2960 boundaries of supersonic axisymmetric free jets exhausting from conically divergent nozzles into still air. The calculations cover jet Mach numbers from 1.5 to 3.0, ratio of specific heats of the jet from 1.115 to 1.667, divergence angles of the nozzle from 5° to 20°, and jet static-pressure ratios from 1 to 10. The results are presented nondimensionally and in a form that facilitates practical use. Some random examples of the effects of the variables involved are shown, and the possibilities of the simulation of one jet by another are examined for jets exhausting into still air and into supersonic streams.

NACA RM L57E30

NOTES ON A LARGE-SCALE STATISTICAL PROGRAM FOR THE ESTABLISHMENT OF MANEUVER-LOADS DESIGN CRITERIA FOR MILITARY AIRPLANES. John P. Mayer, Ralph W. Stone, Jr., and Harold A. Hamer. July 1957. 57p. diagrs., tabs. (NACA RM L57E30)

An outline is presented of a statistical program to collect data for the establishment of more realistic maneuver-loads design criteria. Some details on the loads derivable from the measured quantities and the accuracy with which these loads may be obtained are discussed. In addition, some sample experimental data are used to indicate possible methods of statistical analysis for the assessment of maneuver-loads criteria and some remarks are made on the sample size required for the overall program. The methods used and the results possible from such a statistical program represent a goal which could be obtained under the assumptions made; however, many of the operations indicated in the outline for the statistical analysis are not known and will require further study. An actual program may differ in many respects to that presented, such differences depending in part upon the type and accuracy of the recording instrument selected.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1299

CORRELATION, EVALUATION, AND EXTENSION OF LINEARIZED THEORIES FOR TIRE MOTION AND WHEEL SHIMMY. Robert F. Smiley. 1957. v, 48p. diagrs., tab. (NACA Rept. 1299. Supersedes TN 3632)

An evaluation is made of the existing theories of linearized tire motion and wheel shimmy. It is demonstrated that most of the previously published theories represent varying degrees of approximation to a summary theory developed herein which is a minor modification of the basic theory of Von Schlippe and Dietrich. In most cases where strong differences exist between the previously published theories and the summary theory, it is shown that the previously published theories possess certain deficiencies. A series of systematic approximations to the summary theory is developed for the treatment of problems too simple to merit the use of the complete summary theory and procedures are discussed for applying the summary theory and its systematic approximations to the shimmy of more complex landing-gear structures than have previously been considered. Comparisons of the existing experimental data with the predictions of the summary and systematic approximation theories provide a fair substantiation of the higher approximate theories.

NACA Rept. 1307

LIFT AND CENTER OF PRESSURE OF WING-BODY-TAIL COMBINATIONS AT SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS. William C. Pitts, Jack N. Nielsen, and George E. Kaattari. 1957. ii, 70p. diagrs., tabs. (NACA Rept. 1307)

A method is presented for calculating the lift and centers of pressure of wing-body and wing-body-tail combinations at subsonic, transonic, and supersonic speeds. A set of design charts and a computing table are presented which reduce the computations to routine operations. Comparison between the estimated and experimental characteristics for a number of wing-body and wing-body-tail combinations shows correlation to within ±10 percent on lift and to within about ±0.02 of the body length on center of pressure.

NACA Rept. 1317

CLOUD-DROPLET INGESTION IN ENGINE INLETS WITH INLET VELOCITY RATIOS OF 1.0 AND 0.7. Rinaldo J. Brun. 1957. ii, 35p. diagrs., tab. (NACA Rept. 1317. Supersedes TN 3593)

The paths of cloud droplets into two engine inlets are calculated. The amount of water in droplet form ingested by the inlets and the amount and distribution of water impinging on the inlet walls are obtained from these droplet-trajectory calculations. In both types of inlet a prolate ellipsoid of revolution (10-percent thick) represents either part or all of the forebody at the center of an annular inlet to an engine. The configurations can also represent a fuselage of an airplane with side ram-scoop inlets. The principal difference between the two inlets studied is that the inlet air velocity of one is 0.7 that of the other.

NACA Rept. 1324

COMPARISON OF SEVERAL METHODS FOR OBTAINING THE TIME RESPONSE OF LINEAR SYSTEMS TO EITHER A UNIT IMPULSE OR ARBITRARY INPUT FROM FREQUENCY-RESPONSE DATA. James J. Donegan and Carl R. Huss. 1957. ii, 13p. diagrs., tabs. (NACA Rept. 1324. Supersedes TN 3701.)

The comparison indicates that all of the methods give good accuracy when applied to a second-order system; the main difference is the required computing time to obtain the same degree of accuracy. When applied to higher order systems, however, the methods generally classified as inverse Laplace transform methods were found most effective. Some discussion is given of the use of the methods as flight-data-analysis techniques in predicting loads and motions for a flexible aircraft when the aircraft frequency response is known.

NACA Rept. 1327

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE SUBSONIC-FLOW FIELDS BENEATH SWEPT AND UNSWEPT WINGS WITH TABLES OF VORTEX-INDUCED VELOCITIES. William J. Alford, Jr. 1957. ii, 43p. diagrs., photo., tabs. (NACA Rept. 1327. Supersedes TN 3738)

The flow characteristics around swept and unswept wings necessary in first-order estimations of aerodynamic loadings, trajectories, and jettison characteristics of missiles, fuel tanks, or bombs as determined experimentally are compared with the flow

CURRENT NACA RESEARCH REPORTS

fields as calculated by potential-flow theory. The theoretical predictions of the flow-field characteristics were qualitatively correct in all cases considered, although there were indications that the magnitude of the downwash angles tended to be overpredicted as the tip of the swept wing was approached and that the sidewash angles ahead of the unswept wing were underpredicted.

NACA Rept. 1328

A SECOND-ORDER SHOCK-EXPANSION METHOD APPLICABLE TO BODIES OF REVOLUTION NEAR ZERO LIFT. Clarence A. Syvertson and David H. Dennis. 1957. ii, 20p. diagrs., tabs. (NACA Rept. 1328. Supersedes TN 3527)

A second-order shock-expansion method applicable to bodies of revolution is developed by the use of the predictions of the generalized shock-expansion method in combination with characteristics theory. Equations defining the zero-lift pressure distributions and the normal-force and pitching-moment derivatives are derived. Comparisons with experimental results show that the method is applicable at values of the similarity parameter, the ratio of free-stream Mach number to nose fineness ratio, from about 0.4 to 2.

NACA Rept. 1330

EXPERIMENTAL AND PREDICTED LONGITUDINAL AND LATERAL-DIRECTIONAL RESPONSE CHARACTERISTICS OF A LARGE FLEXIBLE 35° SWEPT-WING AIRPLANE AT AN ALTITUDE OF 35,000 FEET. Henry A. Cole, Jr., Stuart C. Brown, and Euclid C. Holleman. 1957. ii, 39p. diagrs., photo., tabs. (NACA Rept. 1330. Supersedes RM A54H09; TN 3874)

Longitudinal and lateral-directional response to control surface motions are presented for a large flexible swept-wing airplane over a range of Mach numbers at 35,000 feet. Frequency responses, transfer functions, and stability derivatives are evaluated from transient response to elevator, aileron, and rudder inputs. Comparisons are made between response characteristics predicted for the rigid and flexible airplane, and those evaluated from transient flight data.

NACA Rept. 1334

RELATION OF TURBOJET AND RAMJET COMBUSTION EFFICIENCY TO SECOND-ORDER REACTION KINETICS AND FUNDAMENTAL FLAME SPEED. J. Howard Childs, Thaine W. Reynolds, and Charles C. Graves. 1957. ii, 13p. diagrs. (NACA Rept. 1334)

Theoretical studies of jet-engine combustion processes are summarized, and the equations are applied to experimental data. A parameter derived with the assumption that chemical reaction kinetics control the combustion rate correlates most turbojet combustion efficiencies. Another parameter derived with the assumption that flame spreading governs the combustion rate correlates ram-jet combustion efficiencies but is inadequate for the turbojet. Data indicate that a shift from one rate-controlling process to another occurs as combustor pressure is varied. The reaction-kinetics parameter best correlates the data at low pressures, whereas the flame-spreading parameter is better at higher pressures.

NACA Rept. 1335

MINIMUM WAVE DRAG FOR ARBITRARY ARRANGEMENTS OF WINGS AND BODIES. Robert T. Jones. 1957. ii, 6p. diagrs., photo. (NACA Rept. 1335. Supersedes TN 3530)

Studies of various arrangements of wings and bodies designed to provide favorable wave interference at supersonic speeds lead to the problem of determining the minimum possible value of the wave resistance obtainable by any disposition of the elements of an aircraft within given dimensions defined by a region. Under the assumptions that the total lift and the total volume of the aircraft are given, conditions that must be satisfied if the drag is to be a minimum are found. For arbitrary regions the minimum value can be estimated by a simple formula giving a lower bound.

NACA Rept. 1336

AN INVESTIGATION OF SINGLE- AND DUAL-ROTATION PROPELLERS AT POSITIVE AND NEGATIVE THRUST, AND IN COMBINATION WITH AN NACA 1-SERIES D-TYPE COWLING AT MACH NUMBERS UP TO 0.84. Robert M. Reynolds, Robert I. Sammonds, and John H. Walker. 1957. ii, 58p. diagrs., photos., tabs. (NACA Rept. 1336)

The results presented include propeller force characteristics, local velocity distributions in the propeller planes, inlet pressure recoveries, and static-pressure distributions on the cowling surfaces measured for a wide range of blade angles, advance ratios, and inlet-velocity ratios for the NACA 4-(5)(05)-041 four-blade, single-rotation propeller and the NACA 4-(5)(05)-037 six- and eight-blade, dual-rotation propellers in various combinations with NACA 1-series spinners, extended cylindrical spinners, and NACA D-type spinner cowlings.

NACA RM E57K12

PRELIMINARY STUDIES OF ROLLING-CONTACT FATIGUE LIFE OF HIGH-TEMPERATURE BEARING MATERIALS. Thomas L. Carter. April 1958. 27p. diagrs., tab. (NACA RM E57K12)

Preliminary studies of rolling-contact fatigue life of both races and balls of some promising high-temperature bearing materials were made at room temperature in the rolling-contact fatigue spin rig. The results may be of assistance in judging the relative potential of bearing steels for use at high temperatures. The following materials were investigaged: SAE 52100, MHT, TMT, MV-1, Halmo vacuum-melt, and AISI T-1, M-10, M-1, and M-50.

CURRENT NACA RESEARCH REPORTS

NACA RM E58A03a

DILUTION OF LIQUID OXYGEN WHEN NITROGEN IS USED FOR PRESSURIZATION. Thomas J. Walsh, R. R. Hibbard, and Paul M. Ordin. April 1958. 17p. diagrs. (NACA RM E58A03a)

A graphic method for determining the composition and phases existing within an oxygen propellant tank when pressurized with nitrogen gas is presented, and an example of the calculations involved is included. Adiabatic flow of the pressurizing gas from the pressure tank and the equilibrium state for the oxygen-nitrogen system are assumed as the limiting conditions. Enthalpy-concentration plots for the oxygen-nitrogen mixtures at constant pressures from 100 to 600 pounds per square inch absolute are presented. Both the equilibrium considerations and a small amount of experimental testing show that gaseous nitrogen may be unsuited for pressurizing liquid-oxygen systems.

NACA RM L58B05

LOW-SUBSONIC INVESTIGATION TO DETERMINE THE CHORDWISE PRESSURE DISTRIBUTION AND EFFECTIVENESS OF SPOILERS ON A THIN, LOW-ASPECT-RATIO, UNSWEPT, UNTAPERED, SEMI-SPAN WING AND ON THE WING WITH LEADING- AND TRAILING-EDGE FLAPS. Delwin R. Croom. April 1958. 133p. diagrs., tabs. (NACA RM L58B05)

Results are presented, without discussion, of a wind-tunnel investigation to determine the effect that spoilers at various spanwise and chordwise locations have on the lateral-control characteristics and the chordwise pressure distribution on a thin, untapered, unswept wing having an aspect ratio of 3.33 and NACA 65A004 airfoil sections. The wing was equipped with leading-edge and trailing-edge flaps.

NACA TM 1407

FREE CONVECTION UNDER THE CONDITIONS OF THE INTERNAL PROBLEM. (Svobodnaya convectzia v ousloviakh vnoutrennei zadachi.) G. A. Ostroumov. April 1958. vii, 233p. diagrs., photos., tabs. (NACA TM 1407. Translation of Russian Book, 1952)

This report attempts to fill the gap in scientific literature on convective processes in the gravitational-force field. Mathematical theory of steady and unsteady gravitational convection is presented. General nonlinear equations that can be linearized are emphasized. A discussion of the nonlinear theory is also presented. Experimental investigations of phenomena described by both the linear and nonlinear equations are considered, and experimental techniques are discussed. One chapter is concerned with the characteristics of water as the working fluid. Tabulated data are given on the thermal and convective parameters of water and are compared with those for other fluids.

NACA TM 1418

THE INTERACTION OF A REFLECTED SHOCK WAVE WITH THE BOUNDARY LAYER IN A SHOCK TUBE. Herman Mark, Cornell University. March 1958. ii, 128p. diagrs., photos., tabs. (NACA TM 1418)

By theoretical analysis the existence of several different types of interaction in different ranges of initial shock Mach number is predicted. This analysis is verified experimentally. The most complicated interaction is studied in detail, and a model is proposed. The features of the phenomenon are analyzed, based on this model, and are checked experimentally. The case of interaction with a turbulent boundary layer is also considered. A method is proposed whereby the effect of the laminar-boundary-layer interaction on the strength of the reflected shock may be calculated, and a comparison with experimental results is presented.

NACA TM 1433

STABILITY OF CYLINDRICAL AND CONICAL SHELLS OF CIRCULAR CROSS SECTION, WITH SIMULTANEOUS ACTION OF AXIAL COMPRESSION AND EXTERNAL NORMAL PRESSURE. (Ob ustoĭchivosti tsilindricheskikh i konicheskikh obolochek krugovogo cecheniia pri sovmestnom deĭstvii osevogo szhatiia i vneshnego normalnogo davleniia.) Kh. M. Mushtari and A. V. Sachenkov. April 1958. 15p. (NACA TM 1433. Translation from Prikladnaia Matematika i Mekhanika, v. 18, no. 6, November-December 1954, p. 667-674.)

The expressions for the upper limit of critical loads are presented for cylindrical and conical shells under the combined action of uniform compression and isotropic external normal pressure. The differential equations for neutral equilibrium are solved for conical shells with simply supported boundaries. These solutions are used to obtain approximate expressions for the determination of the critical external pressure with simultaneous longitudinal compression. Also included is a discussion of the accuracy of the approximate expressions.

NACA TM 1434

EXTREME SPEEDS AND THERMODYNAMIC STATES IN SUPERSONIC FLIGHT. (Extreme Geschwindigkeiten und thermische Zustände beim Überschallflug.) Klaus Oswatitsch. April 1958. 39p. diagrs., tabs. (NACA TM 1434. Translation from Zeitschrift für Flugwissenschaften, v. 4, no. 3/4, 1956, p. 95-108)

Typical of all cases of high-speed flow is the conversion of high kinetic energy into extreme thermodynamic states with temperatures of several thousand degrees; frequently, the gas is dissociated and ionized. A small sensitivity to high speeds is characteristic of gases of low molecular weight. With a minimum of mathematical and physical complexity, these matters are discussed in relation to meteors, shock tubes, ram jets, and rockets. The discussion is directed primarily to experts in neighboring fields and interested novices.

CURRENT NACA RESEARCH REPORTS

NACA TN 4140

TURBULENT SHEARING STRESS IN THE BOUNDARY LAYER OF YAWED FLAT PLATES. Harry Ashkenas, Cornell University. April 1958. 58p. diagrs., photos., tab. (NACA TN 4140)

Hot-wire anemometer measurements of the turbulent shearing stress in a turbulent boundary layer on a yawed flat plate are presented. Two plates with angles of yaw of 0° and 45° were studied. Measurements of the intensity of turbulence were made simultaneously with the shear measurements, using a technique developed by the author. The experimental procedure is reviewed briefly and an attempt is made to evaluate the precision of the results.

NACA TN 4150

APPROXIMATIONS FOR THE THERMODYNAMIC AND TRANSPORT PROPERTIES OF HIGH-TEMPERATURE AIR. C. Frederick Hansen. March 1958. 67p. diagrs., tabs. (NACA TN 4150)

Approximations are presented for the thermodynamic and transport properties of high-temperature air. Compressibility, energy, entropy, the specific heats, the speed of sound, the coefficients of viscosity and thermal conductivity, and the Prandtl number for air are tabulated from 500° to $15,000^{\circ}$ K over a range of pressures from 0.0001 to 100 atmospheres.

NACA TN 4206

MEASUREMENTS OF TOTAL HEMISPHERICAL EMISSIVITY OF VARIOUS OXIDIZED METALS AT HIGH TEMPERATURE. William R. Wade. March 1958. 43p. diagrs., photos. (NACA TN 4206)

The results of measurements of total hemispherical emissivity over the temperature range of 600° to $2,000^{\circ}$ F for various heavily oxidized metals are presented, together with a description of the equipment and the procedures used. The variation of total emissivity due to oxidation of the materials is presented, up to the highest temperature which produces an adherent oxide coating. Results from investigations to determine any deviation of the thermal radiation from Lambert's cosine law for the oxidized metals are presented.

NACA TN 4207

EFFECT OF A STRINGER ON THE STRESS CONCENTRATION DUE TO A CRACK IN A THIN SHEET. J. Lyell Sanders, Jr. March 1958. 19p. diagrs., tab. (NACA TN 4207)

A coefficient is obtained for determining the effect of a reinforcing stringer on the stress concentration factor at the tip of a crack in a thin sheet. The results are given for the case in which the stringer is intact and for the case in which the stringer is broken. In the first case the stress concentration factor for the stringer is also given.

NACA TN 4212

CENTRAL AUTOMATIC DATA PROCESSING SYSTEM. By the Staff of the Lewis Laboratory. Chapter I: GENERAL DESCRIPTION. Bert A. Coss. Chapter II: CENTRAL RECORDING SYSTEM. Robert L. Miller. Chapter III: AUTOMATIC VOLTAGE DIGITIZERS. Leonard Jaffe and Richard L. Smith. Chapter IV: FREQUENCY DATA. John Ryskamp. Chapter V: DIGITAL AUTOMATIC MULTIPLE PRESSURE RECORDER. Leonard Jaffe, Arthur J. Gedeon, and Richard N. Bell. Chapter VI: PLAYBACK AND CONTROL ROOM EQUIPMENT. John Ryskamp. April 1958. (iii), 96p. diagrs., photos. (NACA TN 4212)

A centralized system has been developed and installed for the automatic recording and processing of data from several remotely located testing stations. Pressures, voltages, frequencies, and other pertinent variables are recorded on magnetic tape in digital form. The magnetic tape is fed into a high-speed digital computer to convert raw data to dimensioned quantities and to compute any terminal calculations called for by the test engineer. Computed data can be returned to the test engineer the next day; raw data can be returned immediately. The system has been in operation for 2 years.

NACA TN 4215

APPLICATION OF A HIGH-TEMPERATURE STATIC STRAIN GAGE TO THE MEASUREMENT OF THERMAL STRESSES IN A TURBINE STATOR VANE. R. H. Kemp, C. R. Morse, and M. H. Hirschberg. March 1958. 36p. diagrs., photos., tab. (NACA TN 4215)

Static high-temperature resistance-wire strain gages were used to measure the thermal stresses in a turbine stator vane that was subjected to a temperature variation simulating engine operating conditions. Stresses of -18,000 and -27,000 psi were measured in the leading and trailing edges, respectively. The measured values, in general, compared favorably with analytically determined stresses.

NACA TN 4217

EFFECT OF JET TEMPERATURE ON JET-NOISE GENERATION. Vern G. Rollin. March 1958. 13p. diagrs., photo. (NACA TN 4217)

Sound measurements were made on a 9/16-inch-model air jet over a range of pressure ratios from 1.3 to 1.9 and jet-air temperatures from 80° to 1000° F. Results indicated that sound power can be adequately predicted by the Lighthill parameter based on ambient temperature over the range of temperatures investigated.

CURRENT NACA RESEARCH REPORTS

NACA TN 4218

ANALYSIS OF STRESSES AND DEFLECTIONS IN A DISK SUBJECTED TO GYROSCOPIC FORCES. M. H. Hirschberg and A. Mendelson. March 1958. 37p. diagrs. (NACA TN 4218)

The differential equations governing the stresses and deflections of a disk of variable thickness subjected to gyroscopic loading are derived. For a disk of constant thickness, solutions are obtained by a finite-difference method for a wide range of disk geometry and loading.

NACA TN 4219

PROPELLANT VAPORIZATION AS A CRITERION FOR ROCKET ENGINE DESIGN; RELATION BETWEEN PERCENTAGE OF PROPELLANT VAPORIZED AND ENGINE PERFORMANCE. Marcus F. Heidmann and Richard J. Priem. March 1958. 19p. diagrs. (NACA TN 4219)

A method is presented for evaluating experimental rocket-engine performance in terms of the percentage of liquid propellant vaporized. The method is based on a hypothesis that rocket performance is limited by the rate of vaporization of the propellants. An expression relating characteristic exhaust velocity to the percentages of oxidant and fuel vaporized and burned is given. The analysis is applied to the hydrogen-fluorine, hydrogen-oxygen, ammonia-fluorine, and JP-4 - oxygen propellant combinations.

NACA TN 4220

A FLIGHT EVALUATION AND ANALYSIS OF THE EFFECT OF ICING CONDITIONS ON THE ZPG-2 AIRSHIP. William Lewis and Porter J. Perkins, Jr. April 1958. 66p. diagrs., photos., tab. (NACA TN 4220)

Test flights conducted by the U. S. Navy in a number of typical icing conditions are described. The airship operated successfully in all icing conditions encountered, but the desirability of limited protection for certain components was indicated. Icing in clouds was confined to wires and small components, but freezing rain and drizzle produced some icing on the envelope also. Theoretical calculations are presented which suggest that, while hazardous icing in freezing rain can occur under certain meteorological conditions, the probability of encountering these conditions is very small in coastal areas and approaches zero 200 to 300 miles offshore.

NACA TN 4222

DROP-SIZE DISTRIBUTIONS FOR IMPINGING-JET BREAKUP IN AIRSTREAMS SIMULATING THE VELOCITY CONDITIONS IN ROCKET COMBUSTORS. Robert D. Ingebo. March 1958. 23p. diagrs., photos., tab. (NACA TN 4222)

Data obtained with a high-speed camera were analyzed by using the Nukiyama-Tanasawa expression $dR/dD = (3.915/D_{30})^6(D^5/120)\exp[-3.915\ D/D_{30}]$, where R is the volume fraction of drops having diameters < D, and D_{30} is the volume-number-mean drop diameter. A range of orifice diameters (D_j = 0.029, 0.060, and 0.089 in.), liquid-jet velocities (V_j = 30, 65, and 100 ft/sec), and velocity differences between the airstream and the liquid jets (ΔV = 0 to 235 ft/sec) gave maximum-observed drop diameters ranging from 180 to 1160 microns. Values of D_{30} varied from 68 to 347 microns, and the following empirical expression was derived: $D_j/D_{30} = 2.64\sqrt{D_jV_j} + 0.97\ D_j\Delta V$, where diameters are expressed in inches and velocities in feet per second.

NACA TN 4223

RELATION OF JOURNAL BEARING PERFORMANCE TO MINIMUM OIL-FILM THICKNESS. F. W. Ocvirk and G. B. DuBois, Cornell University. April 1958. 48p. diagrs., tab. (NACA TN 4223)

The minimum thickness of the oil film is used as a basic variable in performance curves of plain journal bearings under a steady load. Analytical curves based on the short-bearing approximation and the solution of Cameron and Wood are compared with various experimental data. Load capacity and predicted film thickness at friction-curve hook points are correlated with peak-to-valley surface roughnesses. Analytical curves show the effect of bearing-clearance changes on friction power loss, film thickness, and peak pressure in the oil film.

NACA TN 4224

EFFECT OF OVERHEATING ON CREEP-RUPTURE PROPERTIES OF M-252 ALLOY. John P. Rowe and J. W. Freeman, University of Michigan. March 1958. 83p. diagrs., photos., tabs. (NACA TN 4224)

The effects of overheats to temperatures of 1,650°, 1,800°, 1,900°, and 2,000° F were evaluated in terms of the changes in creep-rupture properties at 1,500° F of M-252 alloy under stresses within the range of rupture strengths of the alloy for 80 to 1,000 hours. Overheat periods were predominantly of 2-minute duration and were applied cyclically at approximately 5- or 12-hour intervals. The results are compared with results of similar tests on S-816 and HS-31 alloys.

CURRENT NACA RESEARCH REPORTS

NACA TN 4229

STAGNATION-POINT HEAT TRANSFER TO BLUNT SHAPES IN HYPERSONIC FLIGHT, INCLUDING EFFECTS OF YAW. A. J. Eggers, Jr., C. Frederick Hansen, and Bernard E. Cunningham. April 1958. 54p. diagr. (NACA TN 4229)

An approximate theory is developed for the heat flux to the stagnation region of blunt bodies in hypersonic flight. The theory is found to agree with available experimental results including real gas effects such as dissociation. The effect of yaw on heat transfer to a cylindrical stagnation region is treated, and it is predicted that large yaw should cause sizable reductions in the heat-transfer rate.

NACA TN 4230

PRANDTL-MEYER EXPANSION OF CHEMICALLY REACTING GASES IN LOCAL CHEMICAL AND THERMODYNAMIC EQUILIBRIUM. Steve P. Heims. March 1958. 17p. diagrs. (NACA TN 4230)

It is shown how Prandtl-Meyer flow, in which chemical reactions are occurring and are in equilibrium, can be simply and exactly calculated. The property of air which governs the flow is found to be a quantity which depends only on the ratio of enthalpy to the square of the speed of sound; the analogous quantity for an inert gas depends only on the ratio of specific heats. A numerical example is given.

NACA TN 4231

SKIN-FRICTION MEASUREMENTS IN INCOMPRESSIBLE FLOW. Donald W. Smith and John H. Walker. March 1958. 67p. diagrs., photo., tabs. (NACA TN 4231)

Experiments have been conducted to measure the local surface-shear stress and the average skin-friction coefficient in incompressible flow for a turbulent boundary layer on a smooth flat plate having zero pressure gradient. Data were obtained for a range of Reynolds numbers from 1 million to 45 million. The local surface-shear stress was measured by a floating-element skin-friction balance and also by a calibrated total head tube located on the surface of the test wall. The average skin-friction coefficient was obtained from boundary-layer velocity profiles.

NACA TN 4232

A METHOD FOR THE CALCULATION OF WAVE DRAG ON SUPERSONIC-EDGED WINGS AND BIPLANES. Harvard Lomax and Loma Sluder. March 1958. 24p. (NACA TN 4232)

A method is presented for finding the lift, moment, and drag on three-dimensional wings or biplanes with supersonic edges and a straight trailing edge normal to the free stream. The minimum wave drag for fixed lift or volume is given for several special cases. Simple applications of the method may provide some measure of the degree to which more abstract methods for finding minimums can be relied upon as a measure of optimum real systems.

NACA TN 4233

EXPERIMENTAL STUDY OF THE EQUIVALENCE OF TRANSONIC FLOW ABOUT SLENDER CONE-CYLINDERS OF CIRCULAR AND ELLIPTIC CROSS SECTION. William A. Page. April 1958. 45p. diagrs., photos., tab. (NACA TN 4233)

An experimental investigation at transonic speeds of the pressures on a flat, winglike, elliptic cone cylinder and its equivalent body, a circular cone cylinder, provides confirming evidence of the equivalence relationships theoretically predicted by transonic slender-body theory.

NACA TN 4234

PRESSURE DISTRIBUTIONS AT TRANSONIC SPEEDS FOR PARABOLIC-ARC BODIES OF REVOLUTION HAVING FINENESS RATIOS OF 10, 12, AND 14. Robert A. Taylor and John B. McDevitt. March 1958. 80p. diagrs., photo. (NACA TN 4234)

The measured static-pressure distributions at the model surface and in the surrounding flow field are presented for the bodies at zero angle of attack. The Mach number range extended from 0.80 to 1.20 and the Reynolds number range was 23.4×10^6 to 28.6×10^6 (based on the theoretical length of the model).

NACA TN 4236

EFFECTS OF MACH NUMBER AND WALL-TEMPERATURE RATIO ON TURBULENT HEAT TRANSFER AT MACH NUMBERS FROM 3 TO 5. Thorval Tendeland. April 1958. 46p. diagrs. (NACA TN 4236)

Heat-transfer data were evaluated from temperature time histories measured on a cooled cone-cylinder model with turbulent flow at Mach numbers 3.00, 3.44, 4.08, 4.56, and 5.04. The effects of Mach number and wall-temperature ratio on Stanton number are compared with predictions from existing theories. The data were correlated by the T' method which has been used to correlate turbulent skin-friction data.

NACA TN 4239

EXPERIMENTAL INVESTIGATION OF THE DRAG OF FLAT PLATES AND CYLINDERS IN THE SLIPSTREAM OF A HOVERING ROTOR. John W. McKee and Rodger L. Naeseth. April 1958. 42p. diagrs., photos., tab. (NACA TN 4239)

An experimental study has been made of the drag of flat plates and cylinders in the slipstream of a rotor for the condition of hovering away from the effect of the ground. Random fluctuations and a very nonuniform average radial distribution of dynamic pressure

CURRENT NACA RESEARCH REPORTS

existed in the slipstream. The drag of constant-chord models spanning the rotor disk was relatively unaffected by distance from the plane of the rotor. An attempt to compare model drag coefficients with values obtained from wind-tunnel tests led to rather inconclusive results, particularly for the cylinders.

NACA TN 4249

A THEORETICAL ANALYSIS OF THE EFFECT OF ENGINE ANGULAR MOMENTUM ON LONGITUDINAL AND DIRECTIONAL STABILITY IN STEADY ROLLING MANEUVERS. Ordway B. Gates, Jr., and C. H. Woodling. April 1958. 20p. diagrs., tab. (NACA TN 4249. Supersedes RM L55G05)

The effect of engine momentum on the longitudinal and directional stability of aircraft in steady rolling maneuvers has been investigated. The results presented indicate that the gyroscopic moments produced on the aircraft by the rotating engine in rolling maneuvers can have an appreciable effect on the range of rolling velocities for which longitudinal or directional instability might occur.

NACA TN 4260

GROUND REFLECTION OF JET NOISE. Walton L. Howes. April 1958. 56p. diagrs., photo. (NACA TN 4260)

The effect of a reflecting plane is determined from theory and experiment. From the theoretical characteristics of far-field acoustic decay a correction-to-free-field procedure is developed for data obtained in the presence of a plane. Measurements of jet noise indicated the practical significance of reflections. Several theoretical predictions were confirmed from experimental decay curves and corrected spectra.

NACA TN 4262

ANALYSIS OF TURBULENT FLOW AND HEAT TRANSFER ON A FLAT PLATE AT HIGH MACH NUMBERS WITH VARIABLE FLUID PROPERTIES. R. G. Deissler and A. L. Loeffler, Jr. April 1958. 61p. diagrs. (NACA TN 4262)

A previous analysis of turbulent heat transfer and flow with variable fluid properties in smooth passages is extended to flow over a flat plate at high Mach numbers, and the results are compared with experimental data. Velocity and temperature distributions are calculated for a boundary layer with appreciable effects of frictional heating and external heat transfer. Viscosity and thermal conductivity are assumed to vary as a power of the temperature, while Prandtl number and specific heat are taken as constant. Skin-friction and heat-transfer coefficients are calculated and compared with incompressible values. The rate of boundary-layer growth is obtained for various Mach numbers.

AN EXPERIMENTAL INVESTIGATION OF THE EFFECT OF ENGINE LOADS ON WING STRUCTURES. J. L. Reddaway. 1957. 15p. diagrs., photo. ARC R & M 3062; ARC 13,309. Supersedes RAE Structures 64. (Ask for N-1597X*)

Three cellulose-nitrate model wings, identical except for rib flexibility, have been tested under conditions reproducing typical engine loads. Stress distributions have been found experimentally by means of electrical resistance strain gages. The distribution due to an abrupt change of torsion has been compared with a theory by Williams, and that due to an abrupt change of shear with a theory by Taylor. Local stresses at the engine nacelle are found to be appreciably higher in practice than would have been predicted by either of these theories. The discrepancies, moreover, are found to increase with rib flexibility.

GUST ALLEVIATION FACTOR. PARTS I, II, AND III. J. K. Zbrozek. 1958. 50p. diagrs., tabs. ARC R & M 2970; ARC 14,319. Supersedes RAE Aero 2421. (Ask for N-11238X*)

The report presents the theoretical calculations of gust alleviation factor made for rigid aircraft and with one degree of freedom only (that is, vertical motion). It is shown that for average gust lengths and for orthodox (tailed) aircraft the influence of the second degree of freedom (that is, pitching) on the value of the gust alleviation factor is negligibly small, providing the pitching moment of inertia and damping are not unduly small. The influence of aspect ratio, the importance of the mass parameter, and the gust shape on the values of the gust alleviation factor are shown.

THEORETICAL LOAD DISTRIBUTION ON A WING WITH A CYLINDRICAL BODY AT ONE END. J. Weber. 1957. 18p. diagrs. ARC R & M 2889; ARC 18,413. Supersedes RAE Aero 2467.
(Ask for N-17505X*)

A method is derived for calculating the spanwise load distribution over a lifting wing having a long circular-cylindrical body at one end. The solution is derived for arrangements giving constant induced downwash, but can be generalized to obtain approximate results for other plan forms including those with sweepback. Charts are given for the case in which the sectional lift slope is constant along the span. The lift distribution over both wing and body can be determined quickly, or the overall load obtained directly. The results are applicable to the determination of side forces on a fin in combination with the rear fuselage of an aircraft, or of the lift loading on a wing with a weapon or fuel tank at one tip.

TESTS IN THE ROYAL AIRCRAFT ESTABLISHMENT 10-FT X 7-FT HIGH-SPEED TUNNEL ON 50-DEG SWEPT-BACK WINGS. PART I. THREE OF 7.5 PER CENT THICKNESS. PART II. ONE OF 7.5 PER CENT THICKNESS WITH STALL FENCES AND LEADING-EDGE CHORD EXTENSION. A. B. Haines and C. W. Rhodes. 1957. 84p. diagrs., photos., tabs. ARC R & M 3043; ARC 17,414. Supersedes RAE Aero 2522 and RAE Aero 2521.
(Ask for N-34848Y*)

Two wings had sections of RAE 101 shape (maximum thickness at 0.31c) and differed principally in aspect ratio (3.1 and 3.5). The third wing had an aspect ratio of about 3.1 but a different section shape with its maximum thickness further aft at 0.4c and, as shown by the results of the tests, an effectively sharper nose than for the RAE 101 shape. Lift, drag, pitching moment, and root bending moment were measured over the range $M = 0.50$ to about 0.95 at a Reynolds number of about 2×10^6 for all three wings, and for the two smaller aspect-ratio wings for three Reynolds numbers up to about 6×10^6 at $M = 0.2$. Flow patterns were investigated by an oil-film technique and with surface tufts.

Aeronautical Research Council (Gt. Brit.)
THE USE OF PITOT-TUBES IN THE MEASUREMENT OF LAMINAR BOUNDARY LAYERS IN SUPERSONIC FLOW. R. J. Monaghan. 1957. 24p. diagrs., photos., tabs. ARC R & M 3056; ARC 17,896. Supersedes RAE Tech. Note Aero 2369.
(Ask for N-38124X*)

Consideration of experimental results obtained with relatively large pitot tubes in relatively thin laminar boundary layers on cones and flat plates in supersonic wind tunnels and then analyzed using standard pitot equations, shows that the most noticeable distortion of the velocity profile is the appearance of a peak near the outer edge of the boundary layer. The displacement of the main body of the profile, familiar in incompressible-flow tests, may be small in supersonic flow and difficult to detect when making measurements with small-diameter pitot tubes.

FLIGHT EXPERIMENTS ON BOUNDARY-LAYER CONTROL FOR LOW DRAG. M. R. Head, D. Johnson, and M. Coxon. 1957. 29p. diagrs., photos., tabs. ARC R & M 3025; ARC 17,780. Supersedes RAE Aero 2541. (Ask for N-38562X*)

Tests have been made with distributed suction applied to a short-span sleeve fitted to the upper surface of the wing of a single-seat Vampire aircraft. Full-chord laminar flow was maintained up to RN in the region of 29 million and Mach number up to 0.70, which was very nearly the critical Mach number of the sleeve section. The suction quantities required were sufficiently small to result in overall reductions in profile drag of between 70 and 80 percent, account being taken of the power required for suction. Difficulties were experienced due to surface roughness, and although these are believed to have resulted largely from the particular type of porous covering used in the tests, the problem of maintaining a sufficiently smooth and clean surface is evidently of crucial importance to full-scale application.

MEASUREMENTS OF TWO-DIMENSIONAL DERIVATIVES ON A WING-AILERON-TAB SYSTEM WITH A 1541 SECTION AEROFOIL. PART II - DIRECT TAB AND CROSS AILERON-TAB DERIVATIVES. K. C. Wight, National Physical Laboratory. 1958. 28p. diagrs., tabs. ARC R & M 3029; ARC 17,437. (Ask for N-40083, pt. 2*)

Measurements have been made for a 1541 section two-dimensional airfoil (N.P.L. 282) with a 20-percent aileron and 4-percent (approx.) tab. In addition some measurements of the direct aileron derivatives have been made for comparison with earlier results together with a number of static derivatives for the wing and controls. The influence is shown of frequency parameter, Reynolds number, position of transition, mean tab angle, and sealing of the control hinge gaps. Some tests have been made with the aileron set at -8° and the tab at $+12^{\circ}$ for which condition the hinge moment on the aileron was zero.

THE POLYMERISATION OF PHOSPHONITRILIC CHLORIDES. PART III. THE EFFECT OF WATER ON POLYPHOSPHONITRILIC CHLORIDE. F. G. R. Gimblett. November 1957. 13p. diagrs., tabs. RAE Tech. Note Chem. 1322. (Ask for N-42806, pt. 3*)

The influence of water on polyphosphonitrilic chloride has been studied at 25° C and 30° C. The results show that the polymer is rapidly attacked by water, being completely decomposed in 4 to 5 days. The decomposition is brought about essentially by the interchange of chloride and hydroxyl ions between the water and polymer, and its rate is influenced by the temperature, and the gel fraction of the polymer. Some considerations concerning the polymeric gel fraction are discussed.

A METHOD FOR CALCULATING THE PRESSURE DISTRIBUTION OVER JET-FLAPPED WINGS. D. Küchemann. 1957. 25p. diagrs. ARC R & M 3036; ARC 18,474. Supersedes RAE Aero 2573. (Ask for N-44914X*)

The incompressible flow past an airfoil with a thin jet emerging from its lower surface somewhere near the trailing edge is considered. Based on work of Gates, Maskell, and Spence, a simple method is described for calculating the pressure distribution over wings of nonzero thickness. The effects of finite aspect ratio and of camber are included and the method can be used for design purposes. The possible effects of sweep are briefly discussed. It is pointed out that a saddleback chordwise loading is typical for airfoils with jets and that this is the basic reason for most of the aerodynamic advantages of the jet-flap system.

THE EFFECT ON WEATHER MINIMA OF APPROACH SPEED, COCKPIT CUT-OFF ANGLE AND TYPE OF APPROACH COUPLER FOR A GIVEN LANDING SUCCESS RATE AND LEVEL OF SAFETY. E. S. Calvert and J. W. Sparke. 1958. 21p. diagrs. ARC CP 378. (Ask for N-48652X*)

This note attempts to make a realistic assessment of the performance of various approach couplers using the results of some tests made during the past 2 years, both full scale and on a landing simulator. The influence of cockpit cut-off angle, approach speed, ground lighting pattern, and runway width on the weather which can be defeated by a coupler of given accuracy is discussed. One important result of the simulator tests is that in marginal weather visual guidance in the vertical plane may be defective at heights above 100 feet. The implications of this on the cockpit and G.C.A. procedures are pointed out, and some suggestions are made for improving safety.

N-48789X*

Aeronautical Research Council (Gt. Brit.)
THE EFFECT OF INLET CIRCUMFERENTIAL MALDISTRIBUTION ON AN AXIAL COMPRESSOR STAGE. R. C. Turner, J. Ritchie, and C. E. Moss. 1958. 16p. diagrs. ARC R & M 3066; ARC 19,047. Supersedes NGTE R.203. (Ask for N-48789X*)

This report describes tests on a single compressor stage with circumferentially nonuniform inlet conditions. The stage was a model of the first stage of a typical modern aircraft-engine compressor, and the tests were planned as part of an investigation into the surge behavior of compressors with inlet flow maldistribution. It was found that with a roughly rectangular inlet velocity distribution of amplitude ±25 percent of the mean value, the surge flow instead of showing an expected increase was almost unchanged, being in fact slightly reduced. The efficiency fell greatly, with an accompanying small drop in temperature-rise coefficient. The velocity profile was distorted and its amplitude greatly decreased at the outlet of the stage.

THE ACCURACY OF MEASUREMENT OF TURBULENT SKIN FRICTION BY MEANS OF SURFACE PITOT-TUBES AND THE DISTRIBUTION OF SKIN FRICTION ON A FLAT PLATE. R. A. Dutton, University of Cambridge. 1957. 18p. diagrs. ARC R & M 3058; ARC 18,658. (Ask for N-58770*)

An experimental study has been made of two-dimensional turbulent boundary-layer flow with zero pressure gradient. The investigation was made to determine the accuracy of a method proposed by Preston for measuring the local turbulent skin friction. The general momentum equation was used in conjunction with measurements of skin friction by Preston's method, to obtain increments in momentum thickness which could be compared with the measured values. The experiments were made on a smooth flat plate, 6 feet long, which spanned the working section of a return-circuit wind tunnel. Transition was promoted by trip wires and glass-paper strips. A constant Reynolds number of 3.9×10^5 per foot was maintained throughout the experiments.

Royal Aircraft Establishment (Gt. Brit.)
REAL GAS EFFECTS ON SHOCK-TUBE PERFORMANCE AT HIGH SHOCK STRENGTHS. J. L. Stollery, Imperial College. November 1957. 24p. diagrs. RAE Tech.Note Aero 2413. (Ask for N-59111*)

Calculations have been made to find the flow conditions behind shock waves in argon-free air of strengths $M_S = U/a_1$ up to about 35. The tables used are based on the currently accepted value for the dissociation energy of nitrogen of 9.758 e.v. per molecule, and are for equilibrium conditions. Two cases only have been considered, namely:

(1) $P_1 = \frac{1}{10}$ atm, $T_1 = 290^\circ$ K

(2) $P_1 = \frac{1}{100}$ atm, $T_1 = 290^\circ$ K

The driving conditions needed to produce such strong shocks have been calculated assuming "ideal" hydrogen ($\gamma = 1.41$) to be the driving gas. In conclusion, the test conditions available through expanding the flow behind the shock are presented for an expansion ratio of 225 and the question of flight simulation is discussed.

National Gas Turbine Establishment (Gt. Brit.)
SOME TESTS ON CASCADES OF COMPRESSOR BLADES FITTED WITH VORTEX GENERATORS. R. Staniforth. January 1958. 18p. diagrs., photos. NGTE Memorandum M.314. (Ask for N-59116*)

Cascade tests showed that the fitting of vortex generators to the convex surface of compressor blades increased the two-dimensional losses under all conditions. A more detailed investigation indicated that the vortex generators were, in fact, suppressing shock-induced flow separation, but that boundary-layer separation still occurred at about 50 percent chord - probably due to the increased boundary-layer thickness produced by the vortex generator drag. While there is always a possibility that some different configuration will be successful, the scheme of increasing the drag critical Mach number of a compressor cascade by means of vortex generators is, on the basis of available test evidence, a failure.

Aeronautical Research Council (Gt. Brit.)
A RAPIDLY CONVERGENT PROCESS FOR SOLVING THE EQUATIONS OF SUBSONIC FLOW. I. TWO-DIMENSIONAL FLOW. A. B. Tayler, Mathematical Institute. August 14, 1957. 41p. diagrs., tabs.
ARC 19,470; FM 2573. (Ask for N-59122, pt. 1*)

The irrotational inviscid compressible equations for the flow of a perfect gas have been transformed into a symmetrical form by introducing new variables $\underline{s} = \left(\frac{\rho}{\rho_0}\right)^{\frac{1}{2}} \frac{q}{a_0}$ and $\sigma = \frac{1}{2} \log_e \frac{\rho_0}{\rho}$. Bernoulli's equation then becomes a relationship between $|\underline{s}|^2$ and σ which is independent of initial conditions. Results are given for a circular cylinder without circulation at $M_\infty = 0.4$.

N-59531*

Aeronautical Research Council (Gt. Brit.)
TESTS ON A TWO-DIMENSIONAL SLOTTED-WALL WIND TUNNEL WITH LATERAL OBSTRUCTIONS BEHIND THE SLOTS. A. Chinneck, C. J. Berry, and P. J. Peggs, National Physical Laboratory. 1958. 28p. diagrs., photos. ARC CP 372.
(Ask for N-59531*)

Tests have been made with lateral strips fixed to the back of the slotted walls of the N.P.L. 9- by 3-inch high-speed wind tunnel to find whether such strips would have a serious effect on the flow. The strips gave rise to shock waves at the beginning of the slotted section at supersonic speeds but the strength of these shock waves could be greatly reduced by displacing the strips a small distance from the wall. Observations of the flow round a two-dimensional 10-percent-thick RAE 104 airfoil showed that the strips had an effect similar to that of reducing the ratio of open to total area.

A NUMERICAL METHOD FOR CALCULATING THE STARTING AND PERTURBATION OF A TWO-DIMENSIONAL JET AT LOW REYNOLDS NUMBER. R. B. Payne, University of Manchester. 1958. 50p. diagrs. ARC R & M 3047; ARC 18,846.
(Ask for N-59532*)

There is a great need for a method of attacking directly the full equations of motion of an unsteady viscous flow. Recent advances in high-speed electronic computers made available a powerful device for performing the computations. In order to follow numerically a turbulent flow, a large number of closely spaced mesh points would be required to include both the large-scale and small-scale effects. It is therefore necessary to confine the range of eddy sizes, so that a suitably low Reynolds number must be chosen. The plane jet was chosen because of the simplicity of the image vortex system required to satisfy the boundary condition. The method could also be applied to the flow past a circular cylinder and the formation of the Kármán vortex street.

SOME EXPERIMENTS WITH SONIC THROATS DOWNSTREAM FROM THE WORKING-SECTION OF A SLOTTED-WALL HIGH-SPEED TUNNEL.
A. Chinneck and N. A. North, National Physical Laboratory. 1957. 26p. diagrs., photos.
ARC R & M 3053; ARC 18,396. (Ask for N-59534*)

Tests have been made in the 9- by 3-inch high-speed tunnel to investigate the use of sonic throats downstream from the working section of a slotted-wall high-speed tunnel employing diffuser suction. It was found that such throats behaved at subsonic speeds in a manner similar to their behavior in a solid-wall tunnel. Tests were made with various configurations, including the conditions which could be expected on the 18- by 14-inch and 36- by 14-inch high-speed tunnels at the N.P.L. It was found that the throat mechanisms at present used with the subsonic liners on these tunnels should work satisfactorily, and that the power required should be of the same order as that required to run the unchoked slotted walls at unit Mach number.

THE PRESENT STATUS OF AIRCRAFT STABILITY PROBLEMS IN THE AEROELASTIC DOMAIN.
A. S. Taylor. December 1957. 29p. RAE Tech. Note Aero 2538. (Ask for N-59676*)

Recent developments in the study of the effects of structural flexibility on aircraft stability and control (with particular reference to dynamic stability) are discussed. The relevant literature, relating to both theoretical and experimental work, is reviewed (section 3) against the theoretical background outlined in section 2, with a view to assessing the importance of these effects and establishing how elaborate a mathematical treatment is necessary to predict them with reasonable accuracy. The advantages of an integrated approach to this and associated aeroelastic problems, whereby the solutions to several related problems may be obtained as special cases of a more generalized problem, are briefly discussed.

THE CALCULATION OF THE INVISCID FLOW BETWEEN A DETACHED BOW WAVE AND A BODY.
K. W. Mangler and M. E. Evans. October 1957. 37p. diagrs. RAE Tech.Note Aero 2536.
(Ask for N-59677*)

The inviscid flow past a symmetrical blunt body at high supersonic speed is calculated by a numerical method. It starts from the shock, the shape of which must be assumed. The region of the flow between the shock and the body which includes the subsonic part is obtained by a step-by-step process and the shape of the body producing the shock is calculated. The remainder of the supersonic part is calculated by the method of characteristics for which the body shape can be prescribed. The results of the calculation obtained for the two-dimensional flow past a circular cylinder at a Mach number of 7 and a specific heat ratio $\gamma = 1.4$ are described in detail.

A THEORY OF THE SEPARATED FLOW FROM THE CURVED LEADING EDGE OF A SLENDER WING.
J. H. B. Smith. November 1957. 25p. diagrs., tabs. RAE Tech.Note Aero 2535.
(Ask for N-59678*)

The simple model used by Brown and Michael to represent the flow past a slender delta wing with leading-edge separation is extended to wings of more general plan form, which still have unswept trailing edges and pointed apexes. The vorticity of the fluid near the leading edge is represented by an isolated vortex of varying strength which is curved in the non-conical cases considered here. A step-by-step method of calculation is used which starts from an assumed conical flow near the apex and employs the condition of zero total force on the vortex system in one cross-flow plane to obtain the configuration in the next. Numerical values of the coordinates and strength of the vortex, the lift coefficient, and the center-of-pressure position are found for three planform families at different incidences.

FINAL REPORT ON SINTERING OF ZINC OXIDE.
J. Hutchings and J. P. Roberts, (with determination of excess zinc by H. J. Allsopp). October 1957.
38p. diagrs., tab. RAE Report Met.93.
(Ask for CN-59996*)

Oxygen enhanced the shrinkage of powder pressings of some zinc oxide materials but retarded the shrinkage of pressings of others. A connection between excess zinc content and chemisorption of oxygen was found. Change in the surface of the oxide, probably involving interstitial zinc-chemisorbed oxygen complexes, was considered to explain enhanced sintering in oxygen. Change of composition of the volume of the oxide was considered to explain retardation of sintering by oxygen. A diffusion model for shrinkage accounted for the observations better than one based on plastic flow. Calculation suggested that zinc diffusion into the pores during sintering occurred predominantly through the grain boundaries. Various subsidiary influences on the sintering were observed and interpreted.

EXPERIMENTS ON MELTING TITANIUM IN OXYGEN DEFICIENT THORIA CRUCIBLES. R. L. Bickerdike, G. Hughes, and D. Clark. January 1958. 12p. photos., tabs. RAE Tech.Note Met.281. (Ask for CN-59999*)

Eight crucibles, of about 8 cc capacity, of composition corresponding to $ThO_{1.5}$ were obtained from the Atomic Weapons Research Establishment, Aldermaston. Samples of titanium were heated in them under vac. at temperatures between 1550° and 1770° C for various periods. After cooling, metallographic examination and hardness measurements were made, oxygen was determined by vacuum fusion, X-ray work was done, and some thorium determinations were made. Titanium was melted in a commercial ThO_2 pot for comparison. The $ThO_{1.5}$ crucibles contained free thorium, and all except one leaked. The metal retained contained particles of a thoria phase, some free thorium, and a small amount of oxygen in solid solution in the titanium; it had a hardness of 172 to 200 D.P.N. A higher hardness, with more oxygen in solid solution resulted from melting in commercial thoria. The $ThO_{1.5}$ material would not be a satisfactory crucible material.

SPECTROGRAPHIC INVESTIGATION OF A CORDITE FLAME AT HIGH PRESSURES. G. A. Heath. December 1957. 22p. diagrs., photos., tabs. RAE Tech.Note RPD 161. (Ask for N-60000*)

The structure of the SU/K cordite flame over the pressure range of 400 to 1600 lb/sq in. (gage) has been studied spectrographically. The intense brightness of the final reaction ("explosion") zone of the flame has been shown to be due to continuous radiation from carbon particles. From quantitative intensity measurements the temperature of the explosion zone at all pressures was found to be 2350° K which is less than the theoretical value assuming no loss of heat by radiation. It is pointed out, however, that this discrepancy could be explained by such loss.

Advisory Group for Aeronautical Research and Development. AIRCRAFT LOADS IN CONTINUOUS TURBULENCE. N. I. Bullen. (Presented at 5th meeting of AGARD Structures and Materials Panel, April 29-May 3, 1957, Copenhagen, Denmark.) April-May 1957. vi, 26p. diagrs., tabs. AGARD Report 116. (Ask for N-48593X)

There is evidence to suggest that the distribution of aircraft normal acceleration is not usually Gaussian, even for very short periods of time, but follows the form of a modified Bessel function, and gives rise to an exponential distribution of peak values. From the distribution of peak values the root-mean-square value of the variable (normal acceleration) can be determined. Where the duration of turbulence has been measured directly, or can be inferred, the number of zero crossings per second of the variable can also be found from the peak distribution. Two examples of this are given, each for two intensities of turbulence.

N-48821X

Advisory Group for Aeronautical Research and Development. CRITICAL FLIGHT CONDITIONS AND LOADS RESULTING FROM INERTIA CROSS-COUPLING AND AERODYNAMIC STABILITY DEFICIENCIES. W. J. G. Pinsker. (Presented at 5th meeting of AGARD Structures and Materials Panel, April 29-May 3, 1957, Copenhagen, Denmark.) April-May 1957. viii, 47p. diagrs. AGARD Report 107. (Ask for N-48821X)

The effects of the gyroscopic forces on aircraft with large inertias during rolling maneuvers are discussed and criteria given for the three resulting divergent flight conditions: yaw divergence, pitch divergence, and autorotational rolling. The critical loading cases in practical rolling maneuvers are discussed and methods for the determination of peak loads outlined. Aircraft responses in inadvertent pitch-up are analyzed and data are given for the estimation of peak loads both for uncontrolled conditions and for pitch-up with pilot's counteraction. The principal causes for loss of directional stability are indicated and possible dangerous flight conditions are outlined.

N-51482X

Advisory Group for Aeronautical Research and Development. A STUDY OF THE CORRELATION BETWEEN FLIGHT AND WIND-TUNNEL BUFFET LOADS. Wilber B. Huston, NACA. (Presented at 5th meeting of AGARD Structures and Materials Panel, Copenhagen, Denmark, April 29-May 3, 1957.) April-May 1957. vi, 25p. diagrs. AGARD Report 111. (Ask for N-51482X)

Methods and concepts developed in the study of random processes are applied to the loads on an airplane wing in buffeting. The power spectrum and probability distribution of the buffet loads as measured by electrical wire resistance strain gages suggest that these loads can be considered as the linear response of a lightly damped single-degree-of-freedom system to a random input. Dimensional analysis and beam theory are employed to develop a relation between the buffet loads on an airplane in flight and the loads on a model in a wind tunnel. Flight and model results are compared for several different configurations.

Advisory Group for Aeronautical Research and Development. A SURVEY OF THE STRUCTURAL PROPERTIES OF SOME HIGH STRENGTH SHEET STEELS. M. A. Melcon, Lockheed Aircraft Corporation. (Presented at 5th meeting of AGARD Structures and Materials Panel, Oslo, Norway, April 24-27, 1957.) April 1957. vii, 25p. diagrs., photos., tabs. AGARD Report 101. (Ask for N-55027X)

This paper deals primarily with the structural properties of the sheet steels; however, a brief strength-weight evaluation of steel, titanium, and aluminum is made for purposes of orientation. The heat-treatable stainless steels which are specifically covered are 420, 422, 422M, AM350, and 17-7PH. Tri-cent and Thermold "J" are also discussed. Mechanical properties at room and elevated temperature are summarized. Stress-strain curves in both tension and compression are presented at room and elevated temperature. Heat treatment, corrosion resistance, and formability of the various alloys are discussed. Some fatigue, creep, and stress-rupture data are presented. Tear strength is evaluated for some of the materials. Fabrication problems such as welding, machining, and distortion during heat treatment are also covered.

N-55379X

Advisory Group for Aeronautical Research and Development. INSTRUMENTATION AND DATA HANDLING METHODS FOR DETERMINING LOAD DISTRIBUTION ON WIND TUNNEL MODELS BY PRESSURE DISTRIBUTION MEASUREMENTS. Joseph P. Doyle, Wright Air Development Center. (Presented at 5th meeting of AGARD Structures and Materials Panel, Copenhagen, Denmark, April 29-May 3, 1957.) April-May 1957. vi, 29p. diagrs., photos. AGARD Report 114. (Ask for N-55379X)

A discussion is presented of pressure distribution measurements on wind-tunnel models from the viewpoint of the instrumentation and data handling requirements. Two types of instrumentation are described, a serial scanning system as employed in testing the Convair B-58 1/17-scale pressure model and a parallel system now being installed in the Wright Air Development Center 10-ft transonic wind tunnel. Some limitations imposed on the data collection by wind-tunnel operations and model geometry and on the subsequent data reduction methods are considered.

Advisory Group for Aeronautical Research and Development. RESPONSE OF ELASTIC AIRCRAFT TO CONTINUOUS TURBULENCE. R. L. Bisplinghoff, T. H. H. Pian, and K. A. Foss, Massachusetts Institute of Technology. (Presented at 5th meeting of AGARD Structures and Materials Panel, Copenhagen, Denmark, April 29-May 3, 1957.) April-May 1957. vi, 20p. diagrs. AGARD Report 117. (Ask for N-56099X)

A review is made of a method for determining the disturbed motion and the corresponding stresses of an elastic aircraft. The method is applied to the solution of the response of aircraft to continuous turbulence. Results are presented of the stress amplification due to flexibility of the structures. Discussions include effects of the scale of turbulence and of the spanwise variations of gust intensity on the responses and stresses of flexible aircraft.

THE MEASUREMENT OF UNSTEADY PRESSURES IN WIND TUNNELS. Eugene L. Davis, Jr. (Presented to Wind Tunnel and Model Testing Panel of Advisory Group for Aeronautical Research and Development, London, England, March 24-28, 1958.) vi, 31p. diagrs. (Ask for N-57669*)

Practical solutions to the problem of accurately measuring unsteady pressures in wind tunnels are described with emphasis on the response of pressure systems, calibration techniques and equipment, and wind-tunnel instrumentation. Basic guides for the selection of a pressure-gage-volume—connecting-tubing system are given. A cam-type pulsator calibrator with a sinusoidal pressure variation up to ±3 pounds per square inch and a frequency range up to 5,000 cycles per second is described. The minimum number of pressure gages required for lift and moment measurements is discussed. A brief comment on the interpretation of pressure fluctuations in terms of velocity fluctuations is given.

CN-58824

Advisory Group for Aeronautical Research and Development. STUDY OF THE RELIABILITY OF IRREVERSIBLE SERVO-SYSTEMS. (Essais d'endurance de servo-commandes irreversibles.) L. Vandenberghe, Centre d'Essais en Vol. (Presented at 10th meeting of AGARD Flight Test Techniques Panel, May 20-24, 1957, London.) May 1957. iii, 6p. (French text). AGARD Report 128. (Ask for CN-58824)

This paper describes the numerous tests imposed on an irreversible servocontrol (with mechanical input) from manufacture up to series installation. These

MISCELLANEOUS

include bench tests of performance, stability (perhaps the most important), preendurance, and endurance, with frequent inspections and periodical check of the dimensions. Flight tests must confirm the proper functioning of the jack in all flight conditions and at the limits of its performance. Finally, there are endurance tests in flight during which the jack is taken out of the aircraft and carefully inspected periodically.

Advisory Group for Aeronautical Research and Development. STRUCTURAL PLASTICS FOR AIRFRAME CONSTRUCTION. N. J. L. Megson. (Presented at 6th meeting of Structures and Materials Panel, Paris, November 4-8, 1957.) November 1957. 16p. tabs. AGARD Report 162.
(Ask for CN-59733)

A general account of the development and methods of fabrication of reinforced plastics which can be molded at low pressures. Discusses various applications, including wings, radomes, fuselages and drop tanks, and the use of plastics in the Fokker "Friendship." Future trends are outlined.

N-59734

Advisory Group for Aeronautical Research and Development. A REVIEW OF LANDING GEAR AND GROUND LOADS PROBLEMS. J. F. McBrearty, Lockheed Aircraft Corp. (Presented at 5th meeting of Structures and Materials Panel, Copenhagen, April 29-May 3, 1957.) April-May 1957. 22p. diagrs., photos., tabs. AGARD Report 118.
(Ask for N-59734)

This paper presents a brief assessment of the aircraft weight attributable to the landing gear and ground loads in general and a discussion of some of the less common ground loads phenomena which have become more and more important to aircraft design. *Skidding oscillations, brake chatter, shimmy,* taxiing loads, and fatigue are singled out for more detailed consideration. Discussion of the methods employed to provide practical solutions to these problems is presented. It is concluded that experimental development techniques in conjunction with analytical methods provide reasonably satisfactory designs but that a great deal of operational data is needed to refine the design targets for these phenomena.

N-59735

Advisory Group for Aeronautical Research and Development. HIGH-SPEED STABILITY AND CONTROL PROBLEMS AS THEY AFFECT FLIGHT TESTING. Malcolm J. Abzug, Douglas Aircraft Company. (Presented at 10th meeting of Flight Test Techniques Panel, London, May 20-24, 1957.) May 1957. 36p. diagrs. AGARD Report 120.
(Ask for N-59735)

Discusses high-speed stability and control flight testing from the standpoints of the maximum envelopes of attainable Mach number and altitude, and load factor and Mach number. Also describes testing techniques which have been used for some special high-speed stability and control problems, and

MISCELLANEOUS

touches upon the flight-testing of irreversible flight-control systems and automatic systems. Concludes that reliance on analytical methods is essential to the success of such a flight-testing program.

N-59736

Advisory Group for Aeronautical Research and Development. NEAR FIELD JET NOISE. M. O. W. Wolfe. (Presented at 5th meeting of Structures and Materials Panel, Copenhagen, April 29-May 3, 1957.) April-May 1957. 41p. diagrs., photo. AGARD Report 112. (Ask for N-59736)

This paper deals with the subject of jet engine noise in relation to its effects on aircraft structures. Near field noise measurements are described for a range of jet shear velocities on two representative turbojet engines, one of them operating with an afterburner. Contours of equal noise pressure in the horizontal plane containing the axis of the jet are presented for a range of shear velocity for overall noise pressure and for noise pressures in 1/3 octave frequency bands in the noise spectra. In the velocity range 790 to 1800 ft/sec, 400 cycles/sec is the dominant frequency. At most velocities the noise pressures at this frequency are about 10 decibels less than the corresponding overall noise pressures. The increase in noise level due to reheat is not as great as would have been predicted from a consideration of the noise level trends at much lower values of velocity without reheat.

UNPUBLISHED PAPERS

N-58772*

Stanford University. INVESTIGATION OF AIRFOILS, PLATES, GRIDS, AND RODS FOR BOUNDARY LAYER CONTROL IN SUBSONIC DIFFUSERS. C. A. Moore and S. J. Kline. (Progress report.) August 16, 1954. 56p. diagrs., photos., tabs. Stanford U. (Ask for N-58772*)

Progress on a current program to investigate the use of vanes and other mechanical means for the control of the boundary layer in diffusers is reported. Two main aspects of the work are covered: (1) Design and construction of a full-scale air diffuser with a wide range of experimental flexibility; and (2) study of the flow regimes and boundary-layer behavior in a water-table model. The air apparatus is now essentially complete. Its performance has not been checked, and a few modifications may still be required. The water-table tests have proved very fruitful and the effects observed or deduced are discussed.

N-58790*

Stanford University. SOME NEW MECHANISMS AND CONCEPTIONS OF STALL INCLUDING THE BEHAVIOR OF VANED AND UNVANED DIFFUSERS. Stephen J. Kline. March 15, 1957. 112p. diagrs. Stanford U. MD-1. (Ask for N-58790*)

The flow in subsonic, plane-walled, two-dimensional diffusers with thin inlet boundary layers is discussed. It is shown that only some of the results found in unvaned diffusers and little or none of the results found for vaned diffusers can be rationalized by arguments based solely on the conventional model of the flow employing a two-dimensional boundary layer. The work is primarily qualitative in nature; this applies both to the discussion of mechanisms and to the rationalization of performance based on the resulting concepts. While fragmental mathematical analyses are given, they are used primarily to bolster the arguments rather than as proofs. This is in keeping with the objective of the discussion which is to attempt to clarify, distinguish, and explain the basic flow models for the various types of stall.

N-59502*

THE HEAT CONDUCTIVITY OF AQUEOUS SOLUTIONS OF STRONG ELECTROLYTES. (Die Wärmeleitfahigheit von wässrigen Lösungen starker Elektrolyte.) L. Riedel. 16p. diagrs., tabs. Translation from Chemie-Ingenieur-Technik, v. 23, 1951, p. 59-64. (Ask for N-59502*)

In ideal solutions of strong electrolytes each type of ion will have its own particular effect on the thermal conductivity λ of the solution. The effect is an independent property of the ion. The separable effect of each type of ion may therefore be added to give the total effect. From plots of λ against molar concentration for several common electrolytes, the effect of each type of ion on λ was determined and tabulated relative to the sodium ion on the basis of 1 mole. It was also found that the temperature dependence of λ for water and for a given solution was essentially the same. Thus, λ for many solutions may be predicted for a given temperature and concentration knowing only the properties of water and the tabulated relative ion values. The text reviews the data of several other authors.

NACA RM A50C30

WIND-TUNNEL TESTS OF A 0.16-SCALE MODEL OF THE X-3 AIRPLANE AT HIGH SUBSONIC SPEEDS. - ADDITIONAL STABILITY AND CONTROL CHARACTERISTICS AND THE AERODYNAMIC EFFECTS OF EXTERNAL STORES AND RAM JETS. Joseph W. Cleary and Jack A. Mellenthin. June 13, 1950. 86p. diagrs., photos., tabs. (NACA RM A50C30)

Additional wind-tunnel tests of the 0.16-scale X-3 model were made at low and high subsonic Mach numbers to investigate the static longitudinal and lateral stability and control characteristics of a variety of model configurations. Included are the effects of dive brakes, external stores, and wing-tip ram jets on the stability characteristics and measurements of the effectiveness of the aileron, leading-edge flaps, and horizontal tail. The results indicated generally satisfactory stability and control characteristics at all Mach numbers of the test.

NACA RM A50D07

WIND-TUNNEL TESTS OF A 0.16-SCALE MODEL OF THE X-3 AIRPLANE AT HIGH SUBSONIC SPEED - WING AND FUSELAGE PRESSURE DISTRIBUTION. Joseph W. Cleary and Jack A. Mellenthin. June 22, 1950. 61p. diagrs., photos. (NACA RM A50D07)

Wind-tunnel measurements of wing and fuselage pressure distribution were made in pitch and in yaw at Mach numbers from 0.40 to 0.925 on a 0.16-scale model of the projected X-3 research airplane. The wing pressure distributions are presented for leading-edge-flap angles of 0°, 10°, and 30°. Also included are measurements of total pressure in the fuselage boundary layer at the location of the left boundary-layer bleed scoop.

NACA RM A52L04a

DAMPING IN PITCH OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS. Murray Tobak. April 1953. ii, 107p. diagrs. (NACA RM A52L04a)

The concept of indicial functions is applied to the analysis of the short-period pitching mode of wings in subsonic and supersonic flight. The effects on the rotary-damping-moment coefficient of changes in Mach number, aspect ratio, plan form, frequency, and thickness are investigated and the results compared with the results of a series of experiments for low-aspect-ratio wing-body combinations. The experimental results, obtained over the Mach number ranges 0.6 to 0.9 and 1.2 to 1.9 were in good agreement with the results of theoretical computations and confirmed the theoretical predictions of the existence of ranges of supersonic Mach number and center-of-gravity positions over which dynamic instability may be expected. The occurrence at high subsonic Mach numbers of small-amplitude self-sustained oscillations is noted and a hypothesis advanced for its explanation.

NACA RM A53D10

WIND-TUNNEL INVESTIGATION OF THE VORTEX WAKE AND DOWNWASH FIELD BEHIND TRIANGULAR WINGS AND WING-BODY COMBINATIONS AT SUPERSONIC SPEEDS. J. Richard Spahr and Robert R. Dickey. June 1953. 92p. diagrs., photos., tabs. (NACA RM A53D10)

An investigation has been made to observe visually the vortex wake behind triangular wings of aspect ratios from 0.67 to 4 in combination with a pointed cylindrical body at Mach numbers of 1.5 and 2.0, and to measure the downwash field associated with these vortex systems. An analytical method based on existing theories is applied to the prediction of these downwash distributions.

NACA RM A53D27

AN EXPERIMENTAL INVESTIGATION AT SUBSONIC AND SUPERSONIC SPEEDS OF THE TORSIONAL DAMPING CHARACTERISTICS OF A CONSTANT-CHORD CONTROL SURFACE OF AN ASPECT RATIO 2 TRIANGULAR WING. David E. Reese, Jr. July 1953. 32p. diagrs., photos., tab. (NACA RM A53D27)

The results of an investigation of the torsional damping characteristics of a constant-chord control surface mounted on a triangular wing of aspect ratio 2 are presented. The effects of variations in control surface oscillation amplitude, angle of attack, and frequency were investigated at subsonic and supersonic Mach numbers. A cancellation technique for obtaining these data in forced-oscillation tests is described.

NACA RM A54D22

INVESTIGATION OF THE NORMAL FORCE ACCOMPANYING THRUST-AXIS INCLINATION OF THE NACA 1.167-(0)(03)-058 AND THE NACA 1.167-(0)(05)-058 THREE-BLADE PROPELLERS AT FORWARD MACH NUMBERS TO 0.90. Fred A. Demele and William R. Otey. June 1954. 31p. diagrs., photo., tab. (NACA RM A54D22)

Presented are results of an investigation of the normal force of two three-blade propellers, differing only in blade thickness-chord ratio. Data are included for several blade angles and angles of attack at Mach numbers to 0.90. The experimental normal force is compared with that calculated by a theoretical method developed herein.

NACA RM A55C28

EXPLORATORY INVESTIGATION OF THE LOW-SPEED STATIC STABILITY OF A CONFIGURATION EMPLOYING THREE IDENTICAL TRIANGULAR WING PANELS AND A BODY OF EQUAL LENGTH. Noel K. Delany. April 1955. 25p. diagrs., photos. (NACA RM A55C28)

Results are presented of an experimental investigation of the low-speed static-stability characteristics of a simplified model of an unusual configuration. The model had three identical triangular airfoils of low aspect ratio, two forming wings and one a vertical fin. The airfoils were radially disposed about a central body which had the same length as the airfoils. Results of a cursory investigation of elevator and rudder effectiveness and of the effects of changes in dihedral are also included.

#NACA RM A55D18a, by Triplett

NACA RM A55D27a

A COMPARISON AT MACH NUMBERS UP TO 0.92 OF THE CALCULATED AND EXPERIMENTAL DOWNWASH AND WAKE CHARACTERISTICS AT VARIOUS HORIZONTAL TAIL HEIGHTS BEHIND A WING WITH 45° OF SWEEPBACK. Jack D. Stephenson, Ralph Selan, and Angelo Bandettini. June 1955. 81p. diagrs., photos., tabs. (NACA RM A55D27a)

Results of downwash and dynamic-pressure surveys in the region of the tail of a wing-fuselage-tail model having a wing (of aspect ratio 5.5) swept back 45° are presented and discussed. A comparison of the downwash measured locally with the downwash calculated by two methods indicated that the effects of tail height and of partial stalling of the wing on downwash were not accurately predicted by either method.

NACA RM A56C01

THE EFFECTS OF BLOWING OVER VARIOUS TRAILING-EDGE FLAPS ON AN NACA 0006 AIRFOIL SECTION, COMPARISONS WITH VARIOUS TYPES OF FLAPS ON OTHER AIRFOIL SECTIONS, AND AN ANALYSIS OF FLOW AND POWER RELATIONSHIPS FOR BLOWING SYSTEMS. Jules B. Dods, Jr., and Earl C. Watson. June 1956. 145p. diagrs., photos., tab. (NACA RM A56C01)

The results are presented of a two-dimensional investigation conducted to determine the effect of blowing over various types of trailing-edge flaps on a wing having the NACA 0006 airfoil section and a drooped-nose flap. The position and profile of the trailing-edge flap, the nozzle height, and the location of the flap with respect to the nozzle were found to be important variables. Data from many investigations were used to make an evaluation of the effects of blowing on lift. An analysis was made of flow and power relationships for blowing systems.

NACA RM A56D02

THE EFFECT OF CONICAL CAMBER ON THE STATIC LONGITUDINAL, LATERAL, AND DIRECTIONAL CHARACTERISTICS OF A 45° SWEPTBACK WING AT MACH NUMBERS UP TO 0.96. Robert I. Sammonds and Robert M. Reynolds. July 1956. 64p. diagrs., tabs. (NACA RM A56D02)

The aerodynamic forces and static stability characteristics were measured for wing-body combinations having an aspect-ratio-3, 45° sweptback wing. The wing sections perpendicular to the quarter-chord line were NACA 64A006 with increased leading-edge radii. Tests were made both with and without conical camber, and with and without roughness strips, at Mach numbers up to 0.96 at a Reynolds number of 1.5 million, and at Reynolds numbers up to 8 million at a Mach number of 0.22.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM A56D05

THE EFFECT OF FLUID INJECTION ON THE COMPRESSIBLE TURBULENT BOUNDARY LAYER - THE EFFECT ON SKIN FRICTION OF AIR INJECTED INTO THE BOUNDARY LAYER OF A CONE AT M = 2.7. Thorval Tendeland and Arthur F. Okuno. June 1956. 23p. diagrs. (NACA RM A56D05)

The effects of transpiration air flow on the average skin-friction coefficient and pressure drag of a conical model are presented. Air was injected into the turbulent boundary layer at several rates of flow through a truncated porous cone oriented at zero angle of attack to the airstream. The Mach number was 2.71 and the Reynolds number range was 6.25×10^6 to 8.56×10^6 per foot.

NACA RM A56D06

A HORIZONTAL-TAIL ARRANGEMENT FOR COUNTERACTING STATIC LONGITUDINAL INSTABILITY OF SWEPTBACK WINGS. George G. Edwards and Howard F. Savage. May 1956. 51p. diagrs., photos., tab. (NACA RM A56D06)

Horizontal-tail surfaces mounted on booms extending rearward from approximately the midsemispan of a sweptback wing were investigated as a means of improving static longitudinal stability. The results of exploratory wind-tunnel tests showing the longitudinal characteristics of a 45° sweptback wing and a fuselage in combination with these outboard tails are compared with those obtained using a conventional sweptback tail at Mach numbers up to 0.92. The outboard tails were very effective in preventing static longitudinal instability.

NACA RM A56D23

THE USE OF AREA SUCTION FOR THE PURPOSE OF IMPROVING THE LONGITUDINAL CHARACTERISTICS OF A THIN UNSWEPT-WING MODEL EQUIPPED WITH LEADING- AND TRAILING-EDGE FLAPS. David G. Koenig. July 1956. 52p. diagrs., photo., tabs. (NACA RM A56D23)

The increase in trailing-edge-flap lift increment obtained by applying porous area suction to the knees of full-span leading-edge flaps and part-span trailing-edge flaps was investigated, in the Ames 40- by 80-foot wind tunnel, on a model with an aspect-ratio-3 unswept wing with sharp leading edges. The wing section was a modified double wedge 4.2 percent thick. Most of the tests were made at a Reynolds number of 9.4×10^6 and a Mach number of 0.11.

NACA RM A56F12

ANALYSIS OF SOME PARAMETERS USED IN CORRELATING BLOWING-TYPE BOUNDARY-LAYER CONTROL DATA. Mark W. Kelly. September 1956. 19p. diagrs. (NACA RM A56F12)

A theoretical analysis of the limitations to the use of the jet momentum coefficient as a correlating parameter in blowing boundary-layer control research is presented. This analysis indicates that this parameter should be acceptable when the jet velocity is large compared to the local-stream velocity. However, when the jet velocity is of the same order as the local velocity, the correlating parameter should include a term involving the flow quantity and the ratio of the local velocity to free-stream velocity. Data are shown to substantiate this conclusion.

NACA RM E51C16

INTERNAL FLOW AND BURNING CHARACTERISTICS OF 16-INCH RAM JET OPERATING IN A FREE JET AT MACH NUMBERS OF 1.35 AND 1.73. Eugene Perchonok and John M. Farley. May 21, 1951. 37p. diagrs., photos., tab. (NACA RM E51C16)

The effects of mass-flow ratio on the additive drag and normal-shock position of a single oblique-shock diffuser are presented. Also evaluated is the variation with operating condition of the velocity distribution at the combustion-chamber inlet. A comparison with connected-pipe data is included. Burner performance with a corrugated gutter-grid flame holder is discussed. It is shown that the total-pressure drop across the combustion chamber can be predicted with reasonable accuracy from the computed flame holder and combustion momentum pressure losses.

II - AERODYNAMIC LOAD DISTRIBUTIONS OF SERIES OF FIVE BODIES HAVING CONICAL NOSES AND CYLINDRICAL AFTERBODIES. John R. Jack and Lawrence I. Gould. May 1952. 28p. diagrs., photos., tabs. (NACA RM E52C10)

The results of an investigation to determine the aerodynamic load distributions of a series of five bodies having conical or slightly blunted noses at a Mach number of 3.12 for a Reynolds number range of 2 x 10^6 to 14 x 10^6 and angles of attack from 0° to 9° are presented and compared with theoretical calculations. Comparison of the experimental pressure data with linear and second-order theories showed good agreement for low angles of attack. The conical pressures were predicted well by second-order theory for all angles of attack.

EXPERIMENTAL INVESTIGATION OF AXIAL-FLOW COMPRESSOR STATOR BLADES DESIGNED TO OBTAIN HIGH TURNING ANGLES BY MEANS OF BOUNDARY-LAYER SUCTION. G. R. Costello, R. L. Cummings, and G. K. Serovy. June 1952. 22p. diagrs., photos., tab. (NACA RM E52D18)

In order to determine the practicability of using blade boundary-layer control to obtain high turning angles in a stator-blade row, a set of slotted stator blades, designed by a potential-flow method for a 45° turning angle with a low solidity using 1 percent boundary-layer bleed, was tested in a single-stage compressor. Several slot configurations were tested in order to reduce the large secondary flows produced by the original blades. In addition, a means of boundary-layer control was installed on the hub ahead of the stator blades to improve the entrance conditions. The overall performance of the stage was obtained for a range of weight flows at each of three speeds with and without hub suction. These results together with wake surveys indicate that, although design turning was obtained, the slots created large local pressure gradients which caused separation from the walls and greatly increased the secondary flows.

NACA RM E52D25

INVESTIGATION OF PERFORMANCE OF SEVERAL DOUBLE-SHROUD EJECTORS AND EFFECT OF VARIABLE-AREA EXHAUST NOZZLE ON SINGLE EJECTOR PERFORMANCE. C. W. Ellis, D. P. Hollister, and H. D. Wilsted. July 1952. 25p. diagrs., photos. (NACA RM E52D25)

An investigation was made to determine briefly the characteristics of a double-shroud cooling-air ejector. Also, the performance of single-shroud ejector having a clamshell-type variable-area actuating nozzle was compared with that of an ejector having a conical nozzle. For the models investigated, the experimental results indicated that the differences in the variable-area and conical nozzle ejector performance are due primarily to flow restrictions in the cooling passage introduced by the clamshell protrusions, rather than the nonplanar and noncircular exit. The investigation of double-shroud-ejector performance, while not completely general in application, does indicate that an ejector of this type could be designed to operate satisfactorily, that is, with a ratio of tertiary to secondary air weight flow of about 0.2. In order to obtain such performance, the difference between the diameter ratios and spacing ratios of the two shrouds should be small.

NACA RM E53C17

DYNAMIC CHARACTERISTICS OF A SINGLE-SPOOL TURBOJET ENGINE. R. T. Craig, George Vasu, and R. D. Schmidt. August 1953. 50p. diagrs., tab. (NACA RM E53C17)

The linearized dynamic characteristics of a single-spool turbojet engine with variable exhaust-nozzle area are presented for a range of altitudes at a constant flight Mach number. The information was obtained by subjecting the engine to varied-size, independent variable step disturbances. Effects of step size, exhaust-nozzle area, engine speed, and flight altitude on the dynamic terms are presented. The regions of usefulness of the linearized first-order description of the engine are delineated.

NACA RM E53D02

CHARACTERISTICS OF A HYDRAULIC CONTROL DETERMINED FROM TRANSIENT DATA OBTAINED WITH A TURBOJET ENGINE AT ALTITUDE. George Vasu, William L. Hinde, and R. T. Craig. June 1954. 62p. diagrs., photo., tab. (NACA RM E53D02)

An analysis was conducted to determine pertinent characteristics of a hydraulic control for turbojet engines. A frequency-response analysis of transient data yielded the transfer function of the speed - fuel flow control. Studies with an analog computer substantiated the results of the frequency-response analysis and also indicated the existence of additional small lags not detectable by the frequency analysis. The schedule for the surge control was obtained from the response of engine variables to throttle burst accelerations from idle to full thrust. The investigation revealed some difficulties with the present control and therefore a modification of the control which

UNAVAILABLE; contains proprietary or obsolete information.

DECLASSIFIED NACA RESEARCH REPORTS

more closely matches the engine surge characteristics for a broad range of engine and flight conditions is suggested.

NACA RM E53D08

PRELIMINARY EXPERIMENTAL INVESTIGATION OF TRANSPIRATION COOLING FOR AN AFTERBURNER WITH A SINTERED, POROUS STAINLESS-STEEL COMBUSTION-CHAMBER WALL. William K. Koffel. June 1953. 47p. diagrs., photos., tabs. (NACA RM E53D08)

The application of transpiration air-cooling to the combustion-chamber wall of an afterburner was investigated experimentally on a full-scale afterburner having a combustion-chamber wall fabricated from sintered, porous stainless-steel plates. The temperatures of the hot-gas surface of the porous wall were correlated in terms of the temperatures of the combustion gas and cooling air against the ratio of the cooling-air flux density normal to the porous wall to the mass flow of combustion gases per unit of combustion-chamber flow area.

NACA RM E53D09

INTERNAL PERFORMANCE CHARACTERISTICS OF VARIABLE-THROAT PLUG- AND VANED-TYPE CONVERGENT-DIVERGENT NOZZLES. H. George Krull, Fred W. Steffen, and Carl C. Ciepluch. June 1953. 34p. diagrs., photo. (NACA RM E53D09)

As part of an overall program for the experimental investigation of large-scale jet nozzles, the internal performance characteristics of three types of variable-throat convergent-divergent nozzles were obtained over a wide range of pressure ratios. The experimental results obtained with one of these nozzles were applied to a typical flight plan of a ram-jet missile. There were only small differences in peak thrust coefficient between the three types of variable-throat convergent-divergent nozzles. The peak thrust coefficients obtained with these nozzles approached or equaled those obtained with several fixed-geometry convergent-divergent nozzles from a previous investigation. There was little gain (1 percent or less) obtained in the peak thrust coefficient of a convergent-divergent plug-type nozzle when the sharp corner of a simple conical center plug was rounded. By proper matching of a variable-throat convergent-divergent nozzle to a typical flight plan of a ram-jet missile, a thrust coefficient of 0.95 was obtained over a flight Mach number range from 2.13 to 3.0. With the performance characteristics of the variable-throat nozzles investigated, this maximum thrust coefficient was obtained by matching the nozzle expansion ratio to the flight plan at the minimum flight Mach number and allowing the nozzle to operate underexpanded at the higher flight Mach numbers.

NACA RM E53D13

INVESTIGATION OF 16-INCH IMPULSE-TYPE SUPERSONIC COMPRESSOR WITH ROTOR TURNING PAST AXIAL DIRECTION. John J. Jacklitch, Jr., and Melvin J. Hartmann. July 1953. 29p. diagrs., photos. (NACA RM E53D13)

Performance data and characteristics are presented for a 16-inch impulse-type supersonic-compressor rotor (as a separate component and as a stage) with turning in the rotor passage beyond the axial direction. This experimental investigation was conducted with Freon-12 as the test medium. As a separate component, the rotor produced a total-pressure ratio of about 5.4 and an adiabatic efficiency of about 0.76. However, the diffusing stators reduced the stage performance much more than expected.

NACA RM E53D16

TURBINE DESIGN CONSIDERATIONS FOR TURBINE-PROPELLER ENGINE OPERATING OVER A RANGE OF FLIGHT CONDITIONS. Elmer H. Davison. June 1953. 20p. diagrs., tab. (NACA RM E53D16)

The turbine design requirements for turbine propeller engines were studied by investigating the turbine design requirements of a turbine for an engine with known compressor characteristics operating over a range of flight conditions from take-off up to speeds of 600 miles per hour at an altitude of 40,000 feet. It was concluded that the turbine design requirements for a turbine-propeller engine should be based on a consideration of the range of flight conditions over which the engine is to perform. Both constant- and variable-exhaust-nozzle-area operation resulted in efficient engine performance, and satisfactory turbine designs were obtainable for either mode of engine operation. The constant-exhaust-nozzle-area operation resulted in more severe turbine design requirements than variable-exhaust-nozzle-area operation. However, the variations in exhaust-nozzle area required for efficient engine operation were quite large.

EXPERIMENTAL INVESTIGATION OF ROTATING STALL AND BLADE VIBRATION IN THE AXIAL-FLOW COMPRESSOR OF A TURBOJET ENGINE. Merle C. Huppert, Howard F. Calvert, and André J. Meyer. April 1954. 24p. diagrs., tabs. (NACA RM E54A08)

A compressor-blade-vibration survey was conducted on a production turbojet engine incorporating an axial-flow compressor with a pressure ratio of approximately 7. Resistance wire strain gages were used to measure the vibratory stress in the first-stage rotor blades, and the flow fluctuations due to

UNAVAILABLE; contains proprietary or obsolete information.

DECLASSIFIED NACA RESEARCH REPORTS

rotating stall were detected and measured by use of the constant-temperature hot-wire anemometer. The investigation was conducted with three different guide-vane assemblies and four jet-nozzle sizes. High vibratory stresses were measured in two distinct speed ranges. The cause of the high vibratory stresses in both speed ranges was determined to be resonant excitation due to rotating stall.

NACA RM E54C22

ANALYSIS OF FACTORS AFFECTING SELECTION AND DESIGN OF AIR-COOLED SINGLE-STAGE TURBINES FOR TURBOJET ENGINES. I - TURBINE PERFORMANCE AND ENGINE WEIGHT-FLOW CAPACITY. Richard J. Rossbach, Wilson B. Schramm, and James E. Hubbartt. May 1954. 50p. diagrs., tab. (NACA RM E54C22)

Turbine blade cooling not only permits higher turbine inlet temperatures for improving turbojet cycle performance but also permits large increases in the obtainable compressor pressure ratio and the engine weight-flow capacity by providing an independent control of the turbine-inlet temperature and the turbine blade stresses. These increases in the compressor pressure ratio and engine weight flow must be reflected into the turbojet-engine performance in order to evaluate accurately the advantages and design of air-cooled turbines. The compressor pressure ratios and the engine weight-flow capacity for turbojets equipped with single-stage air-cooled turbines have been computed and are presented herein for wide ranges in turbine design specifications. High aerodynamic limits are imposed upon each engine component to assure high turbine work and high component weight-flow capacities.

NACA RM E54C24

JET EFFECTS ON PRESSURE LOADING OF ALL-MOVABLE HORIZONTAL STABILIZER. Alfred S. Valerino. June 1954. 27p. diagrs., photo., tab. (NACA RM E54C24)

An investigation was conducted at Mach numbers 0.63, 1.5, and 1.8 to determine the effects of an exhaust jet on the pressure loadings of an all-movable, 45° sweptback horizontal stabilizer located in a region influenced by the jet, and the effects of the stabilizer on the drags of the boattail, base annulus, and secondary-flow passage. Results indicate that at pressure ratios of 1 to 9 the exhaust jet did not appreciably affect the pressure loadings of the stabilizer. The presence of the stabilizer resulted in large increases in the drags of the base annulus and secondary-flow passage.

NACA RM E54D01

EFFECT OF MECHANICALLY INDUCED SINUSOIDAL AIR-FLOW OSCILLATIONS ON OPERATION OF A RAM-JET ENGINE. E. E. Dangle, A. J. Cervenka, and Eugene Perchonok. June 1954. 24p. diagrs., tab. (NACA RM E54D01)

An experimental investigation conducted in a 16-inch ram-jet engine has shown the degree to which inlet flow pulsations influence the combustion efficiency and lean blow-out limit of a ram-jet combustor. It is shown that pulsed air flow affects combustion efficiency and lean blow-out limit depending upon flame-holder configuration, fuel-injector location, and frequency of flow pulsation. The influence of the combustor on inlet flow pulsations is also reported. Investigation has shown that a combustor may amplify or attenuate inlet pressure pulsations. The degree to which the combustor attenuates pressure pulsations is dependent upon the flame-holder pressure loss coefficient, while the degree to which a combustor amplifies pressure pulsations depends on the engine total-temperature ratio τ. As τ increases, the amount by which the combustor amplifies the pressure pulse also increases.

NACA RM E54D06

PUMPING AND DRAG CHARACTERISTICS OF AN AIRCRAFT EJECTOR AT SUBSONIC AND SUPERSONIC SPEEDS. Gerald C. Gorton. June 1954. 19p. diagrs. (NACA RM E54D06)

An investigation was conducted on a cylindrical-shroud ejector (diameter ratio of 1.2 and spacing ratio of 0.80) at free-stream Mach numbers of 0.1, 0.6, 1.6, and 2.0 for a wide range of weight-flow ratio and primary pressure ratio. The results indicate no effect of free-stream Mach number or angle of attack on the pumping characteristics. Boattail pressure-drag and base pressure-drag coefficients decreased with increasing primary pressure ratio, similar to conventional nozzles, and also decreased as weight-flow ratio was increased. The results also indicate that the internal geometry of the secondary passage at the exit station of the primary nozzle was critical in effecting a decrease in primary-nozzle mass-flow coefficient as the weight-flow ratio was increased to values greater than 0.10.

NACA RM E54D21

ANALYSIS OF FACTORS AFFECTING SELECTION AND DESIGN OF AIR-COOLED SINGLE-STAGE TURBINES FOR TURBOJET ENGINES. II - ANALYTICAL TECHNIQUES. Richard J. Rossbach. June 1954. 29p. diagrs. (NACA RM E54D21)

The design freedom provided by turbine cooling is a basis for improving both the turbine and overall engine performance. In order to explore the range of engine operation that can be made possible in this way, analytical techniques are developed herein to determine the design performance of single-stage air-cooled turbines operating over wide ranges in the turbine design specifications. In addition, analytical techniques are developed that utilize the turbine specifications and turbine performance to determine the design performance for both nonafterburning and afterburning engines.

UNAVAILABLE; contains proprietary or obsolete information.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E54D22

PERFORMANCE OF A SUPERSONIC ROTOR HAVING HIGH MASS FLOW. Ralph L. Schacht, Arthur W. Goldstein, and Harvey E. Neumann. July 1954. 34p. diagrs., photo., tab. (NACA RM E54D22)

Experimental investigation was made of a rotor designed for supersonic internal flow, which developed a pressure ratio of 5.3 at an equivalent air speed of 1480 feet per second and a flow of 31.5 pounds per frontal area. Some results were obtained on the effect of inlet Mach number, leading-edge sweep, casing pressure distribution, and accuracy of the approximation of axially symmetric internal flow.

NACA RM E54D23

PERFORMANCE OF MIXED-FLOW IMPELLER, MODEL MFI-1B, WITH DIFFUSER VANES AT EQUIVALENT IMPELLER SPEEDS FROM 1100 TO 1700 FEET PER SECOND. Walter M. Osborn. June 1954. 16p. diagrs., photo. (NACA RM E54D23)

An investigation was made of the performance characteristics of a mixed-flow impeller, model MFI-1B, in combination with a vaned diffuser. The peak pressure ratio and maximum efficiency at an equivalent speed of 1700 feet per second with a vane inlet angle of 66° were 5.39 and 0.733, respectively. An analysis of the data indicates that a pressure ratio of 6.0 and an efficiency of 0.72 can be obtained at an equivalent impeller speed of 1800 feet per second with a vane inlet angle of 69°.

NACA RM E54F16a

ANALYSIS OF FACTORS AFFECTING SELECTION AND DESIGN OF AIR-COOLED SINGLE-STAGE TURBINES FOR TURBOJET ENGINES. III - ENGINE DESIGN-POINT PERFORMANCE. James E. Hubbartt, Richard J. Rossbach, and Wilson B. Schramm. September 1954. 41p. diagrs., tab. (NACA RM E54F16a)

Turbine blade cooling permits engine design freedom which can be exploited to improve both the turbine and the overall turbojet-engine performance. The thrust and thrust specific fuel consumption for both nonafterburning and afterburning turbojet engines equipped with single-stage air-cooled turbines have been determined for wide ranges of coolant-flow ratios, turbine-inlet temperatures, and other turbine design specifications. The results of this analysis showed that the thrust of turbojet engines would be increased in excess of 300 percent for the nonafterburning engines and 100 percent for the afterburning engines as the turbine design specifications are varied over the range considered.

NACA RM E55C09

ANALYSIS OF FACTORS AFFECTING SELECTION AND DESIGN OF AIR-COOLED SINGLE-STAGE TURBINES FOR TURBOJET ENGINES. IV - COOLANT-FLOW REQUIREMENTS AND PERFORMANCE OF ENGINES USING AIR-COOLED CORRUGATED-INSERT BLADES. Henry O. Slone and James E. Hubbartt. May 1955. 45p. diagrs., photos., tab. (NACA RM E55C09)

Overall turbojet-engine performance may be improved by using turbine blade cooling to permit additional engine design freedom. Estimated minimum cooling requirements, related engine performance, and effects of factors influencing cooling were determined for engines equipped with single-stage turbines using air-cooled corrugated-insert blades. Wide ranges of turbine design specifications were considered for a flight Mach number of 2 at 50,000-ft altitude; however, the effects of flight Mach number and altitude were illustrated. The results showed that this blade may permit increases in turbine-inlet temperature to about 3000° and 3500° R for tip speeds of 1700 and 1100 ft/sec, respectively.

NACA RM E55D07a

COMBUSTION OF ALUMINUM BOROHYDRIDE IN A SUPERSONIC WIND TUNNEL. Edward A. Fletcher, Robert G. Dorsch, and Melvin Gerstein. June 1955. 72p. diagrs., photos., tabs. (NACA RM E55D07a)

The feasibility of adding heat to a supersonic airstream in the absence of flame holders was studied. Transient burning for periods of 3 to 10 milliseconds was achieved in a supersonic wind tunnel at nominal Mach numbers of 1.5, 2, 3, and 4. Steady burning was achieved for periods of 0.2 to 2 seconds at nominal Mach numbers of 1.5, 2, and 3. Burning and tunnel flow phenomena, including thermal choking, are described. Suggestions are made for possible applications of the results of this study.

NACA RM E55D21

MATCHING OF AUXILIARY INLETS TO SECONDARY-AIR REQUIREMENTS OF AIRCRAFT EJECTOR EXHAUST NOZZLES. Donald P. Hearth, Gerald W. Englert, and Kenneth L. Kowalski. August 1955. 39p. diagrs. (NACA RM E55D21)

The problem associated with matching secondary-air requirements of ejector exhaust nozzles and auxiliary inlets is analyzed for free-stream Mach numbers up to 2.0. A method for matching the components is presented. The analysis indicates that inlets located in the free stream supply higher pressure recovery than ejectors generally require for optimum net internal thrust at Mach numbers above about 1.4. Consequently, net-internal-thrust gains may be achieved by immersing the auxiliary inlet in a boundary layer where the inlet-momentum penalty is less.

NACA RM E55D22

AN ANALYSIS OF RAM-JET-ENGINE TIME DELAY FOLLOWING A FUEL-FLOW DISTURBANCE. Fred A. Wilcox and Arthur R. Anderson. June 1955. 38p. diagrs., tabs. (NACA RM E55D22)

An analytical method of predicting ram-jet-engine time delay is presented and discussed. The total time delay is assumed to consist of the time for fluid propagation downstream from the fuel injector to the exhaust-nozzle throat plus the time for wave propagation upstream from the nozzle to the sensing station. The time delays of the complete engine as well as its individual components are evaluated theoretically for several rates of heat addition and compared with experimental values. Methods for the reduction of the total time delay are discussed.

NACA RM E55F07

A PRELIMINARY INVESTIGATION OF STATIC-PRESSURE CHANGES ASSOCIATED WITH COMBUSTION OF ALUMINUM BOROHYDRIDE IN A SUPERSONIC WIND TUNNEL. Robert G. Dorsch, John S. Serafini, and Edward A. Fletcher. August 1955. 12p. diagrs., photos. (NACA RM E55F07)

Static-pressure changes resulting from steady combustion of aluminum borohydride in a supersonic wind tunnel were studied. Static pressures were measured along the top wall of a 3.84- by 10-inch tunnel adjacent to the flame that filled the upper portion of the test section. Pressure increases of the order of 20 to 40 percent of the initial static pressure were measured during combustion. The magnitude of the pressure changes suggests that further use of aluminum borohydride to study the effects of heat addition on supersonic flow is warranted.

NACA RM E55I20a

A STUDY OF LIQUID BORIC OXIDE PARTICLE GROWTH RATES IN A GAS STREAM FROM A SIMULATED JET ENGINE COMBUSTOR. Paul C. Setze. April 1957. 41p. diagrs., photos., tab. (NACA RM E55I20a)

It was experimentally determined that the liquid boric oxide particles leaving a jet engine combustor, burning a boron-containing fuel, will have diameters of 1.0×10^{-5} to 2.0×10^{-5} centimeter. For this size range the particle heat-transfer and drag coefficients are essentially infinite. The results may be applied to any boron-containing fuel. Equations are developed that enable the calculation of the particle size-time history. A study of boric oxide deposition mechanisms is included, and suggestions for decreasing deposition rates given.

NACA RM E56A12

FABRICATION AND ENDURANCE OF AIR-COOLED STRUT-SUPPORTED TURBINE BLADES WITH STRUTS CAST OF X-40 ALLOY. Eugene F. Schum, Francis S. Stepka, and Robert E. Oldrieve. April 1956. 39p. diagrs., photos., tabs. (NACA RM E56A12)

A method of fabricating air-cooled, strut-supported turbine blades with struts cast of high-temperature alloy X-40 was developed, and the blade durability was determined in a modified turbojet engine. Thirty blades were investigated at root stress levels of 15,000, 27,000, and 35,000 psi at a turbine-inlet gas temperature of about 1650° F. Early failures at the root region of the blades at the two highest stress levels were eliminated by modifications to the blade structure and fabrication method. Details of the fabrication method and the stress-ratio factors for the blades are presented.

NACA RM E56C16

EXPERIMENTAL INVESTIGATION OF INTERFERENCE EFFECTS OF LATERAL-SUPPORT STRUTS ON AFTERBODY PRESSURES AT MACH 1.9. John L. Klann and Ronald G. Huff. May 1956. 13p. diagrs., tab. (NACA RM E56C16)

A series of single and double unswept, lateral-support struts were tested at Mach 1.9 on a cone-cylinder body at zero angle of attack. All strut-body interference effects were small beyond a length of eight body diameters. However, a nonreflected shock wave due to the presence of the support struts at the tunnel walls did affect afterbody pressures. Reduction of the leading-edge strut angle alleviated this disturbance.

NACA RM E56D04

INJECTION PRINCIPLES FOR LIQUID OXYGEN AND HEPTANE USING TWO-ELEMENT INJECTORS. Marcus F. Heidmann. June 1956. 30p. diagrs., photos., tab. (NACA RM E56D04)

The data from the 400-pound-thrust heptane-oxygen rocket engine are compared with data obtained with single elements in a 200-pound-thrust engine. The results show that, with injection methods that both mix and atomize propellants, the performance was comparable to that of a single element. With other injection methods, performance was not appreciably altered by using two elements, except in the case of interference between spray patterns of the same propellant where performance decreased substantially. High-frequency combustion instability, frequently encountered with single element, did not occur with the two-element injectors.

NACA RM E56D13

EFFECT OF DESIGN OVER-ALL COMPRESSOR PRESSURE RATIO DIVISION ON ACCELERATION CHARACTERISTICS OF THREE HYPOTHETICAL TWO-SPOOL TURBOJET ENGINES. Richard E. Filippi and James F. Dugan, Jr. August 1956. 26p. diagrs. (NACA RM E56D13)

The engines, each with a compressor overall total-pressure ratio of 12 and a design inner-turbine-inlet temperature of 2500° R, were investigated at static sea-level conditions to determine the effect on transient performance of varying the design pressure ratio divisions 2-6, 3-4, and 4-3 between the outer and inner compressors. The transient considered was an acceleration from 40 to 100 percent design thrust. When the outer compressor of each engine reached design speed, the inner compressors were overspeeding, the maximum being only 1.7 percent over design mechanical speed. Acceleration times for the three engines were equal.

NACA RM E56D27a

INTERNAL PERFORMANCE CHARACTERISTICS OF SHORT CONVERGENT-DIVERGENT EXHAUST NOZZLES DESIGNED BY THE METHOD OF CHARACTERISTICS. H. George Krull and William T. Beale. July 1956. 17p. diagrs. (NACA RM E56D27a)

Internal performance data on a short exhaust nozzle designed by the method of characteristics were obtained over a range of pressure ratios from 1.5 to 22. The peak thrust coefficient was not affected by a shortened divergent section, but it occurred at lower pressure ratios due to reduction in expansion ratio. This nozzle contour based on characteristics solution gave higher thrust coefficients than a conical convergent-divergent nozzle of equivalent length. Abrupt-inlet sections permitted a reduction in nozzle length without a thrust-coefficient reduction.

NACA RM E56I25a

A STUDY OF INJECTION PROCESSES FOR LIQUID OXYGEN AND GASEOUS HYDROGEN IN A 200-POUND-THRUST ROCKET ENGINE. Carmon M. Auble. January 1957. 32p. diagrs., photos. (NACA RM E56I25a)

Characteristic velocities of six single-element injectors that separately varied propellant spreading and mixing were measured over a range of oxidant-fuel weight ratios of 2 to 7. Hydrogen inlet temperature was -320° F. Injectors that both mixed and spread the propellants had the highest characteristic-velocity efficiency. Spreading of either propellant produced about the same increment of efficiency. The increase in efficiency due to mixing was relatively small. With similar injectors, oxygen-hydrogen required about 0.2 to 0.5 of the combustor volume of oxygen-heptane for the same efficiency.

NACA RM E57E03

PROPELLANT VAPORIZATION AS A CRITERION FOR ROCKET-ENGINE DESIGN; EXPERIMENTAL EFFECT OF FUEL TEMPERATURE ON LIQUID-OXYGEN - HEPTANE PERFORMANCE. M. F. Heidmann. July 1957. 21p. diagrs., tabs. (NACA RM E57E03)

Characteristic exhaust velocity of a 200-pound-thrust rocket engine was evaluated for fuel temperatures of -90°, 40°, and 200° F with a spray formed by two impinging heptane jets reacting in a highly atomized oxygen atmosphere. Tests covered a range of mixture ratios and chamber lengths. The characteristic exhaust-velocity efficiency increased 2 percent for a 290° F increase in fuel temperature. This increase in performance can be compared with that obtained by increasing chamber length by about 1/2 inch. The result agrees with the fuel-temperature effect predicted from an analysis based on droplet-evaporation theory. Mixture ratio markedly affected characteristic exhaust-velocity efficiency, but total flow rate and fuel temperature did not.

NACA RM E57E13

INJECTION PRINCIPLES FOR LIQUID OXYGEN AND HEPTANE USING NINE-ELEMENT INJECTORS IN AN 1800-POUND-THRUST ROCKET ENGINE. Richard F. Neu. July 1957. 27p. diagrs., photos., tab. (NACA RM E57E13)

Characteristic velocity data were obtained from six 9-element injectors in an 1800-pound-thrust engine. The results are compared with data previously obtained from two-element injectors in a 400-pound-thrust engine to evaluate spray interference effects. The results paralleled closely the two-element injector results although the decrease in performance due to like propellant spray interference was about two-fifths that of the two-element study. High-frequency combustion instability, frequently encountered with single-element injectors but not present in two-element injectors, also did not occur with the nine-element injectors.

NACA RM E57E15

EXPLORATORY INVESTIGATION OF STATIC- AND BASE-PRESSURE INCREASES RESULTING FROM COMBUSTION OF ALUMINUM BOROHYDRIDE ADJACENT TO BODY OF REVOLUTION IN SUPERSONIC WIND TUNNEL. John S. Serafini, Robert G. Dorsch, and Edward A. Fletcher. October 1957. 49p. diagrs., photos., tabs. (NACA RM E57E15)

The pressure distribution, resulting from combustion of aluminum borohydride about a body of revolution, was experimentally investigated in a wind tunnel at a Mach number of 2.47. Stable and steady-state combustion runs of several seconds duration resulted in static-pressure increases of about 70 percent on the cylindrical surface. The base pressure increased from 1.37 inches of mercury prior to combustion to 4.98 inches of mercury during combustion.

DETERMINATION OF THE AERODYNAMIC CENTER AND ZERO-LIFT PITCHING-MOMENT COEFFICIENT OF THE WING-FUSELAGE COMBINATION BY MEANS OF TAIL-LOAD MEASUREMENTS IN THE MACH NUMBER RANGE FROM 0.37 TO 0.87. John P. Mayer, George M. Valentine, and Geraldine C. Mayer. July 11, 1950. 27p. diagrs., photos., tab. (NACA RM L50D10)

Flight measurements of aerodynamic tail loads have been made on the Douglas D-558-II airplane from which the variation with Mach number of the wing-fuselage aerodynamic center, the static-longitudinal-stability parameter $(\partial C_M/\partial C_L)_{WF}$, the tail load per g, and the zero-lift wing-fuselage pitching-moment coefficient have been determined up to a Mach number of 0.87.

LOAD DISTRIBUTIONS ASSOCIATED WITH CONTROLS AT SUPERSONIC SPEEDS. K. R. Czarnecki and Douglas R. Lord. May 1953. 21p. photo., diagrs. (NACA RM L53D15a)

The status of the control loads problem at the present time is discussed and some recent test results concerning the aerodynamic loads associated with various types of controls at supersonic speeds are presented. Experimental results are compared with theoretical predictions for unbalanced controls, for controls with varying amounts of balance, and for spoilers, on two- and three-dimensional wings.

NACA RM L53D29a

LOADS DUE TO FLAPS AND SPOILERS ON SWEPTBACK WINGS AT SUPERSONIC AND TRANSONIC SPEEDS. Alexander D. Hammond and F. E. West, Jr. June 1953. 17p. diagrs. (NACA RM L53D29a)

A summary is presented of available data of the loads on thin sweptback wings and their point of application which results from deflection of flaps and spoilers at high subsonic and transonic speeds. Presented also are the loads on a spoiler on a typical sweptback-wing configuration.

NACA RM L54C04

ROCKET-POWERED MODEL INVESTIGATION OF LIFT, DRAG, AND STABILITY OF A BODY-TAIL CONFIGURATION AT MACH NUMBERS FROM 0.8 TO 2.3 AND ANGLES OF ATTACK BETWEEN ±6.5°. Warren Gillespie, Jr., and Albert E. Dietz. April 1954. 42p. diagrs., photos., tabs. (NACA RM L54C04)

A missile configuration having a body of fineness ratio 16.6, an unswept horizontal tail of aspect ratio 2.7, and a highly swept vertical tail was aeropulsed continuously in pitch during free flight with and without a sustainer rocket motor operating. The Mach number range covered by the test was 0.8 to 2.3 and the model angle of attack did not exceed ±6.5°. Zero-lift-drag and drag-due-to-lift data were obtained during coasting flight of the model. Normal-force, pitching-moment, and static-stability data were obtained with and without the rocket motor thrusting. Analysis of the data indicated that cross coupling between pitching and yawing motions may have occurred during certain portions of the flight.

NACA RM L54C16

EXPERIMENTAL EFFECTS OF PROPULSIVE JETS AND AFTERBODY CONFIGURATIONS ON THE ZERO-LIFT DRAG OF BODIES OF REVOLUTION AT A MACH NUMBER OF 1.59. Carlos A. de Moraes and Albin M. Nowitzky. April 1954. 32p. diagrs., photos. (NACA RM L54C16)

The present investigation was made at a free-stream Mach number of 1.59 to compare the afterbody drags of a series of conical boattailed models at zero angle of attack. Afterbody drags were obtained for both the power-off and the power-on conditions. Power-on drags were obtained as a function of afterbody fineness ratio, jet pressure ratio and divergence, and jet Mach number.

NACA RM L54C17a

EFFECTS OF SPOILER AILERONS ON THE AERODYNAMIC LOAD DISTRIBUTION OVER A 45° SWEPTBACK WING AT MACH NUMBERS FROM 0.60 TO 1.03. Joseph M. Hallissy, Jr., F. E. West, Jr., and George Liner. May 1954. 162p. diagrs., tabs. (NACA RM L54C17a)

An investigation was conducted with 73-percent-semispan inboard-spoiler ailerons, having heights of 4 percent of the local wing chord and located along the 70-percent wing-chord line of a 45° sweptback-wing—fuselage combination. The wing had an aspect ratio of 3.98, a taper ratio of 0.61, and NACA 65A006 airfoil sections parallel to the plane of symmetry. Test configurations included upper- and lower-surface spoilers, with and without a gap through the wing behind the spoiler. Chordwise pressure-distribution data were obtained at seven spanwise stations at Mach numbers from 0.60 (Reynolds number, 5.1×10^6) to 1.03 (Reynolds number, 6.2×10^6) for an angle-of-attack range that usually extended to 20° or higher. The effects of upper- and lower-surface spoilers on chordwise pressure distributions, wing normal forces, wing span-load distributions, and positions of center of pressure are shown. Spoiler load distributions are also shown.

NACA RM L54D20

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE EFFECT OF ADDING VARIOUS COMBINATIONS OF MISSILES ON THE AERODYNAMIC CHARACTERISTICS OF SWEPTBACK AND UNSWEPT WINGS COMBINED WITH A FUSELAGE. H. Norman Silvers and William J. Alford, Jr. June 1954. 39p. diagrs., photo., tabs. (NACA RM L54D20)

An investigation was made at Mach numbers from 0.50 to about 0.94 of the effects of missiles attached in various combinations of two spanwise and two vertical locations on the longitudinal stability and performance characteristics of models with a 46.7° sweptback wing and a 3.5° sweptback wing combined with a fuselage.

NACA RM L54D27

TRANSONIC FLIGHT TEST OF A ROCKET-POWERED MODEL TO DETERMINE PROPULSIVE JET INFLUENCE ON THE CONFIGURATION DRAG. Carlos A. deMoraes. June 1954. 16p. diagrs., photo. (NACA RM L54D27)

The present investigation was conducted in the transonic Mach number range of 0.8 to 1.2. The Reynolds number based on body length varied from 23×10^6 to 43×10^6. The interference effects of the overexpanded propulsive jet were to decrease the boattail pressures (in the vicinity of the base) and the base pressure. At a Mach number of 1.075 the power-on drag was more than 24 percent higher than the power-off drag.

NACA RM L54D29

LOW-AMPLITUDE DAMPING-IN-PITCH CHARACTERISTICS OF TAILLESS DELTA-WING—BODY COMBINATIONS AT MACH NUMBERS FROM 0.80 TO 1.35 AS OBTAINED WITH ROCKET-POWERED MODELS. Charles T. D'Aiutolo. June 1954. 34p. diagrs., photos., tab. (NACA RM L54D29)

A flight test was conducted using three delta-wing—body combinations: an aspect-ratio-2 delta-wing—body combination with afterbody, an aspect-ratio-2 delta-wing—body combination with no afterbody, and an aspect-ratio-3 delta-wing—body combination with afterbody. All models incorporated NACA 63A006 airfoil sections. Data were obtained on the static and dynamic stability, drag characteristics, and the effects of aspect ratio on the damping in pitch between the Mach numbers of 0.80 and 1.35 corresponding to Reynolds number of 9×10^6 to 20×10^6. An application of the effect of dynamic instability on the performance of a full-scale airplane has been made from the data obtained from the flight-test models.

NACA RM L55C29

EXPLORATORY TESTS OF TRANSPIRATION COOLING OF A POROUS 8° CONE AT M = 2.05 USING NITROGEN GAS, HELIUM GAS, AND WATER AS THE COOLANTS. Leo T. Chauvin and Howard S. Carter. June 1955. 22p. diagrs., photos., tab. (NACA RM L55C29)

The effectiveness of transpiration cooling on an 8° total-angle porous cone is presented for various coolant flow rates of nitrogen gas, helium gas, and distilled water. The tests were made at a Mach number of 2.05 and Reynolds number of 8×10^6. The heat transfer with nitrogen gas was in agreement with theory. At the same flow rate, helium gas reduced the heat transfer more than nitrogen gas. Cooling with distilled water gave a large reduction in the average wall temperature.

NACA RM L55D11

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE EFFECTS OF VARIOUS UNDERWING EXTERNAL-STORE ARRANGEMENTS ON THE AERODYNAMIC CHARACTERISTICS OF A 1/16-SCALE MODEL OF THE DOUGLAS D-558-II RESEARCH AIRPLANE. H. Norman Silvers and Thomas J. King, Jr. July 1955. 59p. diagrs., photos., tab. (NACA RM L55D11)

An investigation of various external stores on a 1/16-scale model of the Douglas D-558-II research airplane has been made in the Langley high-speed 7- by 10-foot tunnel at Mach numbers from 0.40 to 0.96. All stores were located at the 0.61-semispan station. Three store sizes were investigated for a shape having a short cylindrical section between the forebody and the afterbody. Two store sizes were investigated for a shape having a long cylindrical center body. Pylon thicknesses of 7.6-, 6.2-, and 4.2-percent pylon chord were used with one of the stores.

NACA RM L55I21

FLIGHT MEASUREMENTS OF SECTION EFFICIENCY, THRUST, AND POWER OF A SUPERSONIC-TYPE PROPELLER AT MACH NUMBERS TO 0.9. Jerome B. Hammack and Thomas C. O'Bryan. January 1956. 38p. diagrs., photos., tab. (NACA RM L55I21)

Flight tests have been made on a supersonic-type propeller designed for a forward Mach number of 0.95 and advance ratio of 2.2. Power and thrust distributions, and section efficiency were determined over a range of forward Mach numbers to 0.9 in level flight. At an advance ratio of 2.2 and a forward Mach number of 0.9, blade section efficiencies were measured to be a maximum of 83 percent. Measured thrust distributions are smooth and uniform; such distributions are indicative of efficient operation. Power distributions which show section power absorption are also presented.

NACA RM L56C16

EFFECT OF WING CAMBER AND TWIST AT MACH NUMBERS FROM 1.4 TO 2.1 ON THE LIFT, DRAG, AND LONGITUDINAL STABILITY OF A ROCKET-POWERED MODEL HAVING A 52.5° SWEPTBACK WING OF ASPECT RATIO 3 AND INLINE TAIL SURFACES. Warren Gillespie, Jr. May 1956. 29p. diagrs., photos., tabs. (NACA RM L56C16)

The effect of wing camber and twist on the aerodynamic performance of a free-flight rocket-powered model was investigated at supersonic Mach numbers. The configuration tested had a 52.5° sweptback wing of aspect ratio 3, a body of fineness ratio 16.9, and inline tail surfaces. The warped wing was designed to have low drag at a wing lift coefficient of 0.3 and a Mach number of 1.46. Drag polars, normal force, pitching moment, static longitudinal stability, and wash effects at the tail were obtained. Comparisons are made with data from a similar model that had a flat wing.

NACA RM L56C21

JET EFFECTS ON BASE AND AFTERBODY PRESSURES OF A CYLINDRICAL AFTERBODY AT TRANSONIC SPEEDS. James M. Cubbage, Jr. May 1956. 50p. diagrs., photos. (NACA RM L56C21)

An investigation of the effects of jet nozzle geometry, size of base annulus, and base bleed upon the base and afterbody pressures of a cylindrical afterbody at transonic speeds has been conducted. Sonic and supersonic conical nozzles with jet-to-base diameter ratios from 0.25 to 0.85 were investigated with a cold jet at jet total-pressure ratios up to approximately 8.0 through a Mach number range from 0.6 to 1.25. Base pressure coefficients of about -0.55 were measured for the sonic nozzles at a Mach number of 1 or greater. The jet-to-base diameter ratio had a substantial effect on the base pressure obtained on the cylindrical afterbody of this investigation. Base bleed was beneficial in increasing the base pressure under certain conditions but had little or no effect at certain other conditions.

NACA RM L56C22

INVESTIGATION AT TRANSONIC SPEEDS OF THE EFFECTS OF INLET LIP STAGGER ON THE INTERNAL-FLOW CHARACTERISTICS OF AN UNSWEPT SEMIELLIPTICAL AIR INLET. Gene J. Bingham and Charles D. Trescot, Jr. May 1956. 31p. diagrs., photos., tab. (NACA RM L56C22)

An investigation has been made in the Langley transonic blowdown tunnel to study the effects of variations in inlet lip stagger from 0° to 60° on the internal-flow characteristics of an unswept semielliptical scoop-type air-inlet model without boundary-layer control. Tests were made at Mach numbers of 1.0, 1.2, and 1.4 through a mass-flow ratio range from about 0.3 to 0.9 at an angle of attack of 0°. Increases in total-pressure recovery with decreasing mass-flow ratio were effected for the 30° configuration at Mach numbers of 1.2 and 1.4. The maximum recovery (near normal shock) was obtained with the 30° stagger inlet at a mass-flow ratio of 0.63 ($M_O = 1.4$).

NACA RM L56D03

LOW-SPEED WIND-TUNNEL RESULTS FOR A THIN ASPECT-RATIO-1.85 POINTED-WING—FUSELAGE MODEL WITH DOUBLE SLOTTED FLAPS. Albert E. Brown. July 1956. 31p. diagrs., tabs. (NACA RM L56D03)

Results are presented of a wind-tunnel investigation at low speeds of a thin aspect-ratio-1.85 pointed-wing—fuselage model equipped with double slotted flaps, including the effects of a straight and a delta horizontal tail on the static longitudinal stability and the effect of a delta vertical tail on the static lateral stability. Flap effectiveness increased with increase of flap deflection up to 52.5°. With a flap deflection of 52.5° the lift coefficient at an angle of attack of 0° was 0.66 and a maximum lift coefficient was 1.53. Most of the lift coefficient increment at an angle of attack of 0° held throughout the angle-of-attack range to near stall. Satisfactory location of the straight and delta horizontal tails was rearward and below the wing chord line extended. A delta vertical tail provided static directional stability of the model except at high lift coefficients and generally increased effective dihedral.

NACA RM L56D06

A SUMMARY OF NACA RESEARCH ON THE STRENGTH AND CREEP OF AIRCRAFT STRUCTURES AT ELEVATED TEMPERATURES. Richard R. Heldenfels and Eldon E. Mathauser. (Presented at Symposium on High-Speed Aerodynamics and Structures sponsored jointly by Air Research and Development Command, Bell Aircraft Corporation, Cornell Aeronautical Laboratory, and University of Buffalo, January 18-20, 1956, Buffalo, New York.) May 1956. 22p. diagrs. (NACA RM L56D06)

This paper summarizes some NACA research on the strength and creep of aircraft structural elements and components at elevated temperatures. Experimental data for aluminum-alloy columns, plates, stiffened panels, and multiweb box beams are presented for temperatures up to 600° F and compared with results predicted from materials data. Methods are described for predicting maximum strength from material stress-strain curves and creep lifetime from isochronous stress-strain curves. Some observations on the probable effect of creep on the design of aircraft structures are also included to illustrate the influence of design criteria on the weight of aircraft structures at elevated temperatures.

NACA RM L56D13

SOME EFFECTS OF WING FENCES ON THE LATERAL STABILITY DERIVATIVES OF A 60° DELTA WING OSCILLATING CONTINUOUSLY IN YAW. Donald R. Riley. July 1956. 29p. diagrs., photos., tab. (NACA RM L56D13)

From a wind-tunnel investigation made at low speed, results are presented which indicate some of the effects of wing fences on the lateral stability derivatives of a 60° delta-wing model oscillating continuously in yaw. Measurements were obtained for the rolling-moment and yawing-moment components in phase and out of phase with the model motion. The results indicate some of the effects of fence geometric characteristics, reduced frequency, oscillation amplitude, and angle of attack. The addition of wing fences provided large reductions in the magnitudes of the out-of-phase derivatives at high angles of attack and low reduced frequency by reducing the amount of separated flow on the wing surface. In addition, increases were obtained in the magnitudes of the in-phase derivatives.

NACA RM L56D19

THE EFFECT OF EXTERNAL STIFFENING RIBS ON THE ROLLING POWER OF AILERONS ON A SWEPT WING. Emily W. Stephens. October 1956. 15p. diagrs., photo., tab. (NACA RM L56D19)

An investigation, using rocket-powered models, was made to determine some effects on rolling effectiveness and drag of external ribs on swept wings. The Mach number range covered was from 0.6 to 1.6. The test wings were swept 45° at the quarter chord and had aspect ratios of 4.0, taper ratios of 0.6, NACA 65A006 airfoil sections parallel to the free stream, and one-half-span outboard flap-type ailerons of 30 percent chord. The results of the tests showed that stiffening the wings by the addition of fences increased the zero-lift rolling effectiveness and the reversal Mach number for the more flexible wings. It was indicated that the aerodynamic effects of adding fences would be small; however, a 10-percent increase in total drag coefficient was noted.

NACA RM L56D20a

FLIGHT MEASUREMENTS OF THE VIBRATORY BENDING AND TORSION STRESS ON A SUPERSONIC-TYPE PROPELLER FOR FLIGHT MACH NUMBERS UP TO 0.95. Thomas C. O'Bryan. July 1956. 22p. diagrs., photos., tab. (NACA RM L56D20a)

Vibratory stress measurements have been obtained in flight on a supersonic-type propeller for forward Mach numbers up to 0.95. Measured vibratory bending stresses were low and almost pure once-per-revolution stresses for Mach numbers up to approximately 0.82. There was no evidence of flutter during the flight program.

NACA RM L56D26

COMPARISON WITH THEORY OF LANDING IMPACTS OF A MODEL OF A SEAPLANE INCORPORATING A HYDRO-SKI WITH AND WITHOUT A SHOCK ABSORBER. Edward L. Hoffman. July 1956. 30p. diagrs., photo., tabs. (NACA RM L56D26)

Theoretical computations based on the application of planing data to impact conditions were compared with experimental data of calm- and rough-water landing impacts of a dynamic model of a seaplane incorporating a flat-bottom hydro-ski that could be mounted

DECLASSIFIED NACA RESEARCH REPORTS

on a rigid strut and on a shock-absorber strut so that the ski translated normal to its keel without changing trim. A method was developed for obtaining an equivalent wave slope on which to base rough-water computations.

NACA RM L57A09

MEASUREMENT OF STATIC PRESSURE ON AIRCRAFT. William Gracey. April 1957. ii, 70p. diagrs. (NACA RM L57A09)

Existing data on the measurement of static pressure by means of static-pressure tubes and fuselage vents at subsonic, transonic, and supersonic speeds are presented. Static-pressure errors are given for isolated tubes and vents and for installations ahead of the fuselage nose, wing tip, and vertical tail fin, and on the fuselage. Various methods of calibrating installations in flight are briefly discussed.

NACA RM L57A30

EXPERIMENTAL DETERMINATION AT SUBSONIC SPEEDS OF THE OSCILLATORY AND STATIC LATERAL STABILITY DERIVATIVES OF A SERIES OF DELTA WINGS WITH LEADING-EDGE SWEEP FROM 30° TO 86.5°. William Letko. April 1957. 38p. diagrs., photos., tab. (NACA RM L57A30)

The static lateral stability of six delta wings was determined at subsonic speeds and, in addition, two of the wings having 82.5° and 75° sweep of the leading edge were oscillated in yaw about their vertical axis to determine the effects of frequency and amplitude on the combination lateral stability derivatives resulting from this motion. The results generally showed that large changes in the derivatives occurred with changes of frequency and amplitude at high angles of attack.

NACA RM L57E20

FLIGHT INVESTIGATION OF A SUPERSONIC PROPELLER ON A PROPELLER RESEARCH VEHICLE AT MACH NUMBERS TO 1.01. Jerome B. Hammack, Max C. Kurbjun, and Thomas C. O'Bryan. July 1957. 43p. diagrs., photos. (NACA RM L57E20)

The NACA propeller research vehicle, the McDonnell XF-88B airplane, is described. Results of flight investigation made with this vehicle to determine the aerodynamic characteristics of a supersonic propeller at the design Mach number of 0.95 and the design advance ratio of 2.2 are presented. At these design conditions the propeller efficiency was determined to be 79 percent. At the maximum test Mach number (M = 1.01) the propeller efficiency was measured to be 78 percent.

NACA RM L57F07

EFFECT OF FREQUENCY OF SIDESLIPPING MOTION ON THE LATERAL STABILITY DERIVATIVES OF A TYPICAL DELTA-WING AIRPLANE. Jacob H. Lichtenstein and James L. Williams. September 1957. 46p. diagrs., photos., tabs. (NACA RM L57F07)

An investigation has been made in the Langley stability tunnel at low speeds to determine the effect of frequency of sideslipping motion on the lateral stability derivatives of a typical 60° delta-wing airplane configuration. The results, for the various configurations tested, show that changes in the frequency of oscillation at low angles of attack had an appreciable effect on the yawing-moment derivatives and a negligible effect on the rolling-moment derivatives of the complete-model configuration and a negligible effect on the derivatives for the other configuration. Both the yawing- and rolling-moment derivatives underwent very large changes in magnitude because of the oscillatory motion at high angles of attack. Leading-edge radius had a pronounced bearing on the oscillatory stability derivatives for the wing alone in that a decrease in leading-edge radius considerably accentuated the effects due to oscillatory motion. The use of oscillatory sideslip derivatives instead of steady-state derivatives resulted in an increase in the calculated damping and stability for a typical delta-wing airplane at the high angles of attack.

NACA RM L57H02

A PRELIMINARY INVESTIGATION OF METHODS FOR IMPROVING THE PRESSURE-RECOVERY CHARACTERISTICS OF VARIABLE-GEOMETRY SUPERSONIC-SUBSONIC DIFFUSER SYSTEMS. Lowell E. Hasel and Archibald R. Sinclair. October 1957. 57p. diagrs., photos. (NACA RM L57H02)

An investigation has been initiated to study methods for improving the pressure-recovery characteristics of two-dimensional variable-geometry supersonic-subsonic diffuser systems. The pressure recovery of the basic configuration which had a relatively long supersonic diffuser varied from 0.71 to 0.21 over a Mach number range from 2.50 to 4.75. Incorporation of an injector at the end of the supersonic diffuser resulted in recoveries which varied from 0.65 to 0.56 over a Mach number range from 2.95 to 4.70. The results indicate that considerable improvement in the performance of new or existing supersonic wind tunnels can be obtained by modifying the diffuser.

NACA Rept. 1300

BASIC CONSIDERATIONS IN THE COMBUSTION OF HYDROCARBON FUELS WITH AIR. Propulsion Chemistry Division. Edited by Henry C. Barnett and Robert R. Hibbard. Chap. I: ATOMIZATION AND EVAPORATION OF LIQUID FUELS. Charles C. Graves and Donald W. Bahr. Chap. II: FLOW AND MIXING PROCESSES IN COMBUSTION CHAMBERS. Wilfred E. Scull and William R. Mickelsen. Chap. III: IGNITION AND FLAMMABILITY OF HYDROCARBON FUELS. Frank E. Belles and Clyde C. Swett. Chap. IV: LAMINAR FLAME PROPAGATION. Gordon L. Dugger, Dorothy M. Simon, and Melvin Gerstein. Chap. V: TURBULENT FLAMES. Melvin Gerstein and Gordon L. Dugger. Chap. VI: FLAME STABILIZATION. Gordon L. Dugger and Melvin Gerstein. Chap. VII: DIFFUSION FLAMES. Richard S. Brokaw and Melvin Gerstein. Chap. VIII: OSCILLATIONS IN COMBUSTORS. Perry L. Blackshear, Jr., and Warren D. Rayle. Chap. IX: SMOKE AND COKE FORMATION IN THE COMBUSTION OF HYDROCARBON-AIR MIXTURES. Rose L. Schalla and Robert R. Hibbard. 1957. xi, 259p. diagrs., photos., tabs. (NACA Rept. 1300)

Basic combustion research is collected, collated, and interpreted as it applies to flight propulsion. The following fundamental processes are treated in separate chapters: atomization and evaporation of liquid fuels, flow and mixing processes in combustion chambers, ignition and flammability of hydrocarbon fuels, laminar flame propagation, turbulent flames, flame stabilization, diffusion flames, oscillations in combustors, and smoke and coke formation in the combustion of hydrocarbon-air mixtures. Theoretical background, basic experimental data, and practical significance to flight propulsion are presented.

NACA Rept. 1314

SUMMARY OF SCALE-MODEL THRUST-REVERSER INVESTIGATION. John H. Povolny, Fred W. Steffen, and Jack G. McArdle. 1957. ii, 14p. diagrs., photos. (NACA Rept. 1314. Supersedes TN 3664)

This report summarizes the results of a scale-model thrust-reverser investigation. Three basic types of thrust reversers, target, tail-pipe cascade, and ring cascade, were investigated. All three were found to have satisfactory reverse-thrust performance and thrust-modulation characteristics.

NACA Rept. 1319

INDUCED VELOCITIES NEAR A LIFTING ROTOR WITH NONUNIFORM DISK LOADING. Harry H. Heyson and S. Katzoff. 1957. iii, 88p. diagrs., photos., tab. (NACA Rept. 1319. Supersedes TN 3690; TN 3691)

A method is given for converting known uniformly loaded rotor induced velocities to correspond with arbitrary axisymmetric nonuniform disk load distributions. Numerical results for two specific distributions are given in chart form. Symmetry relations and relations between radial disk loading and wake velocities are developed. Experimental flow measurements are presented and compared with theory. Reasonable agreement is shown in the forward part of the flow when nonuniform loading is assumed, but far behind the rotor the flow is more like that of a wing.

NACA Rept. 1321

THEORETICAL CALCULATION OF THE POWER SPECTRA OF THE ROLLING AND YAWING MOMENTS ON A WING IN RANDOM TURBULENCE. John M. Eggleston and Franklin W. Diederich. 1957. ii, 19p. diagrs., tabs. (NACA Rept. 1321. Supersedes TN 3864.)

An analytical solution is derived for the power spectral density of the rolling- and yawing-moment coefficients of a wing subjected to random isotropic atmospheric turbulence. The theory considers the random variations of the turbulence in the spanwise as well as the flight-path direction. Horizontal, vertical, and side gust components are considered. Plots of the power spectra are presented.

NACA Rept. 1323

INVESTIGATION OF THE LAMINAR AERODYNAMIC HEAT-TRANSFER CHARACTERISTICS OF A HEMISPHERE-CYLINDER IN THE LANGLEY 11-INCH HYPERSONIC TUNNEL AT A MACH NUMBER OF 6.8. Davis H. Crawford and William D. McCauley. 1957. ii, 21p. diagrs., photos., tab. (NACA Rept. 1323. Supersedes TN 3706)

The aerodynamic heat transfer of a nonisothermal hemisphere-cylinder has been investigated at a Mach number of 6.8 and Reynolds numbers from 0.14×10^6 to 1.06×10^6 based on diameter and free-stream conditions. The experimental heat transfer was slightly less than that predicted by the Stine and Wanlass theory (NACA TN 3344) for an isothermal surface. For stations within 45° of the stagnation point the heat transfer could be correlated by a single relation between local Stanton and local Reynolds numbers.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1326

FLIGHT AND ANALYTICAL METHODS FOR DETERMINING THE COUPLED VIBRATION RESPONSE OF TANDEM HELICOPTERS. John E. Yeates, Jr., George W. Brooks, and John C. Houbolt. 1957. iv, 31p. diagrs., photo., tabs. (NACA Rept. 1326. Supersedes TN 3852; TN 3849)

A discussion of flight-test and analysis methods for some selected helicopter vibration studies is presented. The use of a mechanical shaker in flight to determine the structural response is reported. Some results are presented to show the coupled response of a helicopter in flight for two different blade configurations. In addition a method is presented for calculating the natural coupled frequencies and mode shapes of vertical vibrations of tandem helicopters; certain forced excitations are also considered. Frequency response functions of cockpit deflection for various applied oscillating forces are given.

NACA Rept. 1329

FAR NOISE FIELD OF AIR JETS AND JET ENGINES. Edmund E. Callaghan and Willard D. Coles. 1957. ii, 18p. diagrs., photos. (NACA Rept. 1329. Supersedes TN 3590; TN 3591)

The effect of nozzle-exit shape was studied using a small (4-in. diam.) air jet. Circular, square, rectangular, and elliptical convergent nozzles and convergent-divergent and plug nozzles were investigated. At low jet pressure ratios (less than 2.2) the effect of nozzle shape on the sound field was negligible. At high jet pressure ratios all the nozzles exhibited discrete-frequency noises associated with shock formations in the jet. The convergent-divergent nozzle showed an elimination of such noises at its design pressure ratio. The acoustic power radiated by the engines and air jet was correlated by the Lighthill parameter. The free-field spectral distribution of the sound power was in good agreement for both engine and air jet.

NACA Rept. 1333

ATTENUATION IN A SHOCK TUBE DUE TO UNSTEADY-BOUNDARY-LAYER ACTION. Harold Mirels. 1957. iii, 19p. diagrs., tab. (NACA Rept. 1333. Supersedes TN 3278)

A method is presented for obtaining the attenuation of a shock wave in a shock tube due to the unsteady boundary layer along the shock-tube walls. It is assumed that the boundary layer is thin relative to the tube diameter and induces one-dimensional longitudinal pressure waves whose strength is proportional to the vertical velocity at the edge of the boundary layer. The method is shown to be in reasonably good agreement with existing experimental data.

NACA RM 58B11

LOCAL ISOTROPY IN TURBULENT SHEAR FLOW. Stanley Corrsin, Johns Hopkins University. May 1958. 15p. diagr. (NACA RM 58B11)

The mean strain rate in turbulent shear flow must tend to make the structure anisotropic in all parts of the spectrum. The argument is presented that, if the spectral energy transfer process destroys orientation, the Kolmogoroff notion of local isotropy can still be justified in spectral regions where the local transfer time is shorter than the characteristic time of the gross shear strain.

NACA RM E58A21

THEORETICAL PERFORMANCE OF LIQUID AMMONIA WITH LIQUID OXYGEN AS A ROCKET PROPELLANT. Sanford Gordon and Alan R. Glueck. May 1958. 84p. diagrs., tabs. (NACA RM E58A21)

Data were calculated for both equilibrium and frozen composition for chamber pressures of 300 and 600 lb/sq in. abs, pressure ratios from 1 to 1500, and oxidant-fuel ratios from 0.564 to 7.046. Parameters include specific impulse, specific impulse in vacuum, combustion and exit temperature, molecular weight, molecular-weight derivatives, characteristic velocity, coefficient of thrust, ratio of nozzle-exit area to throat area, specific heat at constant pressure, isentropic exponent, viscosity, thermal conductivity, Mach number, and equilibrium gas compositions. Maximum specific impulse for a chamber pressure of 600 lb/sq in. abs and an exit pressure of 1 atm (pressure ratio, 40.827) is 278.7 and 269.3 assuming equilibrium and frozen composition, respectively.

NACA RM E58B20

THEORETICAL ROCKET PERFORMANCE OF LIQUID METHANE WITH SEVERAL FLUORINE-OXYGEN MIXTURES ASSUMING FROZEN COMPOSITION. Sanford Gordon and Michael E. Kastner. May 1958. 44p. diagrs., tabs. (NACA RM E58B20)

Data were calculated for a chamber pressure of 600 pounds per square inch absolute, fluorine in oxidant from 0 to 100 percent, pressure ratios of 1 to 300, and a range of equivalence ratios. Parameters included are specific impulse, combustion and exit temperatures, molecular weight, characteristic velocity, coefficient of thrust, area ratio, specific heat, isentropic exponent, viscosity, thermal conductivity, and combustion compositions.

CURRENT NACA RESEARCH REPORTS

NACA TN 3924

DISCHARGE COEFFICIENTS FOR COMBUSTOR-LINER AIR-ENTRY HOLES. II - FLUSH RECTANGULAR HOLES, STEP LOUVERS, AND SCOOPS. Ralph T. Dittrich. April 1958. 56p. diagrs., tab. (NACA TN 3924)

Experimental discharge coefficients for various types of combustor-liner air-entry holes are presented as a function of a dimensionless flow parameter. In general, scoops and step louvers have higher discharge coefficients and wider flow ranges than flush holes. The effects of size or shape of a given type of hole are small. The proximity of multiple flush holes or the wall inclination of a convergent duct has a negligible effect on discharge coefficient.

NACA TN 4226

ANALYSIS OF HARMONIC FORCES PRODUCED AT HUB BY IMBALANCES IN HELICOPTER ROTOR BLADES. M. Morduchow and A. Muzyka, Polytechnic Institute of Brooklyn. April 1958. 37p. diagrs. (NACA TN 4226)

General explicit expressions are derived for the harmonic forces produced at the hub by an n-bladed unbalanced helicopter rotor. Imbalances due to property differences among the blades and to nonuniform spacing between the blades are considered. Numerical examples are given throughout to illustrate the order of magnitude of the results. For convenient reference, an analysis of the forces transmitted to the hub by a balanced rotor of n blades is also given.

NACA TN 4228

EFFECTS OF FIXING BOUNDARY-LAYER TRANSITION FOR AN UNSWEPT-WING MODEL AND AN EVALUATION OF POROUS TUNNEL-WALL INTERFERENCE FOR MACH NUMBERS FROM 0.60 TO 1.40. Louis S. Stivers, Jr., and Garth W. Lippmann. April 1958. 37p. diagrs. (NACA TN 4228)

Tests have been made in the Ames 2- by 2-foot transonic wind tunnel to determine the aerodynamic effects of fixing boundary-layer transition in a forward location on two unswept-wing models which differed only in size. The models had wings of aspect ratio 3.09 with sharp leading edges. The tests were made at Mach numbers from 0.60 to 1.40 and at Reynolds numbers from 1.5 to 3.45 million. The fixed-transition data were utilized to evaluate the interference of the porous walls of the Ames 2- by 2-foot transonic wind tunnel. The results demonstrated that the model size indicated to be necessary for small wall interference in NACA RM A55I21 is incorrect.

NACA TN 4235

OBSERVATIONS OF TURBULENT-BURST GEOMETRY AND GROWTH IN SUPERSONIC FLOW. Carlton S. James. April 1958. (i), 85p. diagrs., photos., tab. (NACA TN 4235)

Some aspects of the mechanics of boundary-layer transition have been deduced from a study of shadowgraphs of free-flight models at free-stream Mach numbers between 2.7 and 10. That part of the transition process between the first appearance of turbulence vortices and the end result of continuously turbulent flow is found to occur in supersonic flow in a manner closely similar to its observed occurrence in subsonic flow. Minute spots, or bursts, of turbulence form near the leading edge and are swept aft. The rates at which these bursts form and grow are found to vary gradually with Mach number, unit Reynolds number, and surface roughness.

NACA TN 4240

SOME MEASUREMENTS OF AERODYNAMIC FORCES AND MOMENTS AT SUBSONIC SPEEDS ON A RECTANGULAR WING OF ASPECT RATIO 2 OSCILLATING ABOUT THE MIDCHORD. Edward Widmayer, Jr., Sherman A. Clevenson, and Sumner A. Leadbetter. May 1958. 45p. diagrs., tabs. (NACA TN 4240. Supersedes RM L53F19)

Results are presented for a range of Mach number from 0.15 to 0.81, a range of reduced frequency from 0.15 to 1.32, and a range of Reynolds number from 0.60×10^6 to 9.21×10^6. A comparison of the measured aerodynamic forces and moments is made with some available published data. Comparisons are also made between the measured data and theoretical incompressible-flow coefficients obtained from the aspect-ratio theory of Reissner, the aspect-ratio theory of Lawrence and Gerber, and the two-dimensional-flow theory. Some experimental results pertaining to the influence of wind-tunnel-wall effects on nonsteady aerodynamic measurement are included.

NACA TN 4241

AN APPROXIMATE METHOD FOR DESIGN OR ANALYSIS OF TWO-DIMENSIONAL SUBSONIC-FLOW PASSAGES. E. Floyd Valentine. April 1958. 38p. diagrs., photo. (NACA TN 4241)

A method is developed for the design and analysis of two-dimensional subsonic-flow passages with isentropic nonviscous flow. The method is based on the relation between the pressure change across a stream tube and the centrifugal force resulting from the curvature of the flow. Precomputed charts can be drawn which eliminate subsequent calculation for a given upstream Mach number. The method is limited by the accuracy with which the radius of curvature of the streamlines can be determined.

CURRENT NACA RESEARCH REPORTS

NACA TN 4242

GENERAL SOLUTIONS FOR FLOW PAST SLENDER CAMBERED WINGS WITH SWEPT TRAILING EDGES AND CALCULATION OF ADDITIONAL LOADING DUE TO CONTROL SURFACES. E. B. Klunker and Keith C. Harder. May 1958. 55p. diagrs. (NACA TN 4242)

The slender-wing-type analysis is used to obtain general expressions for the surface pressure, lift, and rolling moment for cambered wings with swept trailing edges. These results are specialized to give the additional loading due to the deflection of trailing-edge control surfaces. The loading due to twist is also obtained for one particular form of twist.

NACA TN 4247

STUDY OF GROUND-REACTION FORCES MEASURED DURING LANDING IMPACTS OF A LARGE AIRPLANE. Albert W. Hall, Richard H. Sawyer, and James M. McKay. May 1958. 40p. diagrs., photo., tabs. (NACA TN 4247. Supersedes RM L55E12c)

Tests were conducted on a large bomber-type airplane to determine the ground-reaction forces imposed on the main landing gear under actual landing conditions. Data were obtained from 30 landings made at vertical velocities up to 8.4 feet per second and forward ground speeds from 81.0 to 119.5 knots. Vertical, drag, and side forces are presented. Results are presented of the effect of vertical velocity at contact on the vertical force and the variations of coefficient of friction with slip ratio during spin-up for both wet and dry concrete surfaces. A limited amount of side-force data indicating the nature of side-force variation with drift angle and vertical force is presented.

NACA TN 4248

SUMMARY OF EXPERIMENTAL HEAT-TRANSFER MEASUREMENTS IN TURBULENT FLOW FOR A MACH NUMBER RANGE FROM 0.87 TO 5.05. Maurice J. Brevoort and Barbara D. Arabian. May 1958. 43p. diagrs., photos., tab. (NACA TN 4248)

An axially symmetric annular nozzle was used to obtain essentially flat-plate data on turbulent heat-transfer coefficients and temperature-recovery factors. The test results of this paper are for Mach numbers 0.87, 1.62, 2.06, 3.03, 3.90, and 5.05 and for a Reynolds number range of 1×10^6 to 9.5×10^8. These results are presented in the form of Stanton number and recovery factor as a function of Reynolds number. The Stanton number shows a systematic variation with Mach number. The recovery factor appears to be independent of the Mach number in the range of these tests. Both Stanton number and recovery factor show a decrease with an increase in Reynolds number.

NACA TN 4251

AN EXPERIMENTAL INVESTIGATION OF WAKE EFFECTS ON HYDRO-SKIS. Ellis E. McBride and Lloyd J. Fisher. May 1958. 34p. diagrs., photos., tab. (NACA TN 4251)

Two combinations of hydro-skis were tested: two hydro-skis in tandem and three hydro-skis arranged with a single front hydro-ski. The results show that the rear hydro-ski in a tandem arrangement could have large increases in lift coefficient and small improvements in lift-drag ratio compared with a hydro-ski in undisturbed water over a limited speed range. The two rear hydro-skis in a three-hydro-ski arrangement would tend to have losses in efficiency compared with hydro-skis in undisturbed water, but the losses could apparently be prevented by carefully selecting the spacing.

NACA TN 4254

FLIGHT INVESTIGATION OF EFFECTS OF RETREATING-BLADE STALL ON BENDING AND TORSIONAL MOMENTS ENCOUNTERED BY A HELICOPTER ROTOR BLADE. LeRoy H. Ludi. May 1958. 23p. diagrs., photo. (NACA TN 4254)

The results of the investigation indicated that blade stall can produce large increases in periodic blade moments during high-speed flight and pull-up maneuvers. The results also indicated that the higher harmonics can contribute as much as the lower harmonics to increased vibration and increased periodic control loads in the highly stalled condition.

NACA TN 4261

ACOUSTIC, THRUST, AND DRAG CHARACTERISTICS OF SEVERAL FULL-SCALE NOISE SUPPRESSORS FOR TURBOJET ENGINES. Carl C. Ciepluch, Warren J. North, Willard D. Coles, and Robert J. Antl. April 1958. 48p. diagrs., photos. (NACA TN 4261)

An experimental investigation was conducted with an engine in the 10,000-pound-thrust class. The acoustic study was made with an outdoor thrust stand. Acoustic data are presented in terms of sound directionality, spectrum, and sound power. Aerodynamic properties of the suppressors were evaluated over a range of Mach numbers up to 0.5 in an altitude wind tunnel. The most efficient configurations from both acoustic and propulsive thrust considerations were a two-position mixing nozzle with ejector and a 12-lobe nozzle. At a Mach number of 0.5 the respective propulsive thrust losses were about 1 and 3 percent. Calculations indicate that these two configurations would reduce the noise heard during takeoff by 5 or 6 decibels.

CURRENT NACA RESEARCH REPORTS

NACA TN 4263

EFFECT OF PRIOR AIR FORCE OVERTEMPERATURE OPERATION ON LIFE OF J47 BUCKETS EVALUATED IN A SEA-LEVEL CYCLIC ENGINE TEST. Robert A. Signorelli, James R. Johnston, and Floyd B. Garrett. April 1958. 41p. diagrs., photos., tabs. (NACA TN 4263)

Buckets of S-816 alloy overtemperatured in service operation were evaluated in laboratory and engine tests. Some buckets were tested in the as-overtemperatured condition while others were heat-treated prior to testing. Results indicated that overtemperatured buckets did not fracture in abnormally short operating times, although life in stress-rupture tests was reduced. Cracks, particularly on the leading edge, developed after short operating times but did not propagate to fracture during several hundred hours of operation.

NACA TN 4265

COMPOSITION AND THERMODYNAMIC PROPERTIES OF AIR IN CHEMICAL EQUILIBRIUM. W. E. Moeckel and Kenneth C. Weston. April 1958. 39p. diagrs. (NACA TN 4265)

Charts have been prepared relating the thermodynamic properties of air in chemical equilibrium for temperatures to 15,000° K and for pressures from 10^{-5} to 10^{+4} atmospheres. Also included are charts showing the composition of air, the isentropic exponent, and the speed of sound. These charts are based on thermodynamic data calculated by the National Bureau of Standards.

NACA TN 4267

PRELIMINARY SURVEY OF PROPULSION USING CHEMICAL ENERGY STORED IN THE UPPER ATMOSPHERE. Lionel V. Baldwin and Perry L. Blackshear. Appendix D: HEAT TRANSFER AND FRICTION DRAG. James F. Schmidt. May 1958. 73p. diagrs., tabs. (NACA TN 4267)

Ram-jet cycles that use the chemical energy of dissociated oxygen for propulsion in the ionosphere are presented. After a review of the properties and compositions of the upper atmosphere, the external drag, recombination kinetics, and aerodynamic-heating problems of an orbiting ram jet are analyzed. The study indicates that the recombination ram jet might be useful for sustaining a satellite at an altitude of about 60 miles. Atmospheric composition and recombination-rate coefficients were too uncertain for more definite conclusions. The ram jet is a marginal device even in the optimistic view.

NACA TN 4268

DROPLET IMPINGEMENT AND INGESTION BY SUPERSONIC NOSE INLET IN SUBSONIC TUNNEL CONDITIONS. Thomas F. Gelder. May 1958. 56p. diagrs., photos. (NACA TN 4268)

The amount of water in cloud droplet form ingested by a full-scale supersonic nose inlet with conical center body was measured. Local and total water impingement rates on the cowl and center-body surfaces were also obtained. All measurements were made with a dye-tracer technique. Inlet angles of attack of 0° and 4.2°, droplet diameters from 11 to 20 microns, and ratios of inlet to free-stream velocity from 0.4 to 1.8 were studied. Measurements were confined to a free-stream Mach number of 0.237 and are extendable to other subsonic speeds by dimensionless impingement parameters.

NACA TN 4269

TRANSONIC DRAG OF SEVERAL JET-NOISE SUPPRESSORS. Warren J. North. April 1958. 34p. diagrs., photos. (NACA TN 4269)

One-fifth scale suppressors were tested at Mach numbers from 0.65 to 1.10 over a range of nozzle pressure ratios. Total and component drag coefficients are presented for the various models. Drag increases due to the suppressors are presented in terms of net thrust. Propulsive-thrust losses were calculated, and the results were converted into aircraft payload penalty.

NACA TN 4270

A PERFORMANCE ANALYSIS OF METHODS FOR HANDLING EXCESS INLET FLOW AT SUPERSONIC SPEEDS. Donald P. Hearth and James F. Connors. May 1958. 26p. diagrs., tab. (NACA TN 4270)

For the Mach 1.5 to 4.0 range, the following schemes were considered: normal- and oblique-shock spillage, bypass through an auxiliary exit, bypass to an ejector nozzle, and bypass through an auxiliary ram-jet engine. These methods were evaluated in terms of a thrust penalty for an assumed turbojet engine. Charts are presented for estimating these penalties for a range of mass flows and Mach numbers. Comparison of the various methods is also made on the basis of matching requirements for a hypothetical Mach 4.0 turbojet application.

CURRENT NACA RESEARCH REPORTS

NACA TN 4271

MAXIMUM THEORETICAL TANGENTIAL VELOCITY COMPONENT POSSIBLE FROM STRAIGHT-BACK CONVERGING AND CONVERGING-DIVERGING STATORS AT SUPERCRITICAL PRESSURE RATIOS. Thomas P. Moffitt. April 1958. 21p. diagrs. (NACA TN 4271)

The results of the investigation showed that converging stators are limited to exit tangential components of critical velocity ratios less than 1.714, while values up to the theoretical limit of 2.449 (corresponding to a Mach number of infinity) might be realized from converging-diverging stators. Unless design requirements are rigorous or unless extremely small blade exit angles as measured from the tangential are to be used, an approximate method of assuming uniform flow at the stator exit appears adequate in determining the maximum tangential velocity component possible from stators.

NACA TN 4274

MEASUREMENT OF THE EFFECT OF AN AXIAL MAGNETIC FIELD ON THE REYNOLDS NUMBER OF TRANSITION IN MERCURY FLOWING THROUGH A GLASS TUBE. Michel Bader and William C. A. Carlson. May 1958. 8p. diagrs. (NACA TN 4274)

Experiments were conducted to determine the effect of a 15,000 gauss axial magnetic field on the flow of mercury through a glass tube of 0.027-inch inside diameter. It was found that when only slight instabilities were present at Reynolds numbers from 5,000 to 8,000, the Reynolds number of transition could be increased by as much as 10 percent.

NACA TN 4276

AN APPROXIMATE ANALYTICAL METHOD FOR STUDYING ENTRY INTO PLANETARY ATMOSPHERES. Dean R. Chapman. May 1958. (i), 101p. diagrs., tab. (NACA TN 4276)

The complete pair of motion equations for entry into an exponential atmosphere is reduced to an ordinary, nonlinear differential equation of second order by introducing a certain mathematical transformation. This differential equation includes terms representing the gravity force, centrifugal force, lift force, drag force, and vertical acceleration. Solutions obtained for different types of entry are universal in the sense that a single solution determines the motion and heating of a vehicle of arbitrary weight, dimensions, and shape entering an arbitrary planetary atmosphere. Study is made of the decelerations, heating rates, and total heat absorbed for entry into Venus, Earth, Mars, and Jupiter.

ON THE MINIMUM DRAG OF THIN LIFTING BODIES IN STEADY SUPERSONIC FLOWS. G. N. Ward. October 1, 1956. 6p. ARC 18,711; FM 2459. (Ask for N-48079*)

The problem of calculating the minimum drag for a thin body with a given mean surface which is sustaining a given lift in a steady supersonic flow is reduced to a two-dimensional harmonic problem. The minimum drag is determined from the momentum integral for the smallest closed characteristic surface which just contains the body, but it is not certain that this minimum value can always be attained by a real body. It is shown that any larger characteristic surface leads to a smaller minimum drag which cannot be attained by a real body with the given mean surface.

MEASUREMENTS OF THE EFFECT OF SURFACE COOLING ON BOUNDARY LAYER TRANSITION ON A 15° CONE. PART 1. TESTS AT M = 2 AND 3 IN AN 8 IN. X 9 IN. WIND TUNNEL AT R. A. E./ BEDFORD. A. C. Browning, J. F. W. Crane, and R. J. Monaghan. 1958. 41p. diagrs., photos., tab. ARC CP 381. (Ask for N-58036X, pt.1*)

This was a steel cone, cooled internally by the circulation of cold alcohol. Results showed that when the ratio (surface temperature ahead of transition)/ (surface temperature for zero heat transfer) was reduced from 1.0 to 0.88, the transition RN at zero incidence was increased by a factor of about 1.8 for a local Mach number of 1.86 and by a factor of 1.24 to 1.43 for M = 2.81. The spread in the latter factor arose from alternative estimates of transition RN under zero heat transfer conditions, since at M = 2.81 this RN was dependent on stagnation pressure. Simultaneous records of transition position on the top and bottom generators of the cone were obtained in all cases, using the shadowgraph technique. Tests were also made at an incidence of 2°.

MECHANICAL PROPERTIES AT TEMPERATURES UP TO 300° C OF ALUMINIUM ALLOYS D.T.D. 546 AND H.S. 10 AT HIGH RATES OF HEATING AND STRAINING. M. S. Binning and B. Angell. November 1957. 22p. diagrs., photo., tabs. RAE Tech.Note Met.278. (Ask for N-60232*)

Tensile tests at room temperature, 100°, 200°, and 300° C have been made on specimens cut from aluminum alloy sheets to D.T.D. 546 and H.S. 10, the former being clad and the latter unclad. Specimens were raised to test temperature by resistance heating in 30 seconds and then tested at straining rates such that the 0.2-percent proof stress was reached in approximately 10 seconds. The decrease in proof stress with temperature was found to be similar for both materials; at 300° C the 0.2-percent proof stresses had decreased to 32 percent of their room temperature values. Seam welded specimens of D.T.D. 546 were tested and the weld efficiencies found to be 69 percent, 83 percent, and 98 percent at room temperature, 200°, and 300° C, respectively. Welded specimens were heated in an electric furnace and took 10 minutes to reach test temperature.

THE DEVELOPMENT OF HOT FLUIDISED BEDS FOR A LABORATORY THERMAL SHOCK TEST.
S. W. K. Shaw. February 1958. 33p. diagrs., photos., tabs. NGTE Memo. M.302.
(Ask for N-60233*)

A laboratory thermal shock test was required for studying the behavior and assessing the performance of useful and potentially useful materials for gas turbine blading. A method of rapidly cooling test specimens at a constant heat transfer coefficient had been developed using a fluidized bed as the cooling medium. This memorandum is concerned with the development of hot fluidized beds for rapidly heating the specimens. Five methods of heating fluidized beds were investigated, the most successful involving a spiral electric resistance heating element immersed in the bed. The critical mass flow to fluidize a granular material was found to decrease markedly and the maximum heat transfer coefficient to increase with temperature. Thermal shock tests on different shapes of test piece in brittle and ductile materials have shown this technique to be a reliable and reproducible means of studying thermal shock behavior.

Aeronautical Research Council (Gt. Brit.)
THE GROUND EFFECT ON THE JET FLAP IN TWO DIMENSIONS. D. J. Huggett. December 5, 1957. 19p. diagrs., photos. ARC 19,713; FM 2621; S & C 3232; Perf.1609. (Ask for N-60236*)

This paper presents the results of the first part of an experimental investigation of the ground effect on simple jet flap airfoils. In this part of the work an airfoil having a 58.1° jet flap was tested under two-dimensional conditions. The pressure lift on the airfoil was measured, with the ground at fixed positions, for varying jet momentum coefficients. It was found that the effect of the ground on the pressure lift was very small up to a certain critical jet coefficient. On increasing the jet coefficient beyond the critical value a marked loss of pressure lift was observed. This critical value referred to is approximately the same as the jet coefficient at which the jet first hits the ground.

Royal Aircraft Establishment (Gt. Brit.)
THE EFFECT OF WEATHERING ON THE MECHANICAL PROPERTIES OF "DURESTOS." D. J. McCue. December 1957. 12p. diagrs., photos., tabs. RAE Tech.Note Chem.1324. (Ask for CN-60373*)

Tests on the influence of weather over a 2-year period on the mechanical properties of both vacuum and "no-pressure" molded Durestos have been made. The protection offered by coating "Durestos" with "R.A.E. furane" and "synthetic silver" finishes has also been investigated. The wet and dry tensile strengths, dry compressive strength and tensile Young's modulus are tabulated. There is a brief account of weight changes during exposure. The general effect of weather over 2 years is a 4-percent decrease in load-carrying capacity, but as the standard deviation of the properties is of this order it would be necessary to organize a more detailed program to obtain statistically significant results, even if a 2-percent deterioration per year were maintained. The coatings used here are of little value as protection.

N-60518*

Aeronautical Research Council (Gt. Brit.)
CALCULATION OF DERIVATIVES FOR A CROPPED DELTA WING WITH AN OSCILLATING CONSTANT-CHORD FLAP IN A SUPERSONIC AIR STREAM. J. Watson, National Physical Laboratory. 1958. 34p. diagrs., tabs. ARC R & M 3059; ARC 18,001. (Ask for N-60518*)

The lift, pitching moment, and hinge moment are derived for a delta wing with a trailing-edge flap of constant chord when the wing is at zero incidence in a supersonic airstream and the flap oscillates harmonically with small amplitude and low frequency. It is assumed that the wing is sufficiently thin and the amplitude of oscillation sufficiently small to permit the use of linearized theory. Expressions for the various control derivative coefficients are obtained for a particular delta wing of aspect ratio 1.8 and taper ratio 1/7. The investigation covers partial-span flaps. The derivatives are evaluated and tabulated for Mach numbers 1.1, 1.2, 1.4, 1.6, and 2.0. The theory is shown to apply without appreciable error, provided that the frequency parameter based on mean chord does not exceed 0.4.

AN INVESTIGATION AT LOW SPEED OF THE FLOW NEAR THE APEX OF THIN DELTA WINGS WITH SHARP LEADING EDGES. B. J. Elle. January 9, 1958. 32p. diagrs., photos. ARC 19,780; Perf. 1621; FM 2629. (Ask for N-60739*)

The results of some water- and wind-tunnel tests on sharp-edged delta wings of low aspect ratio are presented. The position of the center line of the spiral leading-edge vortex is determined as a function of incidence and apex angle and a comparison is made with the theoretical results of Brown and Michael. The effects of Reynolds number, leading-edge shape and secondary separation are discussed and the breakdown of the flow pattern at high incidence is described.

THE VIBRATION OF CASCADE BLADES TREATED BY ACTUATOR DISC METHODS. D. S. Whitehead. July 26, 1957. 23p. diagrs. ARC 19,436; EA 594. (Ask for N-60740*)

This paper gives a theoretical method of calculating the aerodynamic forces on vibrating compressor and turbine blades subject to two fundamental limitations. These are firstly, that the time for the fluid to flow through the cascade must be small compared with the period of the vibration, and secondly, that adjacent blades must vibrate nearly in phase. This enables any kind of two-dimensional steady flow cascade data to be used. The methods given also allow the vibration forced by fluctuations in the incident flow to be calculated.

VECTORIAL ANALYSIS OF FLIGHT FLUTTER TEST RESULTS. E. G. Broadbent and E. Violet Hartley. February 1958. 44p. diagrs. RAE Tech. Note Structures 233. (Ask for N-60742*)

A binary flexure-torsion analysis has been made to check theoretically a method for the prediction of flutter which depends on plotting vectorially the amplitudes of response relative to the exciting force and extracting the relevant damping rate. The results of this calculation are given in the form of graphs both of the vector plots themselves and of the estimated damping rate against forward speed. The estimated damping rates are compared with calculated values. The method has the advantage that in a flight flutter test damping can be estimated from continuous excitation records; the method is an extension of the Kennedy and Pancu technique used in ground resonance testing.

THE THEORETICAL EVALUATION OF THE DOWNWASH BEHIND JET-FLAPPED WINGS. A. J. Ross. January 1958. 44p. diagrs., tab. RAE Report Aero 2599. (Ask for N-60751*)

The downwash behind jet-flapped wings of infinite and finite span has been evaluated, using the solutions given by Spence and Maskell for the flow in two and three dimensions respectively. The wing incidence and jet deflection are assumed to be small, and the displacement of the jet is taken into account by displacing the downwash field so that the relative distance between the jet and tailplane is correct. It is also assumed that the spanwise loading on the infinite wing is elliptic, and that the trailing vorticity is generated at one particular chordwise position. The wake is considered to be a flat sheet, and so the effect of the rolling up of the wake has been neglected. Charts are given for the functions required in the calculation of the downwash for four specific values of jet momentum coefficient.

SOME OBSERVATIONS ON THE FATIGUE BEHAVIOUR OF ALUMINIUM 7 PER CENT MAGNESIUM IN VARIOUS CONDITIONS OF HEAT TREATMENT. C. A. Stubbington. November 1957. 23p. diagrs., photos., tab. RAE Tech. Note Met. 279. (Ask for N-60753*)

Observations have been made on the qualitative and quantitative fatigue behavior of aluminum 7 percent magnesium in various conditions of heat treatment. The grain size of the material was varied by heat treatment and the effect of time at aging temperature for fine and coarse grain sizes examined. It was found that material in the extruded condition, having a small grain size, produced a steel type S-N curve but that the shape of this curve was altered to that typical of other aluminum alloys by any form of heat treatment, whether aging or solution treatment. Grain sizes appeared to be important in determining the fatigue properties of aluminum 7 percent magnesium, material in the extruded condition with fine grain size having higher fatigue endurances at 10^7 cycles and better fatigue ratios than solution treated material, in which grain growth had occurred, in all aged conditions. Cold working was found to improve the fatigue properties of solution treated aluminum 7 percent magnesium although the fatigue ratio of cold worked material was lower than that for extruded material with fine grain size. It was found that partial intercrystalline fatigue fracture could be observed in conditions of heat treatment in which, if the stress was unidirectional, the failure would be entirely transcrystalline and ductile.

Advisory Group for Aeronautical Research and Development. FLIGHT LOADS MEASUREMENTS ON NACA RESEARCH AIRPLANES. De E. Beeler, NACA. (Presented at Fifth meeting of AGARD Structures and Materials Panel, April 29-May 3, 1957, Copenhagen, Denmark.) April-May 1957. vii, 35p. diagrs., photos. AGARD Report 109. (Ask for N-51987X)

Flight loads investigations are conducted primarily for the purpose of confirming wind-tunnel results by comparing the full-scale results with comparable wind-tunnel results as frequently as deemed necessary; assessing the maneuvering conditions required of the aircraft and determining the associated dynamic loading conditions for the maneuvers; and bringing to light loads problems as a result of conducting flight research. The research airplane program in the United States included, from the beginning, extensive programs on flight loads measurements. This report summarizes some of the results from these investigations for three aircraft: the X-1 rocket-powered airplane, the X-5 variable-sweep airplane, and the XF-92A delta-wing airplane.

Advisory Group for Aeronautical Research and Development. FLIGHT TESTING FOR INERTIAL COUPLING CHARACTERISTICS. C. H. Meyer, Grumman Aircraft Engineering Corp. (Presented at 10th meeting of AGARD Flight Test Techniques Panel, May 20-24, 1957, London.) May 1957. 6p. AGARD Report 124. (Ask for CN-60279*)

The quest for high-speed and high-altitude performance has led to low-drag configurations in which a large proportion of the total mass of the aircraft is concentrated in the fuselage. The effect of this has been to increase the yawing and pitching moments of inertia and to reduce rolling moment of inertia, resulting in increased roll instability and finally in roll divergence. The causes and effects of roll divergence are discussed and possible approaches to the practical solution of the problem in the design of aircraft for specific roles are considered.

N-60455

Advisory Group for Aeronautical Research and Development. AIRCRAFT HANDLING QUALITIES AND PILOT RESPONSE CHARACTERISTICS. Charles B. Westbrook and Duane T. McRuer, WADC. (Presented at 10th meeting of AGARD Flight Test Techniques Panel, May 20-24, 1957, London.) May 1957. v, 21p. diagrs., tabs. AGARD Report 125. (Ask for N-60455)

The evolution of handling qualities requirements in the United States Air Force is traced. It is shown that pilot opinion upon which "classical" handling qualities are based is in reality a subjective expression of the overall suitability of a pilot-airframe system. The research program of the U. S. Air Force to determine the dynamic characteristics of the human pilot is reviewed. The ultimate purpose of this program is the application of human response data and servo analysis techniques to the design of overall systems incorporating such elements as the airframe, control system, pilot, displays, etc. Some of the recent results of correlation work to these two approaches to handling qualities are given.

Laboratories for Research and Development, Franklin Institute. WEAR OF SLIDING SEAL MATERIALS ON CHROMIUM-PLATED STEEL AT SPEEDS TO 60,000 FPM. William W. Shugarts, Jr. Prepared for NACA under NACA Contract NAw-6492. August 30, 1957. i, 29p. diagrs., tabs. Laboratories for Research and Development, Franklin Inst. Final Report F-A1985. (Ask for CN-60520*)

A study was made of the wear and friction characteristics of various materials at high speeds. Six graphite-base materials, two ceramics, and molybdenum were run against chromium-plated steel at essentially room temperature, 6.0 cm Hg air pressure, and unit contact pressures ranging from 100 to 400 psi. Tests of the phenol-resin impregnated graphite were made at various conditions of pressure and moisture content with air, oxygen, or nitrogen as the atmosphere. Little difference in the wear characteristics was found between the various impregnants used in graphite. The ceramics showed much higher wear than the graphites under comparable conditions. Increased oxygen and moisture in the test chamber caused accelerated wear.

FORCES AND MOMENTS ON POINTED AND BLUNT-NOSED BODIES OF REVOLUTION AT MACH NUMBERS FROM 2.75 TO 5.00. David H. Dennis and Bernard E. Cunningham. August 1952. 47p. diagrs., photo., tabs. (NACA RM A52E22)

Results of tests to determine the aerodynamic forces and moments on bodies of revolution at angles of attack from 0° to 25° are presented and compared with theory. Cones and ogives of fineness ratios 3 to 7 and two blunt-nosed body shapes with fineness ratios 3 and 5 were tested at Mach numbers from 2.75 to 5.00. Reynolds numbers were from 0.5 million to 6.4 million, depending on Mach number and body fineness ratio.

INVESTIGATION OF A FLOW DEFLECTOR AND AN AUXILIARY SCOOP FOR IMPROVING OFF-DESIGN PERFORMANCE OF NOSE INLETS. Warren E. Anderson and Richard Scherrer. July 1954. 32p. diagrs., photos. (NACA RM A54E06)

Flow deflectors and auxiliary scoops for improving off-design performance of nose inlets were investigated at low angles of attack and at Mach numbers from 0 to 1.50. Net performance based on effective-thrust ratios showed that both the deflector and auxiliary scoop can be advantageous for some flight applications.

NACA RM A56E23

EFFECT OF CAMBER ON THE DRAG OF A BODY OF REVOLUTION. Robert R. Dickey. October 1956. 8p. diagrs., tabs. (NACA RM A56E23)

The effect of camber on the drag of a body of revolution was investigated by measuring the drag, at transonic speeds, of two bodies that differed only in the amount of camber. It was found that the addition of a small amount of camber had a negligible effect on the minimum foredrag of the model tested.

NACA RM E7L02

INVESTIGATION OF EFFECTS OF SEVERAL FUEL-INJECTION LOCATIONS ON OPERATIONAL PERFORMANCE OF A 20-INCH RAM JET. W. H. Sterbentz, E. Perchonok, and F. A. Wilcox. June 8, 1948. 39p. diagrs., photos. (NACA RM E7L02)

Presents the results of an investigation conducted in the NACA Cleveland altitude wind tunnel to determine the effects of several fuel-injection locations on the operational performance of a 20-inch ram jet. The combustion effects of the several fuel-injection locations are analyzed in terms of ram-jet combustion-chamber-inlet variable of fuel-air ratio, velocity, and pressure. Combustion efficiency varies with combustion-chamber-inlet velocity and fuel-air ratio for various fuel-injection locations investigated. Combustion-chamber-inlet static pressure over the range investigated had little effect on combustion efficiency.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E50F16

ALTITUDE-TEST-CHAMBER INVESTIGATION OF PERFORMANCE OF A 28-INCH RAM-JET ENGINE. I - COMBUSTION AND OPERATIONAL PERFORMANCE OF FOUR COMBUSTION-CHAMBER CONFIGURATIONS. W. L. Jones, T. B. Shillito, and J. G. Henzel, Jr. August 23, 1950. 53p. diagrs., photos. (NACA RM E50F16)

An altitude-test-chamber investigation of a 28-inch-diameter ram-jet engine at a simulated flight Mach number of approximately 2.0 for altitudes of 40,000 to 50,000 feet was conducted at the NACA Lewis laboratory. Three different flame holders, varying in the number and size of the annular gutters, in conjunction with several fuel-injection systems were investigated. The combustion efficiency for the flame-holder fuel-injection system that provided the best overall operational fuel-air-ratio range (0.03 to 0.075) was over 0.9 at a fuel-air ratio of about 0.065 for the altitude range investigated.

NACA RM E50H21

ALTITUDE-TEST-CHAMBER INVESTIGATION OF PERFORMANCE OF A 28-INCH RAM-JET ENGINE. II - EFFECTS OF GUTTER WIDTH AND BLOCKED AREA ON OPERATING RANGE AND COMBUSTION EFFICIENCY. T. B. Shillito, W. L. Jones, and R. W. Kahn. November 6, 1950. 58p. diagrs. (NACA RM E50H21)

Altitude-test-chamber investigation of effects of flame-holder blocked area and gutter width on performance of 28-inch-diameter ram jet at simulated flight Mach number of 2.0 for altitudes from 40,000 to 55,000 feet was conducted at NACA Lewis laboratory. Ten flame holders investigated covered gutter widths from 1.00 to 2.50 inches and blocked areas from 40.5 to 62.0 percent of combustion-chamber area. Gutter width did not appreciably affect combustion efficiency. Increase in blocked area from 40 to 62 percent resulted in 5 to 10 percent increase in combustion efficiency. Increasing gutter width resulted in improvement in fuel-air-ratio operating range.

NACA RM E50J20

ALTITUDE-TEST-CHAMBER INVESTIGATION OF PERFORMANCE OF A 28-INCH RAM-JET ENGINE. III - COMBUSTION AND OPERATIONAL PERFORMANCE OF THREE FLAME HOLDERS WITH A CENTER PILOT BURNER. Thomas B. Shillito, George G. Younger, and James G. Henzel, Jr. February 6, 1951. 30p. diagrs. (NACA RM E50J20)

An altitude-test-chamber investigation of combustion performance of 28-inch-diameter ram-jet engine with a can-type center pilot burner was conducted for simulated flight Mach number of 2.0 at altitudes from 45,000 to 55,000 feet. Three different flame holders were used with a fixed fuel-injection system. The performance of the best pilot-burner configuration over the comparable range of fuel-air ratios was approximately the same as for the best configurations without a pilot burner, which were previously investigated, but the pilot burner had a lean limit of combustion at a fuel-air ratio of 0.02 compared with 0.03 for the configurations without a pilot burner.

#NACA RM SE51B02, by Lewis Laboratory Fuels Panel.

NACA RM E51D11

ALTITUDE-TEST-CHAMBER INVESTIGATION OF PERFORMANCE OF A 28-INCH RAM-JET ENGINE. IV - EFFECT OF INLET-AIR TEMPERATURE, COMBUSTION-CHAMBER-INLET MACH NUMBER, AND FUEL VOLATILITY ON COMBUSTION PERFORMANCE. Robert W. Kahn, Shigeo Nakanishi, and James L. Harp, Jr. July 1951. 27p. diagrs. (NACA RM E51D11)

Altitude-chamber investigation of 28-inch-diameter ram-jet engine was conducted to determine effects of inlet-air temperature, combustion-chamber-inlet Mach number and pressure, and fuel density and volatility on combustion performance. Results indicated that increasing inlet-air temperature extended operable range of fuel-air ratios, permitted operation at lower combustion-chamber pressures, and increased combustion efficiency; raising combustion-chamber-inlet Mach number increased minimum operational combustion-chamber-outlet pressure, lowered combustion efficiency, and reduced lean limit of combustion; and Diesel fuel decreased combustion efficiency 20 to 30 percent below that obtained with heptane for range of fuel-air ratios investigated.

NACA RM E52E14

PRELIMINARY INVESTIGATION OF EFFECT OF ANGLE OF ATTACK ON PRESSURE RECOVERY AND STABILITY CHARACTERISTICS FOR A VERTICAL-WEDGE-NOSE INLET AT MACH NUMBER OF 1.90. L. Abbott Leissler and Donald P. Hearth. August 1952. 11p. diagrs., photos. (NACA RM E52E14)

A preliminary investigation of an inlet consisting of a vertical wedge compression surface was conducted at a Mach number of 1.90 and at angles of attack from 0° to 10°. With a symmetrical cowling, pressure recovery and stability characteristics comparable to a conical inlet were observed; however, twin-duct flow interaction was observed. Modification of the inlet by cutting back the lower cowl lip and by perforating the wedge centerbody resulted in relatively constant maximum pressure recovery up to 10° angle of attack. These modifications also eliminated the twin-duct instability and increased the stable subcritical range of the inlet.

UNAVAILABLE; contains proprietary or obsolete information.

NACA RM E52L26

FREE-JET ALTITUDE INVESTIGATION OF A 20-INCH RAM-JET COMBUSTOR WITH A RICH INNER ZONE OF COMBUSTION FOR IMPROVED LOW-TEMPERATURE-RATIO OPERATION. Arthur M. Trout and Carl B. Wentworth. May 1953. 28p. diagrs., photo. (NACA RM E52L26)

An investigation of the altitude performance of a 20-inch-diameter high-temperature-ratio ram-jet combustor which had been redesigned to provide good combustor efficiency over a wide range of temperature ratios was conducted at zero angle of attack in a free-jet facility at a Mach number of 3.0. Configurations investigated incorporated a cylindrical control sleeve which confined the injected fuel at low overall fuel-air ratios to about 40 percent of the engine air flow. This provided an optimum fuel-air mixture over a portion of the flame holder when the overall fuel-air ratio was about 0.02. The configurations with the control sleeve operated with good combustor efficiency at fuel-air ratios as lean as 0.015, whereas the original engine had a lean blowout limit at a fuel-air ratio of about 0.03. The control sleeve had little effect upon the high-fuel-air-ratio performance of the engine.

NACA RM E53E08

INVESTIGATION OF LIQUID FLUORINE - LIQUID AMMONIA PROPELLANT COMBINATION IN A 100-POUND-THRUST ROCKET ENGINE. Edward A. Rothenberg and Howard W. Douglass. July 1953. 31p. diagrs., photos., tabs. (NACA RM E53E08)

The experimental performance of the liquid fluorine - liquid ammonia propellant combination was evaluated in 100-pound-thrust rocket engines operating at a chamber pressure of 300 pounds per square inch absolute. Several injector configurations were investigated. The maximum experimental specific impulse value was 270 pound-seconds per pound at 29 weight percent fuel and was obtained with a two-oxidant-on-one-fuel impinging-jet injector in a chamber of 50 inches characteristic length. The theoretical maximum, based on equilibrium composition expansion through the nozzle, is 311 pound-seconds per pound at 24 weight percent fuel.

NACA RM E53E20

A PRELIMINARY INVESTIGATION AT MACH NUMBER 1.91 OF AN INLET CONFIGURATION DESIGNED FOR INSENSITIVITY TO POSITIVE ANGLE-OF-ATTACK OPERATION. Milton A. Beheim. July 1953. 18p. diagrs., photos. (NACA RM E53E20)

A preliminary investigation of an inlet utilizing half of a conventional conical-centerbody supersonic diffuser with a flat plate as the upper surface was conducted at a Mach number of 1.91 and at angles of attack from -5° to 14°. High pressure recovery and critical mass-flow ratio were maintained at positive angles of attack. Various geometries of the flat plate were included in the investigation.

NACA RM E53E26

THE EFFECT OF INITIAL RATE OF SUBSONIC DIFFUSION ON THE STABLE SUBCRITICAL MASS-FLOW RANGE OF A CONICAL SHOCK DIFFUSER. J. C. Nettles. July 1953. 23p. diagrs. (NACA RM E53E26)

Experimental pressure recovery, mass-flow ratio, drag, and diffuser-discharge Mach number are presented for five nacelle-type conical spike inlets with the same supersonic compression and various subsonic-diffuser area variations. Stable mass-flow range is presented for free-stream Mach numbers of 1.5, 1.8, and 2.0. The effect of angle of attack on stable range is presented for zero to 9° at a Mach number of 2.0. Reducing the initial rate of subsonic diffusion was effective in improving the mass-flow range that could be achieved without pulsation. The diffuser with 3.5 hydraulic diameters of zero diffusion length at the entrance to the subsonic diffuser could be throttled for a range of 0.45 percent of maximum mass-flow ratio without oscillation.

NACA RM E54E05

ENGINE PERFORMANCE OF ALLOY 73J TURBINE BLADES CAST TO PREDETERMINED GRAIN SIZES. James R. Johnston, Charles A. Gyorgak, and John W. Weeton. July 1954. 27p. diagrs., photos., tab. (NACA RM E54E05)

The suitability of 73J alloy for turbine blade use and the effect of controlled grain size on engine performance of the alloy were investigated. The blades were cast to produce controlled grain sizes; classed fine, medium, and coarse. The blades were operated in a turbojet engine. Results of the engine test indicated that (1) engine life of 73J alloy blades is superior to S-816, (2) medium-grain blades have the longest life, coarse-grained, intermediate life, and fine-grained, shortest life, (3) grain sizes were uniform and consistent, and the grains in the fine-grained blades were unusually small for cast material.

NACA RM E54E10

DESIGN AND EXPERIMENTAL INVESTIGATION OF LIGHTWEIGHT BASES FOR AIR-COOLED TURBINE ROTOR BLADES. John C. Freche and Roy A. McKinnon. July 1954. 27p. diagrs., photos., tab. (NACA RM E54E10)

A design and experimental investigation was conducted on lightweight bases for air-cooled turbine rotor blades. Base designs which utilized forming and brazing techniques in their manufacture were developed, and samples of the designs were tested statically. Several samples were also endurance-tested in a turbojet engine. The most successful sample withstood engine operation at rated test-blade tip speed for 15 hours at coolant-flow ratios of 0.05 and 0.03. This base weighed 45 percent less than a comparable cast base.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E54E25

COOLING CHARACTERISTICS OF A TRANSPIRATION-COOLED AFTERBURNER WITH A POROUS WALL OF BRAZED AND ROLLED WIRE CLOTH. William K. Koffel. August 1954. 68p. diagrs., photos., tabs. (NACA RM E54E25)

Cooling data from this experimental afterburner are successfully correlated over a range of Reynolds number based on the distance downstream of the leading edge of the porous wall. Calculations based on the correlation indicate that the combustion-chamber cooling-air requirements for an exhaust-gas temperature of 3700° R are only 16 percent of the air required for conventional forced-convection cooling. The cooling-air requirements were nearly independent of flight condition, but close control of cooling-air pressure is required at high flight speeds.

NACA RM E54E27

PRELIMINARY WIND-TUNNEL INVESTIGATION OF TWO TYPES OF JET-EXIT CONFIGURATIONS FOR CONTROL OF AIRCRAFT. Gerald W. Englert and L. Abbott Leissler. August 1954. 20p. diagrs. (NACA RM E54E27)

A swiveled converging nozzle and a biconvex circular arc vane mounted in a shroud placed directly downstream of a convergent nozzle were studied, on a typical interceptor airplane, with the jet control surfaces deflected 0° and approximately 10°. The nozzle pressure ratio was varied from jet-off to 10. Normal forces obtained by swiveling the nozzle could be calculated quite closely from trigonometric relations. Some discrepancies were found between experimental and calculated values of the forces on the vanes. Changing the free-stream Mach number from 1.5 to 1.7 had no effect on internal performance.

NACA RM E55H29a

EFFECT OF HIGH ROTOR PRESSURE-SURFACE DIFFUSION ON PERFORMANCE OF A TRANSONIC TURBINE. James W. Miser, Warner L. Stewart, and Daniel E. Monroe. November 1955. 35p. diagrs., photos., tabs. (NACA RM E55H29a)

The subject turbine was investigated to determine the effect of high rotor pressure-surface diffusion on turbine performance. A comparison of the subject turbine with the most efficient transonic turbine in the present series of investigations showed that the efficiency of the subject turbine was almost as high, the suction-surface diffusion parameter was about the same, and the solidity was reduced by 36 percent. Because the loss per blade increased greatly with an increase in pressure-surface diffusion, the latter is also considered to be an important design consideration.

NACA RM E56E09a

AN ANALOG STUDY OF A SHOCK-POSITION DIFFUSER CONTROL ON A SUPERSONIC TURBOJET ENGINE. David Novik. August 1956. 27p. diagrs. (NACA RM E56E09a)

Shock position was assumed to be controlled by air bleed through a diffuser-exit bypass door operated by a second-order servomotor. Pressure disturbance resulting from changes in bypass-door position had a negligible effect on controlled engine speed, whereas a disturbance in engine speed had a large effect on diffuser pressure and could impose severe requirements on diffuser control response. The controlled diffuser response improved with faster servomotor response and smaller diffuser dead time and lag. The effect of diffuser dead time on diffuser response was greater than the effect of diffuser lag.

NACA RM E56E24

PERFORMANCE OF INCONEL 739 BUCKETS IN J33-9 TURBOJET ENGINE. C. A. Gyorgak and J. R. Johnston. October 1956. 19p. diagrs., photos., tabs. (NACA RM E56E24)

Investigation of the performance of Inconel 739 (a nickel-base alloy of low critical-element content) buckets in a J33-9 engine showed that Inconel 739 had an engine life at least equivalent if not superior to S-816 buckets operated at 1500° F. Inconel 739 buckets had a small scatter in life and exhibited lower total elongation than S-816. Bucket life was less than that predicted on the basis of stress-rupture considerations alone. The failure mechanism was probably influenced by fatigue.

NACA RM E56G31

ANALYTICAL INVESTIGATION OF SINGLE-STAGE-TURBINE EFFICIENCY CHARACTERISTICS IN TERMS OF WORK AND SPEED REQUIREMENTS. Warner L. Stewart. October 1956. 45p. diagrs. (NACA RM E56G31)

This report uses a work-speed parameter in describing single-stage full-admission turbine efficiency characteristics. The range of this parameter considered covers that used in turbojet engine applications as well as that being encountered in such applications as turbopump and accessory drives. Efficiency types considered are (a) total or aerodynamic efficiency, (b) rating efficiency, used in jet engine applications, and (c) static efficiency, used in turbopump and accessory drive applications. Velocity diagram types considered include zero exit whirl, impulse, and those corresponding to maximum values of efficiency.

NACA RM E56J19

ANALYSIS OF EFFICIENCY CHARACTERISTICS OF A SINGLE-STAGE TURBINE WITH DOWNSTREAM STATORS IN TERMS OF WORK AND SPEED REQUIREMENTS. William T. Wintucky and Warner L. Stewart. January 1957. 28p. diagrs. (NACA RM E56J19)

One-dimensional mean-section flow and blade specific losses proportional to average specific kinetic energy are assumed in the analysis. Range of the work-speed parameter λ considered includes low to moderate blade speeds with high specific work outputs, where critical turbojet, turbopump, and accessory-drive turbines are encountered. A diffusion factor of 0.5 limits the loading on the downstream stators. Turbine efficiencies considered are total or aerodynamic, rating, and static. Efficiencies of velocity-diagram types at impulse and that corresponding to values of maximum efficiency are presented and compared to indicate in what range of λ downstream stators are beneficial as well as the attending improvements in efficiency.

NACA RM E57B15

BONDED LEAD MONOXIDE FILMS AS SOLID LUBRICANTS FOR TEMPERATURES UP TO 1250° F. Harold E. Sliney and Robert L. Johnson. May 1957. 25p. diagrs., photos., tabs. (NACA RM E57B15)

Friction, wear, and endurance properties of PbO coatings, bonded to steel surfaces, were studied. The coatings were ceramic films containing PbO as the primary component. They functioned effectively on dry-film lubricants from 70° to 1250° F. The coatings prevented galling and excessive wear of the metal surfaces over the entire temperature range studied, but friction was much lower from 500° to 1250° F than at room temperature. Improved lubrication at the higher temperatures was apparently associated with the formation of glazed wear tracks on the coated surfaces. The methods of formulating and applying the coatings are described.

NACA RM E57F12

ANALYSIS OF TWO-STAGE-TURBINE EFFICIENCY CHARACTERISTICS IN TERMS OF WORK AND SPEED REQUIREMENTS. Warner L. Stewart and William T. Wintucky. August 1957. 45p. diagrs., tabs. (NACA RM E57F12)

A work-speed parameter, similar to that used previously for single-stage turbines, is used in analyzing the effect of mean-section velocity-diagram variations on two-stage-turbine efficiency characteristics. The range of this parameter is that considered of interest for turbojet, turbopump, and accessory-drive turbines. The principal assumption limits flow across any blade row to impulse conditions. The results of the analysis are compared with those obtained for the single-stage turbine to indicate the effects and advantages of multistaging.

NACA RM E57K22b

ANALYTICAL INVESTIGATION OF MULTISTAGE-TURBINE EFFICIENCY CHARACTERISTICS IN TERMS OF WORK AND SPEED REQUIREMENTS. Warner L. Stewart. February 1958. 18p. diagrs. (NACA RM E57K22b)

An analytical investigation of the interacting effects of turbine specific work output, rotor blade speed, stage number, and efficiency is presented. The correlating parameter used is a work-speed parameter, defined as the ratio of the mean-section blade speed squared to the specific work output. Major assumptions include equal stage work and blade speed, no reheat effect, and impulse conditions as the lower limit on rotor reaction. The results of the analysis include both stage and overall efficiency characteristics. Efficiency results presented include those based on turbine total-pressure and static- to total-pressure ratios.

NACA RM E57L05

ANALYSIS OF TWO-STAGE COUNTERROTATING TURBINE EFFICIENCIES IN TERMS OF WORK AND SPEED REQUIREMENTS. William T. Wintucky and Warner L. Stewart. March 1958. 33p. diagrs., tabs. (NACA RM E57L05)

A work-speed parameter previously reported is used to correlate efficiencies based on a one-dimensional mean-section, velocity-diagram analysis. Range covered includes turbojet, turbopump, and accessory-drive turbines. It is assumed that the blade specific losses are proportional to the average specific kinetic energy of the flow. Limits of the analysis are positive reaction and impulse across either or both rotors. Efficiencies are slightly higher than the conventional two-stage turbine because of the elimination of the interstage stator. Varying the rotor speed ratio has no effect on the general level of efficiencies but does change the impulse limits and the work split at which maximum efficiencies occur.

NACA RM H55E26

FLIGHT MEASUREMENTS OF THE LATERAL RESPONSE CHARACTERISTICS OF THE CONVAIR XF-92A DELTA-WING AIRPLANE. Euclid C. Holleman. August 1955. 37p. diagrs., tabs. (NACA RM H55E26)

Rudder pulse maneuvers were performed with the XF-92A 60° delta-wing airplane at 30,000 feet over a Mach number range of 0.52 to 0.92. Tests were conducted with and without a wing fence. Representative data were analyzed to give airplane stability derivatives and frequency responses.

NACA RM L50E17a

A PRELIMINARY FLIGHT INVESTIGATION OF THE EFFECT OF SNAKING OSCILLATIONS ON THE PILOTS' OPINIONS OF THE FLYING QUALITIES OF A FIGHTER AIRPLANE. *Arnold R. Beckhardt*, John A. Harper, and William L. Alford. September 26, 1950. 31p. diagrs., photos., tabs. (NACA RM L50E17a)

Results of tests in a typical low-wing, high-speed fighter showed that, in general, the pilots' perception of the snaking oscillation is mainly dependent on the transverse acceleration which the oscillation produces. In this airplane, an amplitude of ±0.02g was sometimes perceptible to the pilot, but an amplitude of ±0.025g was always perceptible and was considered unsatisfactory for a long flight while an amplitude of ±0.08g was considered very unsatisfactory. The effect of the snaking oscillation on the efficiency of the airplane as a gun platform and the results of a check on the present service requirements for lateral stability are also presented. A brief discussion of the design characteristics of the test apparatus used to vary the damping in yaw is also presented.

NACA RM L51E03

REVIEW OF THE MAXIMUM-LIFT CHARACTERISTICS OF THIN AND SWEPT WINGS. John G. Lowry and Jones F. Cahill. June 5, 1951. 10p. diagrs. (NACA RM L51E03)

A summary is presented of available data on maximum lift coefficients of thin and swept aircraft wings without fuselages or high-lift devices at Mach numbers up to 2.4. Data are presented to provide indications of the effects of plan form, Reynolds number, airfoil section, thickness, and rate of pitch.

NACA RM L51E14a

DIVISION OF LOAD AMONG THE WING, FUSELAGE, AND TAIL OF AIRCRAFT. *John P. Mayer and* Clarence L. Gillis. May 29, 1951. 14p. diagrs. (NACA RM L51E14a)

Results are presented for the division of load among the wing, fuselage, and tail for several aircraft configurations at subsonic and supersonic speeds.

NACA RM L51E17

FREE-FLIGHT-TUNNEL INVESTIGATION OF THE DYNAMIC LATERAL STABILITY AND CONTROL CHARACTERISTICS OF A HIGH-ASPECT-RATIO BOMBER MODEL WITH SELF-SUPPORTING FREE-FLOATING FUEL TANKS ATTACHED TO THE WING TIPS. Charles V. Bennett and Robert B. Cadman. August 1951. 12p. diagrs., tab. (NACA RM L51E17)

The results are presented of an experimental investigation conducted in the Langley free-flight tunnel to determine the dynamic lateral stability and control characteristics of a high-aspect-ratio bomber model with self-supporting, free-floating fuel tanks attached to the bomber wing tips.

NACA RM L51K14a

AERODYNAMIC CHARACTERISTICS AT SUPERSONIC SPEEDS OF A SERIES OF WING-BODY COMBINATIONS HAVING CAMBERED WINGS WITH AN ASPECT RATIO OF 3.5 AND A TAPER RATIO OF 0.2. EFFECT AT $M = 1.60$ OF NACELLE SHAPE AND POSITION ON THE AERODYNAMIC CHARACTERISTICS IN PITCH OF TWO WING-BODY COMBINATIONS WITH 47° SWEPTBACK WINGS. Lowell E. Hasel and John R. Sevier, Jr. January 1952. 31p. diagrs., photos., tabs. (NACA RM L51K14a)

An investigation has been conducted in the Langley 4- by 4-foot supersonic pressure tunnel to determine the effect of a series of nacelles on the aerodynamic characteristics in pitch of a sweptback-wing - body combination. Nacelle shape and position were varied on a configuration with a 6-percent-thick wing having an aspect ratio of 3.5, a taper ratio of 0.2, and 47° of sweep at the quarter chord. Submerged nacelles were tested on this wing-body combination and also on a similar configuration with a wing having a thickened root section. Lift, drag, and pitching-moment results are presented at a Mach number of 1.60 and a Reynolds number of 2.7×10^6 based on the wing mean aerodynamic chord.

NACA RM L51K15a

AERODYNAMIC CHARACTERISTICS AT SUPERSONIC SPEEDS OF A SERIES OF WING-BODY COMBINATIONS HAVING CAMBERED WINGS WITH AN ASPECT RATIO OF 3.5 AND A TAPER RATIO OF 0.2. EFFECTS OF SWEEP ANGLE AND THICKNESS RATIO ON THE STATIC LATERAL STABILITY CHARACTERISTICS AT $M = 1.60$. M. Leroy Spearman and John H. Hilton, Jr. January 1952. 31p. diagrs., tabs. (NACA RM L51K15a)

An investigation has been made to determine the lateral stability characteristics at $M = 1.60$ of 4-percent-thick wings having quarter-chord sweep angles of 10.8°, 35°, and 47° and of 47° sweptback wings having thickness ratios of 4, 6, and 9 percent. The effects of the installation of a nacelle on the 6-percent-thick 47° sweptback wing were also determined. Tests were made through an angle-of-yaw range from -2° to 10° at an angle of attack of 5° and through an angle-of-attack range from -2° to 13° at angles of yaw of 0° and 5°.

NACA RM L51K16a

AERODYNAMIC CHARACTERISTICS AT SUPERSONIC SPEEDS OF A SERIES OF WING-BODY COMBINATIONS HAVING CAMBERED WINGS WITH AN ASPECT RATIO OF 3.5 AND A TAPER RATIO OF 0.2. EFFECTS OF SWEEP ANGLE AND THICKNESS RATIO ON THE AERODYNAMIC CHARACTERISTICS IN PITCH AT M = 1.60. Ross B. Robinson and Cornelius Driver. January 1952. 27p. diagrs., photos., tabs. (NACA RM L51K16a)

An investigation has been made to determine the longitudinal characteristics at M = 1.60 of 4-percent-thick wings having quarter-chord sweep angles of 10.8°, 35°, and 47°, and of 47° sweptback wings having thickness ratios of 4, 6, and 9 percent. One thickened root, 6-percent-thick wing of 47° sweepback and a horizontal canard surface in combination with the 6-percent-thick 47° sweptback wing were also investigated. These tests were made through an angle-of-attack range of -2° to 13° at a Reynolds number of 2.7×10^6 based on the wing mean aerodynamic chord.

NACA RM L52E05b

A PROPOSED RAM-JET CONTROL SYSTEM OPERATED BY USE OF DIFFUSER PRESSURE RECOVERY. Maxime A. Faget. September 1952. 19p. diagrs. (NACA RM L52E05b)

A ram-jet fuel-control system which effects direct control of the thrust coefficient by maintaining a desired ratio between the measured total pressure and the diffuser exit pressure is described. A method for scheduling the thrust coefficient for any desired variation with Mach number is also described.

NACA RM L52E08

FREE-FLIGHT-TUNNEL INVESTIGATION OF THE DYNAMIC LATERAL STABILITY AND CONTROL CHARACTERISTICS OF A HIGH-ASPECT-RATIO BOMBER MODEL WITH A SWEPTBACK-WING FIGHTER MODEL ATTACHED TO EACH WING TIP. Charles V. Bennett and Peter C. Boisseau. September 1952. 17p. diagrs., tabs. (NACA RM L52E08)

The results are presented of an experimental investigation conducted in the Langley free-flight tunnel to determine the dynamic lateral stability and control characteristics of a high-aspect-ratio bomber model with a sweptback fighter model attached to each wing tip with freedom in roll. The outboard aileron of each fighter was operated automatically in response to the relative bank angle between the bomber and fighter to supply restoring moments to keep the fighter alined with the bomber wing. The effects of a variation in restoring moment and of the longitudinal position of the fighter models with respect to the bomber model were studied.

NACA RM L52E09

AERODYNAMIC CHARACTERISTICS AT SUPERSONIC SPEEDS OF A SERIES OF WING-BODY COMBINATIONS HAVING CAMBERED WINGS WITH AN ASPECT RATIO OF 3.5 AND A TAPER RATIO OF 0.2. EFFECTS OF SWEEP ANGLE AND THICKNESS RATIO ON THE AERODYNAMIC CHARACTERISTICS IN PITCH AT M = 2.01. Ross B. Robinson. July 1952. 27p. diagrs., photo., tabs. (NACA RM L52E09)

An investigation has been made to determine the aerodynamic characteristics in pitch at M = 2.01 of wings having quarter-chord sweep angles of 10.8°, 35°, and 47° for a thickness ratio of 4 percent and thickness ratios of 4, 6, and 9 percent for a quarter-chord sweep angle of 47°. One thickened root, 6-percent-thick wing at 47° sweepback and a horizontal canard surface in combination with the 6-percent-thick 47° sweptback wing were also investigated. These tests were made through an angle-of-attack range of -2° to 13° at a Reynolds number of 2.2×10^6 based on the wing mean aerodynamic chord.

NACA RM L52E23

AERODYNAMIC CHARACTERISTICS AT SUPERSONIC SPEEDS OF A SERIES OF WING-BODY COMBINATIONS HAVING CAMBERED WINGS WITH AN ASPECT RATIO OF 3.5 AND A TAPER RATIO OF 0.2. EFFECTS OF SWEEP ANGLE AND THICKNESS RATIO ON THE STATIC LATERAL STABILITY CHARACTERISTICS AT M = 2.01. Clyde V. Hamilton. August 1952. 37p. diagrs., tabs. (NACA RM L52E23)

An investigation has been made to determine the static lateral stability characteristics at M = 2.01 of 4-percent-thick wings having quarter-chord sweep angles of 10.8°, 35°, and 47° and of 47° sweptback wings having thickness ratios of 4, 6, and 9 percent and one additional 6-percent-thick wing with a thickened root section. The effects of the installation of nacelles on the 6-percent-thick 47° sweptback wing were also determined. Tests were made through an angle-of-yaw range from -4° to 8° at angles of attack of 0° and 5.3° and through an angle-of-attack range from -2° to 13° at angles of yaw of 0° and 5°.

NACA RM L52F03

AERODYNAMIC CHARACTERISTICS AT SUPERSONIC SPEEDS OF A SERIES OF WING-BODY COMBINATIONS HAVING CAMBERED WINGS WITH AN ASPECT RATIO OF 3.5 AND A TAPER RATIO OF 0.2. EFFECT AT M = 2.01 OF NACELLE SHAPE AND POSITION ON THE AERODYNAMIC CHARACTERISTICS IN PITCH OF TWO WING-BODY COMBINATIONS WITH 47° SWEPTBACK WINGS. Cornelius Driver. July 1952. 27p. diagrs., photos., tab. (NACA RM L52F03)

An investigation has been made to determine the effect of varying the nacelle shape and position on the longitudinal stability characteristics of a wing-body combination with a 6-percent-thick wing having an aspect ratio of 3.5, a taper ratio of 0.2, and 47° of

DECLASSIFIED NACA RESEARCH REPORTS

sweep at the quarter chord. Submerged nacelles were tested on this wing-body combination and on a similar configuration with a wing having a thickened root section. These tests were conducted at a Mach number of 2.01 and a Reynolds number of 2.2×10^6 based on the wing mean aerodynamic chord.

NACA RM L53E01

A STUDY OF VISUAL INTERCEPTION ATTACKS ON A NONMANEUVERING AIRPLANE TARGET. Donald C. Cheatham, Charles W. Mathews, and John A. Harper. July 1953. 97p. diagrs., photos., tabs. (NACA RM L53E01)

A study and evaluation of interception runs made by an experienced pilot flying a Grumman F9F-3 airplane against a nonmaneuvering airplane target are presented. Included are the control procedures and tracking characteristics displayed by the interceptor pilot, the effect of interceptor turning limitations, data pertaining to interceptor control operation, and evaluations applied to automatic control apparatus.

NACA RM L53E07a

EFFECTS OF A SERIES OF INBOARD PLAN-FORM MODIFICATIONS ON THE LONGITUDINAL CHARACTERISTICS OF TWO 47° SWEPTBACK WINGS OF ASPECT RATIO 3.5, TAPER RATIO 0.2, AND DIFFERENT THICKNESS DISTRIBUTIONS AT MACH NUMBERS OF 1.61 AND 2.01. Morton Cooper and John R. Sevier, Jr. July 1953. 43p. diagrs., photos., tabs. (NACA RM L53E07a)

Tests of a series of inboard plan-form modifications to two 47° sweptback wings of aspect ratio 3.5 and taper ratio 0.2 were conducted in the Langley 4- by 4-foot supersonic pressure tunnel at Mach numbers of 1.61 and 2.01. One wing had 6-percent-thick hexagonal airfoil sections of constant thickness ratio along the span; the other wing had the same sections outboard of the 40-percent-semispan station but with thickness linearly increasing to 12 percent at the model center line.

NACA RM L53E08b

A STUDY OF THE AERODYNAMIC LOADS ON SWEPTBACK WINGS AT TRANSONIC SPEEDS. Claude V. Williams and Richard E. Kuhn. June 1953. 14p. diagrs. (NACA RM L53E08b)

A study of the aerodynamic loads on sweptback wings at transonic speeds has been made and was concerned with an analysis of the effects of thickness-ratio, geometric-twist, and sideslip-angle variations. The study indicates that wing thickness ratio has an important effect on the variation of the spanwise center-of-pressure location with increasing Mach number.

NACA RM L54B17a

A WIND-TUNNEL INVESTIGATION OF THE FIRST-ORDER VIBRATORY STRESSES ON A FULL-SCALE SUPERSONIC-TYPE PROPELLER OPERATING IN AN ASYMMETRIC AIR FLOW. Atwood R. Heath, Jr., and Robert L. O'Neal. November 1954. 28p. diagrs., photo. (NACA RM L54B17a)

An investigation of the first-order, 1xP, vibratory-stress characteristics of a three-blade supersonic-type propeller of 12-foot diameter operating in an asymmetric air flow has been made on the NACA 6,000-horsepower propeller dynamometer in the Langley 16-foot transonic tunnel. The investigation covered a blade-angle range from 19.7° to 46.3°, a rotational-speed range from 1,300 to 2,100 rpm, and a forward Mach number range from 0.20 to 0.94. Comparisons of calculated and measured maximum 1xP stress locations and resonant frequencies are given, as well as the 1xP resonant stresses expected for the propeller installed on a hypothetical airplane.

NACA RM SL54D13a, by Queijo.

NACA RM L54E05

A WIND-TUNNEL INVESTIGATION OF THE USE OF SPOILERS FOR OBTAINING STATIC LONGITUDINAL STABILITY OF A CANARD-MISSILE MODEL IN REVERSE FLIGHT. Herman S. Fletcher. June 1954. 15p. diagrs., tab. (NACA RM L54E05)

Results are presented of a wind-tunnel investigation made to determine the effect of five spoilers of different heights on the stability in reverse flight of a canard-missile model that is stable in normal flight without spoilers. The spoilers had total heights that varied from 10 to 50 percent of the wing chord and were attached perpendicular to the forward edge of the leading surface so that they protruded equal distances above and below the surface of the wing along the entire span.

NACA RM L54E17

AN EXPERIMENTAL INVESTIGATION OF TWO-DIMENSIONAL, SUPERSONIC CASCADE-TYPE INLETS AT A MACH NUMBER OF 3.11. Edward Offenhartz. August 1954. 29p. diagrs., photos. (NACA RM L54E17)

A preliminary investigation of two-dimensional supersonic cascade-type inlets at a free-stream Mach number of 3.11 has been conducted at the Langley Aeronautical Laboratory. Two cascade-type inlets utilizing different methods of internal-flow compression were designed and tested. In one inlet (designated cascade inlet) the passages were contoured to generate coalesced compressions; whereas those of the other inlet (designated stepped-cascade inlet) were contoured to generate noncoalesced compressions. Pressure and Mach number distributions as well as shadowgraphs are presented for both inlets. With mass-flow ratios of 1, the maximum values of total-pressure recovery attained at 0° angle of attack were 0.43 and 0.45 for the cascade and stepped-cascade inlets, respectively.

NACA RM L54E25

AERODYNAMIC CHARACTERISTICS OF SEVERAL TIP CONTROLS ON A 60° DELTA WING AT A MACH NUMBER OF 1.61. Douglas R. Lord and K. R. Czarnecki. August 1954. 44p. diagrs., photos., tabs. (NACA RM L54E25)

An investigation has been made at a Mach number of 1.61 and a Reynolds number of 4.2×10^6 to determine the control effectiveness characteristics of seven tip controls on a 60° delta wing. Pressure-distribution measurements were made at angles of attack from 0° to 15° for control deflections from -30° to 30°. Integrated-pressure-distribution results are presented in the form of wing lift, bending-moment, and pitching-moment coefficients and control hinge-moment coefficients. The variations of control effectiveness with control deflection, wing angle of attack, hinge-line location, and control size and location are discussed as well as the effect of chordwise fences at the wing-control parting line and theoretical predictions.

NACA RM L54G22a

LOW-SPEED MEASUREMENT OF STATIC STABILITY AND DAMPING DERIVATIVES OF A 60° DELTA-WING MODEL FOR ANGLES OF ATTACK OF 0° TO 90°. Donald E. Hewes. September 1954. 30p. diagrs., photo., tab. (NACA RM L54G22a)

Measurements of the static stability, control characteristics, and damping derivatives of a 60° delta-wing model were made for a range of angles of attack of 0° to 90°. Tests were made with no vertical tails, and with 60° delta tails added on the top and bottom of the fuselage. Most of the tests were made at a Reynolds number of 830,000.

NACA RM L54G27

LOW-SPEED MEASUREMENTS OF ROLLING AND YAWING STABILITY DERIVATIVES OF A 60° DELTA-WING MODEL. Joseph L. Johnson, Jr. December 1954. 17p. diagrs., tab. (NACA RM L54G27)

Contains results of an investigation in the Langley free-flight tunnel to determine the low-speed rolling and yawing stability derivatives of a 60° delta-wing model from 0° to 30° angle of attack. The derivatives were measured by the free-to-damp oscillation technique and by the steady-roll technique.

NACA RM L55E11

EXPERIMENTAL FLUTTER RESULTS FOR CANTILEVER-WING MODELS AT MACH NUMBERS UP TO 3.0. W. J. Tuovila and John Locke McCarty. June 1955. 13p. diagrs., tab. (NACA RM L55E11)

Experimental flutter tests have been made at Mach numbers up to 3.0 using cantilever wing models with 0° to 60° sweepback and 45° and 60° delta-wing models. The effects of high Mach number and center-of-gravity location on the flutter trends are indicated. For wings with center-of-gravity location ahead of the midchord and with small sweep angles, the stiffness requirements to prevent flutter at a given altitude are determined essentially at transonic speeds. For wings with rearward center-of-gravity locations and high sweep angles, the stiffness requirements continue to increase with increase in Mach number. Shifting the center-of-gravity location forward reduces the stiffness requirements to prevent flutter, particularly for wings of low sweep angle.

NACA RM L55E16a

A DISCUSSION OF RECENT WIND-TUNNEL STUDIES RELATING TO THE PROBLEM OF ESTIMATING VERTICAL- AND HORIZONTAL-TAIL LOADS. Richard E. Kuhn, Joseph M. Hallissy, Jr., and Ralph W. Stone, Jr. July 1955. 20p. diagrs., photos. (NACA RM L55E16a)

Some of the effects of angle of attack, sideslip, Mach number, and airplane configuration on the loads on the vertical tail and, to a lesser extent, the loads on the horizontal tail are discussed. Also the division of load between the exposed vertical tail and the fuselage is considered. It is shown that at high angles of attack large rolled-up vortices from the wing and fuselage appear in the flow in the region of the tail assembly and cause large changes in both vertical- and horizontal-tail loads.

NACA RM L55E17

INVESTIGATION OF THE EFFECTS OF BODY INDENTATION AND OF WING-PLAN-FORM MODIFICATION ON THE LONGITUDINAL CHARACTERISTICS OF A 60° SWEPT-WING–BODY COMBINATION AT MACH NUMBERS OF 1.41, 1.61, AND 2.01. John R. Sevier, Jr. July 1955. 37p. diagrs., tab. (NACA RM L55E17)

An investigation has been made in the Langley 4- by 4-foot supersonic pressure tunnel to determine the effects of body indentation and of inboard wing-plan-form modification on the longitudinal characteristics of wing-body combinations. Tests were made at Mach numbers of 1.41, 1.61, and 2.01, and at a Reynolds number of 3.7×10^6 per foot. Results indicated that, by properly contouring the fuselage, an increase in maximum lift-drag ratio up to 20 percent could be realized at a Mach number of 1.41 (the design Mach number for one of the bodies); above this Mach

DECLASSIFIED NACA RESEARCH REPORTS

number, the improvement rapidly decreased. At the higher Mach numbers, 1.61 and 2.01, improvements in maximum lift-drag ratio up to 17 percent were obtained for the combinations by means of increasing the local wing chords over the inboard portion of the wing and thereby reducing the thickness ratio. At a Mach number of 1.41, this method was generally ineffective for increasing the maximum lift-drag ratio.

NACA RM L55E20

A THEORETICAL INVESTIGATION OF A COMPENSATING NETWORK WITH APPLICATION TO ROLL CONTROL SYSTEMS FOR AUTOMATIC INTERCEPTORS. Windsor L. Sherman. July 1955. 64p. diagrs., tab. (NACA RM L55E20)

A theoretical analysis of an airplane automatic control system incorporating a compensating network, a device which cancels airplane dynamics, is presented. The transfer function of this type of control system is derived and applied to the analysis of roll control systems. An analog-computer study was made to evaluate the effects of limiting the control-surface rate and displacement and of incomplete compensation on the response of the roll control systems. Results are presented as time histories of the airplane lateral and control-surface motions.

NACA RM L55E23

AN EXPERIMENTAL INVESTIGATION AT A MACH NUMBER OF 2.01 OF THE EFFECTS OF BODY CROSS-SECTION SHAPE ON THE AERODYNAMIC CHARACTERISTICS OF BODIES AND WING-BODY COMBINATIONS. Harry W. Carlson and John P. Gapcynski. July 1955. 29p. diagrs., tabs. (NACA RM L55E23)

An experimental investigation has been performed to determine the effect of changes in body cross-section shape on the aerodynamic characteristics of bodies and wing-body combinations. A series of 13 bodies having a given length and given longitudinal distribution of cross-sectional area but various cross-section shapes were tested at a Mach number of 2.01. The bodies were tested alone and in combination with a 47° sweptback wing having a 6-percent-thick hexagonal section.

NACA RM L55E23a

SUMMARY AND ANALYSIS OF HORIZONTAL-TAIL CONTRIBUTION TO LONGITUDINAL STABILITY OF SWEPT-WING AIRPLANES AT LOW SPEEDS. Robert H. Neely and Roland F. Griner. August 1955. ii, 133p. diagrs., tabs. (NACA RM L55E23a)

Available wind-tunnel data on the low-speed horizontal tail contributions to the static longitudinal stability of high-speed airplane configurations incorporating unswept and sweptback wings are summarized and analyzed. Air-flow characteristics behind wings and wing-body combinations are described and are related to the downwash at specific tail locations for unseparated and separated flow conditions. The effects of various tail-position parameters, wing parameters, stall-control devices, trailing-edge flaps, and ground interference on the air-flow characteristics and tail contribution are analyzed and demonstrated. An attempt has been made to summarize certain data by empirical correlation or theoretical means in a form useful for design. The experimental data herein were obtained mostly at Reynolds numbers greater than 4×10^6 and at Mach numbers less than 0.25.

NACA RM L55E27a

SIMULATOR STUDIES OF THE ATTACK PHASE OF AN AUTOMATICALLY CONTROLLED INTERCEPTOR. I - PRELIMINARY STUDIES OF THE LATERAL AND LONGITUDINAL CONTROL SYSTEMS. Albert A. Schy, Ordway B. Gates, Jr., and C. H. Woodling. II - SOME RESULTS OF A STUDY PERFORMED ON THE TYPHOON COMPUTER. Windsor L. Sherman and Leonard Sternfield. August 1955. 24p. diagrs. (NACA RM L55E27a)

The attack phase of the automatically controlled interceptor is studied in two parts. Part I is a limited simulation conducted to specify the lateral and longitudinal control systems for an automatic interceptor. The results are presented as Nyquist plots and time histories of the airplane variables. Part II uses the control systems developed in Part I, together with a dynamically perfect guidance system, to study the effect of the nonlinear terms in the complete equations of motion and nonlinear aerodynamics on the airplane response. The results are presented as time histories of the airplane and control surface motions.

NACA RM L56A26

A TRANSONIC WIND-TUNNEL INVESTIGATION OF STORE AND HORIZONTAL-TAIL LOADS AND SOME EFFECTS OF FUSELAGE-AFTERBODY MODIFICATIONS ON A SWEPT-WING FIGHTER AIRPLANE. Joseph M. Hallissy, Jr., and Louis Kudlacik. April 1956. 79p. diagrs., photos. (NACA RM L56A26)

An investigation has been conducted to determine: (a) pressure loads on a large store-pylon installation and the effect of the store on drag and stability, (b) span loading and hinge moments on a swept horizontal tail at 0° and 5° sideslip, and (c) transonic drag-rise reduction by afterbody enlargement. The model investigated had a wing of 40° sweep, aspect ratio 3.43, taper ratio 0.578, and NACA 64A010 airfoil sections perpendicular to the quarter-chord line. Tests were made at a Reynolds number of 5×10^6, at Mach numbers from 0.8 to 1.03, and at angles of attack to 17°.

NACA RM L56E01

A SEMIEMPIRICAL PROCEDURE FOR ESTIMATING WING BUFFET LOADS IN THE TRANSONIC REGION. T. H. Skopinski and Wilber B. Huston. September 1956. 22p. diagrs., tab. (NACA RM L56E01)

Wing buffeting data obtained from a flight loads investigation of two jet-propelled swept-wing airplanes were analyzed together with some published wind-tunnel results on two unswept-wing models to study the effects of Mach number and reduced frequency on the wing buffet loads. As a result of this analysis, a semiempirical procedure for a rough estimation of wing buffet loads has been derived which was based on simplified assumptions for the response of a linear single degree of freedom system. The procedure appeared to correlate the data from wings of various thickness ratios, stiffness, and size in the Mach number range from about 0.65 to 1.0.

NACA RM L56E10

EFFECT OF BLADE-SECTION CAMBER ON AERODYNAMIC CHARACTERISTICS OF FULL-SCALE SUPERSONIC-TYPE PROPELLERS AT MACH NUMBERS TO 1.04. Julian D. Maynard, John M. Swihart, and Harry T. Norton, Jr. October 1956. 79p. diagrs., photos., tab. (NACA RM L56E10)

This paper contains the results of an investigation of the aerodynamic characteristics of two full-scale supersonic-type propellers in the Langley 16-foot transonic tunnel with a 6,000-horsepower propeller dynamometer. The tests covered a range of blade angles at forward Mach numbers up to 1.04, and a few tests were made at lower speeds for low and negative blade angles. A brief analysis of the results is presented to show the effects of blade-section camber on propeller performance and stall-flutter characteristics. Stall flutter was also encountered at low and negative blade angles where the propeller might be used as a brake.

NACA RM L56E14

INVESTIGATION OF UNSTEADY FLOW PAST FOUR NACA 6-PERCENT-THICK AIRFOIL SECTIONS. Charles L. Ladson and Walter F. Lindsey. July 1956. 17p. diagrs. (NACA RM L56E14)

An investigation of the intensity of root-mean-square pressure pulsations and root-mean-square normal-force-coefficient fluctuations has been conducted on two NACA high-lift airfoils and two NACA 6-series airfoils. Data were obtained at angles of attack from 0° to 8° and over a Mach number range from 0.6 to 1.0. The corresponding Reynolds number range was from 1.6×10^6 to 2.1×10^6.

NACA RM L56E16

BLOWING OVER THE FLAPS AND WING LEADING EDGE OF A THIN 49° SWEPT WING-BODY-TAIL CONFIGURATION IN COMBINATION WITH LEADING-EDGE DEVICES. H. Clyde McLemore and Marvin P. Fink. July 1956. 57p. diagrs., photo. (NACA RM L56E16)

An investigation was conducted in the Langley full-scale tunnel to determine the effects on the low-speed aerodynamic characteristics of boundary-layer control by blowing over half- and full-span trailing-edge flaps of a large-scale wing-body-tail model in conjunction with several leading-edge-flow control devices, including leading-edge blowing. The wing and horizontal tail have an aspect ratio of 3.5, taper ratio of 0.3, 49° of sweep at the leading edge, and NACA 65A006 airfoil sections parallel to the plane of symmetry. The momentum coefficient range investigated was 0 to 0.16 for the trailing-edge blowing and 0 to 0.025 for the leading-edge blowing. Most of the tests were conducted at a Reynolds number of 5.20×10^6 corresponding to a Mach number of 0.08.

NACA RM L56E17

EFFECT OF WING HEIGHT AND DIHEDRAL ON THE LATERAL STABILITY CHARACTERISTICS AT LOW LIFT OF A 45° SWEPT-WING AIRPLANE CONFIGURATION AS OBTAINED FROM TIME-VECTOR ANALYSES OF ROCKET-PROPELLED-MODEL FLIGHTS AT MACH NUMBERS FROM 0.7 TO 1.3. Clarence L. Gillis and Rowe Chapman, Jr. September 1956. 70p. diagrs., photos., tabs. (NACA RM L56E17)

Lateral-stability flight tests were made over the Mach number range from 0.7 to 1.3 of models of three airplane configurations having 45° sweptback wings and tail surfaces. One configuration had a high wing; one, a low wing; and one, a high wing with 10° cathedral. The lateral oscillations resulting from intermittent yawing disturbances were interpreted in terms of typical full-scale airplane flying qualities and were further analyzed by the time-vector method to obtain lateral stability derivatives. Information was obtained on C_{Y_β}, C_{n_β}, C_{l_β}, C_{l_p}, $C_{n_r} - C_{n_{\dot{\beta}}}$, and $C_{l_r} - C_{l_{\dot{\beta}}}$. Comparisons were made with other experimental and theoretical results.

NACA RM L56E18

THE VARIATION WITH WING ASPECT RATIO OF FLAP EFFECTIVENESS ON THIN RECTANGULAR WINGS AT TRANSONIC SPEEDS. John G. Lowry and Robert T. Taylor. August 1956. 60p. diagrs., tabs. (NACA RM L56E18)

This paper presents the results of an investigation at transonic speeds to determine the effects of flap-chord ratio, wing aspect ratio, and wing thickness on the control effectiveness of full-span plain sealed flaps on 31 small-scale rectangular unswept wings.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L56E28

A BRIEF SUMMARY OF EXPERIENCE IN BOOSTING AERODYNAMIC RESEARCH MODELS. Joseph G. Thibodaux, Jr. (Report is basis of talk presented at the thirtieth meeting of Bumblebee Aerodynamics Panel, Buffalo, New York, January 4, 1956.) July 1956. 21p. diagrs., photos. (NACA RM L56E28)

Single and multiple clusters of booster rockets in two-, three-, and four-stage combinations, and in tandem, wrap-around, underslung, and towing arrangements have been successfully used to propel various pilotless aircraft research model configurations. Results obtained with these unusual configurations along with some of the problems encountered and the factors responsible for choice of a particular configuration are briefly discussed.

NACA RM L56E30a

WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF WING THICKNESS ON THE STATIC LONGITUDINAL AND LATERAL STABILITY OF UNSWEPT WINGS OF ASPECT RATIO 3 AT HIGH SUBSONIC SPEEDS. William C. Hayes, Jr., and Edward C. Polhamus. August 1956. 43p. diagrs., photos. (NACA RM L56E30a)

An investigation was made to determine the effect of wing thickness on static longitudinal and lateral stability of a wing-fuselage combination at high subsonic speeds. The wings had an aspect ratio of 3, a taper ratio of 0.5, zero sweep of the half-chord line, and NACA 65A002, NACA 65A004, and NACA 65A006 airfoil sections parallel to the plane of symmetry. The variations of side force, yawing moment, and rolling moment with angle of sideslip were obtained as a continuous trace through the angle-of-sideslip range in order to detect any nonlinearities.

NACA RM L57F12

STATUS OF SPIN RESEARCH FOR RECENT AIRPLANE DESIGNS. Anshal I. Neihouse, Walter J. Klinar, and Stanley H. Scher. August 1957. ii, 98p. diagrs., photos., tabs. (NACA RM L57F12)

The status of spin research for recent airplane designs is presented in terms of the following major problem areas: interpretation of results of spin-model research, analytical spin studies, techniques involved in the measurement of various parameters in the spin, effectiveness of controls during spins and recoveries, influence of long noses, strakes, and canards on spin and recovery characteristics, and correlation of airplane and model spin and recovery characteristics.

NACA RM L57F26

COMPRESSIBILITY EFFECTS ON A HOVERING HELICOPTER ROTOR HAVING AN NACA 0018 ROOT AIRFOIL TAPERING TO AN NACA 0012 TIP AIRFOIL. Robert D. Powell, Jr. September 1957. 25p. diagrs. (NACA RM L57F26)

An investigation has been conducted on the Langley helicopter test tower to determine experimentally the effects of compressibility on the hovering performance and the blade pitching moments of a helicopter rotor having an NACA 0012 tip airfoil and an NACA 0018 root airfoil. Data are presented for blade-tip Mach numbers from 0.33 to 0.88. Experimental drag-divergence data are compared to unpublished two-dimensional data for the NACA 0012 airfoil section.

NACA RM L57G11a

THEORETICAL DETERMINATION OF LOW-DRAG SUPERCAVITATING HYDROFOILS AND THEIR TWO-DIMENSIONAL CHARACTERISTICS AT ZERO CAVITATION NUMBER. Virgil E. Johnson, Jr. September 1957. 29p. diagrs. (NACA RM L57G11a)

Two new low-drag hydrofoils for operation at zero cavitation number are derived by the application of the Tulin-Burkart linearized theory. The two-dimensional lift-drag ratios of these two hydrofoils operating at design angle of attack are shown to be, theoretically, about 45 and 80 percent greater than the Tulin-Burkart configuration. A simplified calculation of the location of the upper cavity streamline for arbitrary configurations is also presented.

NACA RM L57I16

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF ARBITRARY ASPECT RATIO, SUPERCAVITATING HYDROFOILS OPERATING NEAR THE FREE WATER SURFACE. Virgil E. Johnson, Jr. December 1957. 94p. diagrs., photos. (NACA RM L57I16)

The existing two-dimensional theory for the characteristics of supercavitating hydrofoils operating at zero cavitation number is modified to include the effects of camber, aspect ratio, and depth of submersion. For a comparison with the theory, two aspect-ratio-1 hydrofoils, a flat plate and one with a cambered lower surface, were tested by operating them near the water surface so that their upper surfaces were completely ventilated. The data obtained verified the theory to within 3 percent. Some experimental data are also presented for the models operating at nonzero cavitation number for both air and water-vapor-filled cavities.

This is authority for those possessing copies of the following research reports to declassify them from Secret. Effective date of declassification April 15, 1958.

NACA RM E52B28

CALCULATION OF INTERNAL PRESSURES IN THE FUEL TUBE OF A NUCLEAR REACTOR. B. M. Rosenbaum and G. Allen. July 1952. 32p. tabs. (NACA RM E52B28)

General procedures for computing internal pressures in fuel tubes of nuclear reactors are developed, and the effects on the pressure of varying neutron flux, fissioning material, operating time, and operating temperature are discussed. An account of chemical interactions between the many fission-product elements and the resulting effect on the total pressure completes the discussion. These general methods are illustrated by calculations applied to a system consisting of 90 percent enriched U^{235} in the form of UO_2 packed into a hollow metal cylinder or "pin," operating at a flux of 8×10^{14} per sec per cm^2 at 2000° F.

NACA RM E52L22

EFFECT OF DRAWBAR UPSTREAM LOCATION ON AIR VELOCITY DISTRIBUTION AT THE INLET FACE OF REACTOR SEGMENT DESIGNED BY THE GENERAL ELECTRIC COMPANY. T. F. Nagey and E. W. Sams. January 1953. 11p. diagrs. (NACA RM E52L22)

The results of flow tests on a drawbar for the General Electric reactor segment test in the MTR are reported. The drawbar is a T-shaped obstruction located as close to the upstream face of the reactor test segment as possible without serious flow distortion; the drawbar is required for instrumentation leads and segment insertion and removal in the MTR. The effect of drawbar upstream distance on velocity distribution across the segment face is evaluated for several Reynolds numbers.

NACA RM E53B05

EFFECT OF CAPTURE ON THE SLOWING-DOWN LENGTH OF NEUTRONS IN HYDROGENOUS MIXTURES CONTAINING URANIUM. H. C. Volkin and L. Soffer. April 1953. 4p. tab. (NACA RM E53B05)

Fermi's derivation for the slowing-down length of neutrons in hydrogenous media has been generalized to include capture while retaining the assumption of infinite mass for the nonhydrogen nuclei. Both the capture and the no-capture formulas have been applied to a mixture of uranium-235 and water with the ratio of hydrogen to uranium nuclei chosen as 25. Results show that capture reduced the calculated L_f^2 by 9.5 percent. A further calculation using the total mean free path in the no-capture formula gave an L_f^2 differing by 3.9 percent from that given by the capture formula.

NACA RM E53B26

COMPARISON OF CALCULATED AND MEASURED THERMAL DISTORTIONS IN A REACTOR CONTROL ROD FOR TEMPERATURE PATTERNS SIMULATING TWO REACTOR OPERATING CONDITIONS. Tibor F. Nagey. April 1953. 18p. diagrs., tabs. (NACA RM E53B26)

The results of a simplified theoretical analysis of the calculated distortion of a stainless-steel-clad silver-cadmium control rod under the influence of several temperature patterns are compared with the measured distortions for the same temperature patterns. The calculated distortion for a temperature variation simulating reactor operation with 50-percent shim-rod insertion agreed with the measured values for about the first 60 percent of rod length, measured from the fixed end. The calculated distortion for temperature variation simulating reactor operation with shim rod removed agreed with measured values over the entire length of rod.

NACA RM E53L18

FORCED-CONVECTION HEAT-TRANSFER CHARACTERISTICS OF MOLTEN FLINAK FLOWING IN AN INCONEL X SYSTEM. Milton D. Grele and Louis Gedeon. February 1954. 23p. diagrs., photos., tab. (NACA RM E53L18)

Heat-transfer characteristics of Flinak (NaF-KF-LiF, 11.4-42.0-46.5 mole percent) flowing through an electrically heated test section were investigated. Average heat-transfer coefficients were about 40 percent of the values given by the McAdams correlation line. Similar results were obtained by another investigator using an Inconel test section. The low values may be due to a scale formation and some intergranular penetration found on the inner surface of the tube.

NACA Rept. 1325

AVERAGE PROPERTIES OF COMPRESSIBLE LAMINAR BOUNDARY LAYER ON FLAT PLATE WITH UNSTEADY FLIGHT VELOCITY. Franklin K. Moore and Simon Ostrach. 1957. iii, 12p. diagrs., tabs. (NACA Rept. 1325. Supersedes TN 3886)

The time-average characteristics of boundary layers over either an insulated or isothermal flat plate in nearly quasi-steady flow are determined. Time averages are found without specifying plate velocity explicitly except that it is positive and has an average value. The time average quasi-steady terms are compared to steady flow values at the corresponding average velocity and the effects of the frequency dependent averages are discussed. The special case of harmonic velocity variation is considered, and it is found that large amplitudes accentuate the importance of the frequency-dependent terms. Oscillating the wall to increase the heat-transfer rate is not advantageous if the power to oscillate the plate is accounted for, unless the Prandtl number is in a certain range.

NACA Rept. 1338

NEAR NOISE FIELD OF A JET-ENGINE EXHAUST. Walton L. Howes, Edmund E. Callaghan, Willard D. Coles, and Harold R. Mull. Appendix B: CORRELATION COMPUTER. Channing C. Conger and Donald F. Berg. 1957. ii, 35p. diagrs., photos., tab. (NACA Rept. 1338. Supersedes TN 3763 and TN 3764)

Surveys of sound pressures and longitudinal and lateral cross correlations, both overall and in frequency bands, are presented for a fixed operating condition. The dependence on jet velocity and the effect on a stiff plate are shown. Sound-pressure data with afterburning are included. The distribution of acoustic sources according to frequency was found. The physical significance of cross correlation is outlined. The extent of positive correlation increased downstream, but was relatively independent of jet velocity and filter-band width. Sound pressures were increased on the plate, but correlation was unaffected.

NACA RM A58D17

DATA FROM FLOW-FIELD SURVEYS BEHIND A LARGE-SCALE THIN STRAIGHT WING OF ASPECT RATIO 3. William T. Evans. June 1958. 13p. diagrs. (NACA RM A58D17)

The wing section was a modified double wedge, 4.2 percent thick. Surveys were made in the Ames 40- by 80-foot wind tunnel at angles of attack from 8° to 30°. The dynamic pressure was 20 lb/sq ft and the Reynolds number 8.5×10^{6}. Limited force data with and without a horizontal tail are included. Longitudinal instability and loss of control effectiveness above the stall were traced to a region of high downwash and low dynamic pressure above and behind the wing.

NACA RM E58D11

COMPATIBILITY OF METALS WITH LIQUID FLUORINE AT HIGH PRESSURES AND FLOW VELOCITIES. Harold W. Schmidt. July 1958. 15p. diagrs., photo., tab. (NACA RM E58D11)

Nickel, stainless steel, brass, and aluminum were evaluated for compatibility with liquid fluorine at flow velocities up to approximately 400 ft/sec and pressures up to 1500 lb/sq in. gage. Configurations were varied to produce severe turbulence and impact effects. Two rotating-vane flowmeters were also tested. None of the metals exhibited any measurable physical or chemical changes. In a run made with Teflon, fluorine reacted violently.

NACA TM 1435

ELLIPTIC FUNCTIONS AND INTEGRALS WITH REAL MODULUS IN FLUID MECHANICS. (Les Fonctions et Intégrales Elliptiques a Module Réel en Mécanique des Fluides). Robert Legendre. June 1958. 113p. diagrs. (NACA TM 1435. Translation of Office National d'Études et de Recherches Aéronautiques, Publication 71, 1954)

The usefulness of the Schwarz transformation and elliptic functions in defining flows outside and inside polygons is discussed and illustrated. The mathematical properties and physical significance of the elliptic integrals of the first, second, and third kinds and of the elliptic functions are examined, together with their relations to the theta and zeta functions. Applications of the various functions are made to the calculation of wing profiles, of compressor profiles, and to the study of the vibration of airplane wings and of compressor vanes.

CURRENT NACA RESEARCH REPORTS

NACA TM 1436

STATISTICAL STUDY OF TURBULENCE - SPECTRAL FUNCTIONS AND CORRELATION COEFFICIENTS. (Étude statistique de la turbulence. Fonctions spectrales et coefficients de corrélation.) Francois N. Frenkiel. July 1958. 116p. diagrs., tabs. (NACA TM 1436. Translation of Office National d'Études et de Recherches Aéronautiques. Rapport Technique no. 34, 1948)

An extensive discussion is given of various possible correlation functions for homogeneous and isotropic turbulence. The logical consequence of each of several choices of such correlation functions is examined in detail.

NACA TN 3786

HANDBOOK OF STRUCTURAL STABILITY. PART VI - STRENGTH OF STIFFENED CURVED PLATES AND SHELLS. Herbert Becker, New York University. July 1958. iii, 82p. diagrs., tab. (NACA TN 3786)

A comprehensive review of failure of stiffened curved plates and shells is presented. Panel instability in stiffened curved plates and general instability of stiffened cylinders are discussed. The loadings considered for the plates are axial, shear, and the combination of the two. For the cylinders, bending, external pressure, torsion, transverse shear, and combinations of these loads are considered. When possible, test data and theory were correlated.

NACA TN 4080

SOME EFFECTS OF VANES AND OF TURBULENCE IN TWO-DIMENSIONAL WIDE-ANGLE SUBSONIC DIFFUSERS. Carl A. Moore, Jr., and Stephen J. Kline, Stanford University. June 1958. iii, 139p. diagrs., photos., tabs., film suppl. available on request. (NACA TN 4080)

Tests on two aspects of the behavior of wide-angle, plane-walled, two-dimensional diffusers with essentially incompressible flow have been conducted. A thorough study of the flow mechanism has been made using dye injection in a water table. The four regimes of flow found are delineated on graphs in terms of the three important parameters. Test data from large and small water-table units are given. Data are also presented which demonstrate means for producing efficient diffusers with total included angles up to 45° by use of simple, short, flat vanes.

NACA TN 4134

STALL PROPAGATION IN A CASCADE OF AIRFOILS. Anthony R. Kriebel, Barry S. Seidel, and Richard G. Schwind, Massachusetts Institute of Technology. June 1958. 122p. diagrs., photos., tabs. (NACA TN 4134)

An experimental investigation of stall propagation in a stationary circular cascade in which high-speed schlieren and interferometer photography is used is described. This investigation suggests an analytical approach to the study of stall propagation which is valid only for an isolated blade row in an infinite flow field but which is not restricted to small unsteady perturbations or to an assumed simplified cascade geometry. Conditions necessary for the existence of the assumed type of stall cells are described and equations are derived for the velocity of stall-cell propagation.

NACA TN 4186

HEAT TRANSFER IN ISOTROPIC TURBULENCE DURING THE FINAL PERIOD OF DECAY. D. W. Dunn and W. H. Reid, Johns Hopkins University and Ballistic Research Laboratories, U. S. Army. June 1958. 68p. diagrs., tabs. (NACA TN 4186)

The problem of heat transfer in isotropic turbulence with a constant mean temperature gradient is considered during the final period of decay. The Reynolds and Péclet numbers are then very small, and all triple correlation terms can be neglected in the equations for the double correlations. On this basis it is found that the temperature field ultimately becomes independent of the initial conditions on the temperature and has characteristics determined only by the mean temperature gradient, the physical properties of the fluid, and the characteristics of the turbulence. Detailed analytical and numerical results are obtained for the asymptotic state.

NACA TN 4187

HIGH-SPEED HYDRODYNAMIC CHARACTERISTICS OF A FLAT PLATE AND 20° DEAD-RISE SURFACE IN UNSYMMETRICAL PLANING CONDITIONS. Daniel Savitsky, R. E. Prowse, and D. H. Lueders, Stevens Institute of Technology. June 1958. 93p. diagrs., photos., tabs. (NACA TN 4187)

The results of an investigation made to obtain the wetted areas, the three components of planing forces, and the three components of moments acting on a 0° and a 20° dead-rise surface in high-speed, unsymmetrical planing conditions are presented. Hydrodynamic data were obtained for trim angles between 6° and 30°, roll angles between -15° and 15°, yaw angles between 0° and 20°, mean wetted-length—beam ratios up to 7.7, load coefficients up to 49.0, and speed coefficients up to 18.0.

CURRENT NACA RESEARCH REPORTS

NACA TN 4237

GENERAL INSTABILITY OF STIFFENED CYLINDERS. Herbert Becker, New York University. July 1958. 26p. diagrs., tab. (NACA TN 4237)

Theoretical buckling stresses are determined in explicit form for circular cylinders with circumferential and axial stiffening. The loadings are axial compression, radial pressure, hydrostatic pressure, and torsion. Analyses were confined to moderate-length and long cylinders. Derivation of a form of Donnell's equation applicable to orthotropic cylinders is presented in this report.

NACA TN 4238

NORMAL COMPONENT OF INDUCED VELOCITY FOR ENTIRE FIELD OF A UNIFORMLY LOADED LIFTING ROTOR WITH HIGHLY SWEPT WAKE AS DETERMINED BY ELECTROMAGNETIC ANALOG. Walter Castles, Jr., Howard L. Durham, Jr., and Jirair Kevorkian, Georgia Institute of Technology. June 1958. 33p. diagrs., photos., tabs. (NACA TN 4238)

Values of the normal component of induced velocity throughout the entire field of a uniformly loaded rotor at high speed are presented in the form of charts and tables. Many points were found by an electromagnetic analog, details of which are given. Comparisons of computed and analog values for the induced velocity indicate that the latter are sufficiently accurate for engineering purposes.

NACA TN 4243

AN EXPERIMENTAL STUDY OF THE TURBULENT BOUNDARY LAYER ON A SHOCK-TUBE WALL. Paul B. Gooderum. June 1958. 63p. diagrs., photos., tab. (NACA TN 4243)

Interferometric measurements were made of the density profiles of an unsteady turbulent boundary layer on the flat wall of a shock tube. The investigation included both subsonic and supersonic flow (Mach numbers of 0.50 and 1.77) with no pressure gradient and with heat transfer to a cold wall. Velocity profiles and average skin-friction coefficients were calculated. Effects on the velocity profile of surface roughness and flow length are examined.

NACA TN 4244

ON SOLUTIONS FOR THE TRANSIENT RESPONSE OF BEAMS. Robert W. Leonard. June 1958. 65p. diagrs., tabs. (NACA TN 4244)

Williams type modal solutions of the elementary and Timoshenko beam equations are presented for the response of several uniform beams to a general applied load. Example computations are shown for a free-free beam subject to various concentrated loads at its center. Discussion includes factors influencing the convergence of modal solutions and factors to be considered in a choice of beam theory. Results obtained by two numerical procedures, the traveling-wave method and Houbolt's method, are also presented and discussed.

NACA TN 4245

FLUTTER ANALYSIS OF RECTANGULAR WINGS OF VERY LOW ASPECT RATIO. Robert W. Fralich and John M. Hedgepeth. June 1958. 24p. diagrs. (NACA TN 4245)

This flutter analysis employs slender-body aerodynamic theory and thin-plate theory. The spanwise variation of wing deflection is assumed to be given by a parabola, and the chordwise variation is allowed complete freedom. The results show the variation of flutter speed and mode shape with aspect ratio. Comparisons are made with additional results obtained by approximating the chordwise deflection shape by use of parabolic or cubic curves. The analysis shows that the cubic approximation gives good results for a ratio of chord to semispan less than 3.

NACA TN 4246

FURTHER INVESTIGATION OF FATIGUE-CRACK PROPAGATION IN ALUMINUM-ALLOY BOX BEAMS. Herbert F. Hardrath and Herbert A. Leybold. June 1958. 23p. diagrs., tabs. (NACA TN 4246)

Results are presented for several designs of built-up box beams tested at one load level. Stress redistribution during the tests was studied to aid in interpreting the results. Parameters which varied were the material of construction, mode of connecting stringers to cover skins, ratio of stringer area to skin area, and location of rivets with respect to line of crack propagation.

NACA TN 4250

EFFECT OF THE PROXIMITY OF THE WING FIRST-BENDING FREQUENCY AND THE SHORT-PERIOD FREQUENCY ON THE AIRPLANE DYNAMIC-RESPONSE FACTOR. Carl R. Huss and James J. Donegan. June 1958. 45p. diagrs. (NACA TN 4250)

The results are presented in the form of preliminary design charts which give a comparison between the dynamic-response factors of the semirigid case and the airplane longitudinal short-period case and between the dynamic-response factors of the semirigid case and the steady-state value of the airplane longitudinal short-period response. These charts can be used to estimate the first-order effects of the addition of a wing-bending degree of freedom on the short-period dynamic-response factor and on the maximum dynamic-response factor when compared with the steady-state response of the system.

CURRENT NACA RESEARCH REPORTS

NACA TN 4252

EXPERIMENTAL INVESTIGATION OF AN IMPULSE-TYPE SUPERSONIC COMPRESSOR ROTOR HAVING A TURNING OF 73° AT THE MEAN RADIUS. James R. Sterrett. June 1958. 35p. diagrs., photos., tabs. (NACA TN 4252)

An impulse rotor with guide vanes was designed and tested in Freon-12. The rotor had an inlet and exit hub-tip ratio of 0.575 and 0.75, respectively. The blade-passage design was based on a two-dimensional vortex-flow theory modified to account partially for three-dimensional compressions. The rotor achieved an overall pressure ratio of 7.2 near design speed with an equivalent weight flow of 28.6 lb/sec of air per square foot of frontal area.

NACA TN 4253

DESIGN AND TESTS OF A SIX-STAGE AXIAL-FLOW COMPRESSOR HAVING A TIP SPEED OF 550 FEET PER SECOND AND A FLAT OPERATING CHARACTERISTIC AT CONSTANT SPEED. Willard R. Westphal and John W. Maynard, Jr. June 1958. 57p. diagrs., photos., tabs. (NACA TN 4253)

The six-stage axial-flow compressor was designed for a constant power input per pound of flow with a design specific weight flow of 21.3 pounds per second per square foot of frontal area at atmospheric discharge with a stagnation-pressure ratio of 3.25 and an inlet hub-tip radius ratio of 0.7. Several configurations having different blade setting angles and solidities were tested. The tests showed that the design flow, pressure ratio, and flat stagnation-pressure ratio as a function of weight flow were obtained at a peak efficiency of 82.8 percent.

NACA TN 4257

RESULTS OF AN EXPERIMENTAL INVESTIGATION OF SMALL VISCOUS DAMPERS. Milton A. Silveira, Domenic J. Maglieri, and George W. Brooks. June 1958. 49p. diagrs., photos. (NACA TN 4257)

Experimental results on the damping characteristics of small viscous dampers are presented. Several types of fluid-displacement and viscous-shear dampers for varying physical and fluid properties were tested. Descriptions of test devices are also presented.

NACA TN 4258

A NUMERICAL METHOD FOR EVALUATING WAVE DRAG. Maurice S. Cahn and Walter B. Olstad. June 1958. 13p. diagrs., tabs. (NACA TN 4258)

A numerical method for evaluating Von Kármán's wave-drag equation was developed and applied to four analytical bodies of revolution. It was concluded that the numerical method will yield results well within the accuracy of linearized theory. The method may be set up easily for a desk calculator or an electronic computer.

NACA TN 4264

INTERNAL CHARACTERISTICS AND PERFORMANCE OF SEVERAL JET DEFLECTORS AT PRIMARY-NOZZLE PRESSURE RATIOS UP TO 3.0. Jack G. McArdle. June 1958. ii, 107p. diagrs., photos., tabs. (NACA TN 4264)

Several model jet deflectors (devices which change the direction of resultant jet thrust) were tested in quiescent air. The deflectors (swiveled nozzles, auxiliary nozzles, and mechanical deflectors) were designed to be adaptable to conventional turbojet exhaust systems and produced side force as high as 43 percent of the undeflected jet thrust. Analytical expressions relating the performance of each type deflector with significant design variables are also presented.

NACA TN 4266

STUDIES OF OH, CO, CH, AND C_2 RADIATION FROM LAMINAR AND TURBULENT PROPANE-AIR AND ETHYLENE-AIR FLAMES. Thomas P. Clark. June 1958. 23p. diagrs., photos. (NACA TN 4266)

OH, CO, CH, and C_2 radiations from propane-air and ethylene-air flames were isolated with a monochromator, and the variation of emitter intensity with equivalence ratio was determined. The ratio of C_2 and CH radiation intensities was found to be a good index of the equivalence ratio in the flame. Turbulent open flames burning on tubes were found to become leaner near the base, but appeared to be burning at the metered equivalence ratio in the turbulent brush. The amount of radiation given off by the flame per unit rate of fuel consumption decreased with increasing average gas-flow velocities and Reynolds numbers, but this decrease could not be accounted for by admixing of the secondary air with the turbulent flame brush.

NACA TN 4272

USE OF THE COANDA EFFECT FOR OBTAINING JET DEFLECTION AND LIFT WITH A SINGLE FLAT-PLATE DEFLECTION SURFACE. Uwe H. von Glahn. June 1958. 49p. diagrs., tabs. (NACA TN 4272)

Performance characteristics similar to those for a flap immersed in an airstream were obtained in quiescent air for nozzle-deflection-plate configurations using the Coanda effect for achieving jet deflection and vertical lift. With a simple flat-plate deflection surface the optimum ratio of lift to undeflected thrust follows a sine function with plate deflection angle. Because of jet detachment from the deflection plate, the configurations studied were limited to specific deflection angles depending on nozzle height. An empirical relation was derived for predicting the required plate length in terms of nozzle height for achieving optimum performance at a given deflection-plate angle and pressure ratio.

NACA TN 4273

ON PAIRS OF SOLUTIONS OF A CLASS OF INTERNAL VISCOUS FLOW PROBLEMS WITH BODY FORCES. Simon Ostrach and Lynn U. Albers. June 1958. 21p. diagrs., tabs. (NACA TN 4273)

In previous analyses of fully developed combined forced- and natural-convection flows, a few examples were presented of two distinct states of flow and heat transfer which were obtained for a given set of conditions if the frictional heating was taken into account. This report discusses these pairs of solutions in greater detail and shows how the solutions are affected by systematic variations of the basic physical parameters. It is also shown that a critical set of parametric values exists beyond which no fully developed solutions can be found.

NACA TN 4275

DYNAMIC STABILITY OF VEHICLES TRAVERSING ASCENDING OR DESCENDING PATHS THROUGH THE ATMOSPHERE. Murray Tobak and H. Julian Allen. July 1958. (i), 35p. diagrs. (NACA TN 4275)

An analysis is given of the oscillatory motions of vehicles which traverse ascending and descending paths through the atmosphere at high speed. The specific case of a skip path is examined in detail, and this leads to a form of solution for the oscillatory motion which should recur over any trajectory. The distinguishing feature of this form is the appearance of the Bessel rather than the trigonometric function as the characteristic mode of oscillation.

NACA TN 4278

APPLICATION OF STATISTICAL THEORY TO BEAM-RIDER GUIDANCE IN THE PRESENCE OF NOISE. II - MODIFIED WIENER FILTER THEORY. Elwood C. Stewart. June 1958. (i), 48p. diagrs., tabs. (NACA TN 4278. Supersedes RM A55E11a)

An application has been made of Newton's modification of Wiener filter theory to optimize a beam-rider guidance system operating in the presence of glint noise. Results indicate that when the operation of the system is restricted to practical linear ranges, the minimum error attained from this theory closely approaches that for the Wiener theory. The system transfer functions and error performance against noise are given. Requirements on control deflection rates, circuit voltages, and servoenergy are discussed.

NACA TN 4283

FULL-SCALE WIND-TUNNEL TESTS OF A 35° SWEPTBACK-WING AIRPLANE WITH BLOWING FROM THE SHROUD AHEAD OF THE TRAILING-EDGE FLAPS. William H. Tolhurst, Jr. July 1958. 40p. diagrs., photos., tabs. (NACA TN 4283)

Data are presented showing the effect of flap position relative to the blowing nozzle on the air-flow requirements for boundary-layer control on flaps deflected from 45° to 75° at a Reynolds number of 7.5×10^{6}. A direct comparison of shroud blowing and flap blowing is shown for a plain flap configuration. Also presented are data showing the effect on the air-flow requirements of spacers in the nozzle, discontinuities on the flap upper surface, and of sealing the slot when the flap was in the single-slotted flap configuration.

NACA TN 4289

BOUNDARY-INDUCED DOWNWASH DUE TO LIFT IN A TWO-DIMENSIONAL SLOTTED WIND TUNNEL. S. Katzoff and Raymond L. Barger. June 1958. 31p. diagrs. (NACA TN 4289)

A solution has been obtained for the complete tunnel-interference flow for a lifting vortex in a two-dimensional slotted tunnel. Curves are presented for the longitudinal distribution of tunnel-induced downwash angle for various values of the boundary openness parameter and for various heights of the vortex above the tunnel center line. Some quantitative discussion is given of the use of these results in calculating the tunnel interference for three-dimensional wings in rectangular tunnels with closed side walls and slotted top and bottom.

NACA TN 4290

A FUSELAGE ADDITION TO INCREASE DRAG-RISE MACH NUMBER OF SUBSONIC AIRPLANES AT LIFTING CONDITIONS. Richard T. Whitcomb. June 1958. 38p. diagrs., photos., tab. (NACA TN 4290)

The addition of fuselage volume on the top of the forward portion of the fuselage for the purpose of increasing the drag-rise Mach number of subsonic airplanes at lifting conditions is investigated. The additions have been designed on the basis of the area rule and other important considerations to provide greater practicability of application compared with shapings previously investigated. The addition increased the drag-rise Mach number by an increment of approximately 0.03 for a configuration having a wing with moderate thickness and 35° of sweepback at a lift coefficient of 0.3. A lesser increase was obtained for a configuration with a thicker wing. The additions increase the nonlinearities of the variations of pitching moment with lift.

CURRENT NACA RESEARCH REPORTS

NACA TN 4291

AN EVALUATION OF EFFECTS OF FLEXIBILITY ON WING STRAINS IN ROUGH AIR FOR A LARGE SWEPT-WING AIRPLANE BY MEANS OF EXPERIMENTALLY DETERMINED FREQUENCY-RESPONSE FUNCTIONS WITH AN ASSESSMENT OF RANDOM-PROCESS TECHNIQUES EMPLOYED. Thomas L. Coleman, Harry Press, and May T. Meadows. July 1958. ii, 74p. diagrs., photo., tabs. (NACA TN 4291)

Flight test measurements on a large swept-wing bomber airplane through rough air at altitudes of 5,000 and 35,000 feet are analyzed in order to determine the effects of airplane flexibility on wing bending and shear strains. For this purpose, the power spectra of the strain responses and the frequency-response functions for the strain responses to vertical gust disturbances are determined and compared with the strain responses for a quasi-rigid airplane. The measured power spectra and frequency-response functions are subject to distortion and statistical sampling errors from a variety of sources. A general analysis of the reliability of such results is presented and methods of estimating the distortions and sampling errors are developed. These methods are applied to the interpretation of the test results.

NACA TN 4292

LOCAL INSTABILITY OF THE ELEMENTS OF A TRUSS-CORE SANDWICH PLATE. Melvin S. Anderson. July 1958. 21p. diagrs., photo. (NACA TN 4292)

The charts presented give the compressive buckling coefficients for a single-truss-core and a double-truss-core sandwich plate. These charts cover a wide range of sandwich proportions and may be used for sandwiches with unequal faces. They apply to in-plane compressive loads acting parallel or perpendicular to the core direction or for various combinations of these loads.

NACA TN 4293

SPECIAL BODIES ADDED ON A WING TO REDUCE SHOCK-INDUCED BOUNDARY-LAYER SEPARATION AT HIGH SUBSONIC SPEEDS. Richard T. Whitcomb. June 1958. 48p. diagrs., photos. (NACA TN 4293)

The basic test configuration had a relatively thick 35° sweptback wing of aspect ratio 7.05 mounted on a contoured fuselage. Studies of the boundary-layer flow indicate that addition of the bodies resulted in a significant lessening of the separation on this configuration at high subsonic Mach numbers. Marked reductions in drag and pitch-up were associated with the improved flow. With an increase in sweep of the wing to 40°, the effectiveness of the added bodies in improving the drag and pitching-moment characteristics was increased.

NACA TN 4295

REFLECTION AND TRANSMISSION OF SOUND BY A SLOTTED WALL SEPARATING TWO MOVING FLUID STREAMS. Raymond L. Barger. June 1958. 14p. diagrs. (NACA TN 4295)

The acoustics problem discussed is related to the aerodynamic problem of determining the tunnel-wall interference on an oscillating airfoil in a slotted-throat wind tunnel in that the same boundary condition is involved with one of the two streams at the boundary having zero velocity. In the analysis the wall with discrete slots is replaced by an equivalent homogeneous boundary.

NACA TN 4296

COMPRESSIVE STRENGTH AND CREEP OF 17-7 PH STAINLESS-STEEL PLATES AT ELEVATED TEMPERATURES. Bland A. Stein. July 1958. 33p. diagrs., photos., tabs. (NACA TN 4296)

Compressive strength test results from room temperature to $1,000^{\circ}$ F and compressive creep test results from 700° F to $1,000^{\circ}$ F are presented for plates of 17-7 PH stainless steel, Condition TH 1,050, which were edge-supported in V-groove fixtures. Plate width-thickness ratios range from 15 to 60. Master curves are presented which show the combinations of average stress, temperature, and time which produce given amounts of creep strain or failure of the plates and which facilitate interpolation of the test results. The test results are compared with plate strengths and creep failure stresses determined from semiempirical approximations.

NACA TN 4298

EXPLORATORY WIND-TUNNEL INVESTIGATION TO DETERMINE THE LIFT EFFECTS OF BLOWING OVER FLAPS FROM NACELLES MOUNTED ABOVE THE WING. John M. Riebe and Edwin E. Davenport. June 1958. 19p. diagrs., tab. (NACA TN 4298)

An exploratory investigation, in which high-pressure air was blown over single and double slotted flaps from externally supported steel-pipe nacelles above the wing to simulate jet-engine exhaust, has been conducted on a model with a delta wing of aspect ratio 3. The jet-momentum-coefficient range was from 0 to 3.0 and the model angle of attack was 0°. Results of the limited investigation show that jet-circulation lift coefficients greater than the jet reaction alone were produced.

CURRENT NACA RESEARCH REPORTS

NACA TN 4299

EFFECTS OF FABRICATION-TYPE ROUGHNESS ON TURBULENT SKIN FRICTION AT SUPERSONIC SPEEDS. K. R. Czarnecki, John R. Sevier, Jr., and Melvin M. Carmel. July 1958. 15p. diagrs. (NACA TN 4299)

The results of this investigation indicate that the effects of both Reynolds number and Mach number can be correlated on the basis of changes in flow characteristics within the inner parts of the boundary layer. Consequently, increasing the unit Reynolds number has a detrimental effect and increasing Mach number has a powerful alleviating effect on drag due to surface roughness. The correlation of the effects of changes in roughness height or shape awaits a more comprehensive analysis than was attempted in this paper. Further investigation must be made of the effects of roughness sweep and possibly mutual interference effects.

NACA TN 4301

EFFECTS OF BOUNDARY-LAYER DISPLACEMENT AND LEADING-EDGE BLUNTNESS ON PRESSURE DISTRIBUTION, SKIN FRICTION, AND HEAT TRANSFER OF BODIES AT HYPERSONIC SPEEDS. Mitchel H. Bertram and Arthur Henderson, Jr. July 1958. 33p. diagrs. (NACA TN 4301)

Results are presented of an investigation to determine the effect of boundary-layer displacement and leading-edge bluntness on surfaces in hypersonic flow. The presence of the boundary layer and the blunt leading edge induce pressure gradients which in turn affect the skin friction and heat transfer to the surface. Methods for predicting these phenomena on two-dimensional surfaces are given and a brief review of recent three-dimensional results is presented.

NACA TN 4303

MEASUREMENTS AND POWER SPECTRA OF RUNWAY ROUGHNESS AT AIRPORTS IN COUNTRIES OF THE NORTH ATLANTIC TREATY ORGANIZATION. Wilbur E. Thompson. July 1958. 85p. diagrs. (NACA TN 4303)

Measurements of runway roughness obtained by a profile-survey method are presented. A variety of runway lengths or sections and degrees of roughness were measured. The results are presented as elevation profiles of the runways surveyed and in the form of power spectra.

NACA TN 4311

PRANDTL NUMBER EFFECTS ON UNSTEADY FORCED-CONVECTION HEAT TRANSFER. E. M. Sparrow and J. L. Gregg. June 1958. 14p. diagrs., tab. (NACA TN 4311)

An analysis is made for laminar forced-convection heat transfer on a flat plate with unsteady surface temperature. The deviation of the instantaneous heat-transfer rate from the quasi-steady value is computed. Results are obtained for Prandtl numbers in the range 0.01 to 10. The deviations from quasi-steady heat transfer increase markedly with increasing Prandtl number. The findings reported here should apply approximately in the entrance region of ducts and should also provide an upper bound on deviations from turbulent quasi-steady heat transfer.

NACA TN 4330

FLOW INDUCED BY A ROTOR IN POWER-ON VERTICAL DESCENT. Walter Castles, Jr., Georgia Institute of Technology. July 1958. 25p. diagrs., tabs. (NACA TN 4330)

Approximate equations are derived for the induced power required and blade loading of a lifting rotor operating in the power-on vertical-descent range. The approximate relations, which are based upon certain assumptions as to the nature of the flow pattern, yield, for the induced power variation, results which are in general agreement with available data.

NACA TN 4340

WIND-TUNNEL INVESTIGATION OF THE HIGH-SUBSONIC STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF SEVERAL WING-BODY CONFIGURATIONS DESIGNED FOR HIGH LIFT-DRAG RATIOS AT A MACH NUMBER OF 1.4. Paul G. Fournier. July 1958. 42p. diagrs., photo., tab. (NACA TN 4340)

The Mach number range was 0.60 to 0.95 with a corresponding Reynolds number of 2.0×10^6 to 3.3×10^6 based on mean aerodynamic chord. The basic highly swept (approximately 60° at c/4) wing had a taper ratio of 0.167, an aspect ratio of 2.91, and thin NACA 65A-series airfoil sections. Other wings, of the same plan form, had twist and camber and twist. All bodies were of elliptical cross section; the basic body had a Sears-Haack area distribution and the others had indentation for a Mach number of 1.4. The maximum angle-of-attack range was from -2° to 22°.

CURRENT NACA RESEARCH REPORTS

NACA TN 4342

FLIGHT MEASUREMENTS OF THE VIBRATORY BENDING AND TORSIONAL STRESSES ON A MODIFIED SUPERSONIC PROPELLER FOR FORWARD MACH NUMBERS UP TO 0.95. Thomas C. O'Bryan. June 1958. 17p. diagrs., photos. (NACA TN 4342)

Vibratory bending stresses, measured in flight, on a modified supersonic propeller were low in relation to the strength of the material. The vibratory torsional stresses did not exceed ±1,000 pounds per square inch.

Aeronautical Research Council (Gt. Brit.)
LOW-SPEED TESTS ON 45-DEG SWEPT-BACK WINGS. PART I. PRESSURE MEASUREMENTS ON WINGS OF ASPECT RATIO 5. J. Weber and G. G. Brebner. PART II. BALANCE AND PRESSURE MEASUREMENTS ON WINGS OF DIFFERENT ASPECT RATIOS. D. Küchemann, J. Weber, and G. G. Brebner. 1958. 89p. diagrs., tabs. ARC R & M 2882; ARC 13,655; ARC 14,139. Supersedes RAE Report Aero 2374 and RAE Report Aero 2419. (Ask for N-5278Y*)

Contains results of pressure measurements on three 45° sweptback wings with constant chord and AR = 5, over an angle-of-attack range up to 10°. Chordwise and spanwise lift distributions are given, mostly near the center where, on two of the wings, modifications had been made to the section shape. It was found that altering the thickness distribution in the center did not affect the loading but that approximately straight isobars could be obtained at values of C_L below about 0.1. By the incorporation of twist and camber in the central part the distortion of the lift distribution in the center could be avoided at one particular incidence, and thus the same chordwise distribution obtained over most of the span. The second part contains balance and pressure measurements on constant-chord wings of 45° sweepback and provides data on aspect ratio wings of 2, 3, 5, and infinity.

WIND-TUNNEL INTERFERENCE EFFECTS ON MEASUREMENTS OF AERODYNAMIC COEFFICIENTS FOR OSCILLATING AEROFOILS. W. P. Jones. 1958. 12p. diagrs., tabs. ARC R & M 2786. Supersedes ARC 13,411; FM 1478; S & C 2433; 0.894. (Ask for N-14283X*)

A theory is developed for estimating the effect of wind-tunnel walls on measured values of aerodynamic coefficients for two-dimensional airfoils oscillating in an incompressible fluid. The case of an airfoil describing translational and pitching oscillations in a wind tunnel of rectangular cross section is considered, and it is shown that the damping derivatives associated with the pitching degree of freedom are very sensitive to wall effects when the frequency parameter for the motion is small, and when the axis of oscillation is not at, or near, quarter chord. When the axis is at quarter chord, the pitching-moment damping derivative is hardly affected by the presence of the tunnel walls.

OSCILLATING WINGS IN COMPRESSIBLE SUBSONIC FLOW. W. P. Jones, National Physical Laboratory. 1957. 18p. diagrs., tab. ARC R & M 2855. Supersedes ARC 14,336; 0.961; S & C 2560. (Ask for N-21486X*)

The problem of estimating flutter and stability derivatives for wings of finite span describing simple harmonic oscillations in compressible flow is considered. It is shown that the problem can be reduced to a similar one for an equivalent wing in incompressible flow. The lateral dimensions of the equivalent wing are $\sqrt{(1 - M^2)}$ times those of the original wing and the frequency of oscillation is increased by the factor $(1 - M^2)^{-1}$ where M denotes the Mach number of the compressible flow. The mode of oscillation is different but related to that of the original wing and leads to a more complicated condition for tangential flow.

Aeronautical Research Council (Gt. Brit.)
A COMPARISON OF THE MEASURED AND PREDICTED FLUTTER CHARACTERISTICS OF A SERIES OF DELTA WINGS OF DIFFERENT ASPECT RATIOS. H. Hall and E. W. Chapple. 1958. 8p. diagrs., photos., tab. ARC R & M 3071; ARC 18,206. Supersedes RAE Report Structures 180. (Ask for N-40041X*)

This report gives the results of tests to investigate the aerodynamic effects of aspect ratio on the flutter of delta wings that are virtually rigid but are flexibly supported at the root. A function representing the aerodynamic effects of aspect ratio on wing flutter speeds is derived from the experiments. Flutter calculations are made using this function as a correction to the derivatives obtained from two-dimensional theory, and there is good agreement between measured and calculated results. Calculations are also made using derivatives obtained from three-dimensional theory, but the agreement between measured and calculated results is poor.

Aeronautical Research Council (Gt. Brit.)
THE EFFECT OF WING TORSION ON AILERON-TAB FLUTTER. H. Hall. 1958. 19p. diagrs., tab. ARC R & M 3072; ARC 18,724. Supersedes RAE Report Structures 203. (Ask for N-44951X*)

This paper gives the results of an investigation into the effects of wing torsion in a ternary-type spring-tab flutter. The results presented are for a series of calculations on an idealized system having degrees of freedom in wing pitch, rotation of the control surface, and rotation of the tab; the pitching degree of freedom is spring restrained and is intended to represent wing torsion. The tab is restrained as a trim tab or pure aerodynamic servotab, but the results are expected to apply qualitatively to a spring tab. A comparison is made between these results and those of earlier investigations into a similar problem by Wittmeyer and Wittmeyer and Templeton, where the main surface mode considered was one of vertical translation to represent wing bending.

SUPERSONIC BANGS. PART II. P. Sambasiva Rao. September 12, 1955. 22p. diagrs. ARC 17,842; FM 2295. (Ask for N-47024X*)

The nonlinear theory of supersonic bangs, obtained in part I for a body accelerating along a straight path, is extended to include curved paths. The basic theory remains the same. The important parameter, which appears in the theory, is the acceleration component along the ray, the rays being lines drawn from points on the flight path at an angle $\cos^{-1}(1/M)$ with the direction of motion. It is found that the only essential effect of the curvature of the path is in the modification of this acceleration component to include a term due to the transverse acceleration. With this modification the main results are formally the same as in part I. Finally, the theory is compared and contrasted with the recent work by Warren.

Aeronautical Research Council (Gt. Brit.)
REGULARITIES IN CREEP AND HOT FATIGUE DATA. PART II. K. F. A. Walles and A. Graham. 1958. 141p. diagrs., tabs. ARC CP 380. (Ask for N-48178X*)

A previously given theory, which was extended in part I, suggests that (for a single form of loading) strain ϵ is related to stress σ, time t, and temperature T by a sum of terms of the form $C\sigma^{\beta}\emptyset^{\kappa}$ where $\emptyset = t(T' - T)^{-A}$ that the constant A is the same for all terms and a range of materials, and that the ratios β/κ take values from the sequence 2^n. In the present part II, the theory is compared with 103 sets of published creep rupture, creep rate, and hot-fatigue data relating mainly to alloys of the Fe, Ni, Cr, Co system of 44 different compositions. The results of all analyses are given in detail in the figures and tables. A statistical assessment of the extent of agreement of the theory with the data is given with reference to the number of free constants used.

Aeronautical Research Council (Gt. Brit.)
THE WAVE DRAG OF NON-LIFTING COMBINATIONS OF THIN WINGS AND "NON-SLENDER" BODIES. L. M. Sheppard. 1958. 17p. diagrs. ARC R & M 3076; ARC 19,319. Supersedes RAE Tech. Note Aero 2496. (Ask for N-48943X*)

The methods of wave-drag estimation known as the area rule and transfer rule are restricted to non-lifting combinations of thin wings and slender bodies. The Lomax-Heaslet multipole method is applicable to configurations with "nonslender" fuselages, represented by an axial distribution of multipoles. However, it is not entirely satisfactory and an alternative multipole method is presented here. This is based upon the assumption, fundamental to the area rule and the transfer rule, that the effect on the wave drag of the interference velocity potential, due to the interaction between the exposed wing and the fuselage, is negligible. An investigation of the validity of this fundamental assumption based on existing theoretical and experimental results is given.

ACOUSTIC EFFECTS IN THE VIBRATIONS OF STRUCTURES. J. Foxwell and R. E. Franklin. August 29, 1957. 10p. diagrs. ARC 19,495; LA 41. (Ask for N-60873*)

It is shown that the response of a simple system can be considerably modified by the effects of an enclosed volume of air. The effects appearing in the simple one-dimensional model chosen do in fact appear in the case of a cylinder and this case will be dealt with in another paper. Broadly speaking it can be said that the effects are such that expected resonances may not occur and unexpected ones may be of significance. It is emphasized that no account is taken of structural damping; it is probable that although its effects may modify the amplitude of the resonances, the general characteristics of the problem will remain.

THE GENERATION OF SECONDARY VORTICITY IN THE FLOW OVER A HEMISPHERE DUE TO DENSITY GRADIENT AND SHEAR. W. R. Hawthorne and Moira E. Martin, University of Cambridge. May 26, 1955. 20p. diagrs., photos. ARC 17,654; FM 2257. (Ask for N-60874*)

When an inviscid fluid with a slight vertical variation of stagnation pressure and density flows over an obstacle lying on a horizontal plane a vorticity component in the direction of flow appears. An expression for this secondary vorticity is obtained on the assumption that the velocity and density gradients and gravitational effects are small enough for the flow to be regarded as a small perturbation of the potential flow about the obstacle. The obstacle is a hemisphere with its flat surface on the plane. It is, for instance, a hemispherical rock or hill standing in flat surroundings.

NOTE ON THE EXTENSION OF EVVARD'S METHOD TO WINGS WITH "SUBSONIC" LEADING EDGES MOVING AT SUPERSONIC SPEEDS. G. J. Hancock, Queen Mary College. June 29, 1955. 25p. diagrs. ARC 17,716; FM 2268. (Ask for N-60878*)

Evvard's technique is applied to the problem of a thin finite wing moving at a supersonic speed when the leading edge is "subsonic" and is developed in two methods. The first method is one in which the relationship between the pressure loading and the integrals of the downwash over the wing surface is extended as far as possible and which has to be computed numerically. The other method is one in which approximations are made for the upwash fields in the neighborhood of the leading edge, leading to a series of standard integrals for the estimation of the pressure loading. The second method is applied to the pressure loading on a flat plate triangular wing and cropped delta wing, and the application to more general shapes is discussed.

ON THE THEORY OF SOURCE-FLOW FROM AEROFOILS. L. C. Woods, University of Sydney, Australia. July 22, 1955. 17p. diagrs. ARC 17,766; FM 2280. (Ask for N-60880*)

An exact theoretical treatment of the influence of sources of fluid on and within two-dimensional airfoils is developed. In the case of a source placed within an airfoil the fluid is ejected through a duct, the shape of which is taken into account in the theory. The theory is given for incompressible flow but it could be extended to deal with linearized subsonic compressible flow. Formulas for the thrust, lift, and moment are derived from Blasius' theorem. The case of the "directed" source receives attention, and the influence of the angle of ejection is determined.

AN INVESTIGATION OF THE EFFECTS OF THICKNESS, CAMBER AND NOSE RADIUS ON THE PERFORMANCE OF JET-FLAPPED AEROFOILS. J. A. Beasley. October 1957. 18p. diagrs., tab. RAE Tech. Note Aero 2534. (Ask for N-60884*)

Pressure distributions are calculated by Küchemann's method for six airfoils with jets blowing over deflected trailing-edge flaps. Some inaccuracy has been incurred by making approximations in the calculation but it has been possible to study qualitatively the efficacy of thickness, camber, and nose radius in preventing flow separation near the nose. The conclusions could thus be used to select airfoils suitable for use with jet flaps. The effects of jet deflection angle and of incidence are also discussed.

THE ABSOLUTE MEASUREMENT OF RATE OF FLOW OF LARGE QUANTITIES OF GAS. W. F. Cope, National Physical Laboratory. June 20, 1955. 4p. ARC 17,691; EA 415; FM 2421.
(Ask for N-60889*)

The accuracy of measurement of flow rates (from ±1 percent) for large quantities of gas has not changed for 40 years. The principal causes of error are temperature inequalities and velocity measurements in turbulence. An investigation with modern techniques seems not to exist and is overdue.

IMPORTANCE OF SHAPE OF STRINGER SECTION IN PRESSURE-CABIN DESIGN. D. Williams. March 1958. 7p. RAE Tech.Note Structures 234.
(Ask for N-60892*)

It is shown that the effectiveness of the stringers in restricting the radial expansion of the cabin skin between frames depends upon the shape of the stringer cross section. Stringer sections in which the inward radial pull of the frames is offset from the shear center of the stringer section twist under the pull, so that the amount of stringer bending stiffness brought into action may well be only one-thousandth part of the potential stiffness. Channel, angle, and L sections in which the web and flanges of the l are at right angles, come under this category. Top-hat sections function admirably in this respect.

FACTORS GOVERNING THE IGNITION DELAY OF GASEOUS FUELS. R. E. Miller. March 1958. 37p. diagrs., photo., tab. NGTE Report R.216.
(Ask for N-61282*)

The variation of ignition delay with temperature in a new laboratory apparatus has been investigated. In addition to temperature the concentrations of fuel (calor gas), oxygen, and steam have been varied and their effects measured. The effect of scale has been shown to be negligible by comparison with Mullins' data for calor gas in a 6-inch duct. The results have been compared with those found by other workers and found to differ considerably from those reported at NACA. A reason for this difference is suggested. Various views on the nature of spontaneous ignition are considered and it is found that all the observed facts can be explained in terms of a second-order kinetic law. It is pointed out that a reaction rate equation based on a detailed kinetic mechanism reduces to the simple second-order equation in certain cases.

SOME EXPERIMENTS ON THE SHEARING OF FINE METAL FOILS AT VERY HIGH SPEEDS. B. J. Brinkworth. December 1957. 21p. diagrs., photos. RAE Tech.Note Mech.Eng.250. (Ask for N-61285*)

Exploratory tests are described in which the work done in shearing fine aluminum and copper foils was measured at cutting speeds up to 120 ft per sec. The results indicate an increase in energy to fracture with increasing speed up to a point at which thermal softening is believed to predominate. Subsequently, the energy curve declines. Both the materials tested exhibit a marked size effect. From the results obtained and an examination of related work, hypothetical relations are put forward showing the anticipated variation of fracture energy over a wide range of speed.

Aeroplane and Armament Experimental Establishment (Gt. Brit.). A REDUCTION METHOD FOR THE FORWARD TAKE-OFF OF A SINGLE ROTOR HELICOPTER. M. C. Neale. December 20, 1957. 20p. diagrs. AAEE/Res/297. (Ask for N-61290*)

A method is given for reducing observed helicopter take-off performance measurements to standard conditions and for estimating the effect of changes in wind speed, engine power, all up weight, and climb speed. The correction for wind changes is obtained from a consideration of the relative air velocities during the different stages of take-off. By the use of charts, changes in the other variables are related to changes in the value of the thrust/weight ratio which are used with further charts to determine the corrected flight path.

UNSTEADY VISCOUS FLOW PAST A CIRCULAR CYLINDER. R. B. Payne, University of Manchester. November 26, 1957. 7p. diagrs. ARC 19,694; FM 2618. (Ask for N-61402*)

A numerical solution has been obtained for the starting flow of a viscous fluid past a circular cylinder at Reynolds numbers 40 and 100. The method used is the step-by-step forward integration in time of Helmholtz's vorticity equation. The advantage of working with the vorticity is that calculations can be confined to the region of nonzero vorticity near the cylinder. Besides the general features of the flow, including the formation of the eddies attached to the rear of the cylinder, the drag has been calculated. At R = 40 the drag on the cylinder decreases with time to a value very near that for the steady flow.

DEPARTURE FROM DISSOCIATION EQUILIBRIUM IN A HYPERSONIC NOZZLE. K. N. C. Bray, University of Southampton. March 17, 1958. 30p. diagrs., tabs. ARC 19,983; FM 2656; EA 622, CF 433; TP 571. (Ask for N-61403*)

The flow of an ideal dissociating gas through a nearly conical nozzle has been examined. The results suggest that deviations from dissociation equilibrium will occur over a wide range of conditions and that lack of equilibrium may be expected in the working sections of hypersonic wind tunnels and shock tubes. Although the flow behind a normal shock wave in such a wind tunnel will not be greatly affected by it, the stand-off distance in front of a blunt model may be quite sensitive to deviations from equilibrium.

STRUCTURES OF MINIMUM WEIGHT: THE BASIC THEORY OF DESIGN APPLIED TO THE BEAM UNDER PURE BENDING. H. L. Cox. January 10, 1958. 9p. diagrs. ARC 19,785; Strut. 2036. (Ask for N-61409*)

At each end of the beam of length $2l$ the moment M is applied by means of a pair of concentrated loads $\pm M/2d$ acting in parallel lines 2d apart. It is first demonstrated that if $l/d > 4$ the optimum structure is appreciably lighter than a straight beam of constant depth 2d, and by synthesis of elementary substructures it is then shown that when $l/d > 20$ the optimum structure must weigh less than half the straight beam. By application of the basic theory of design due to Clerk Maxwell and A. G. M. Michell what is thought to be the true optimum structures is found and compared with a practical 14-bar framework. For values of $l/d > 10$ at least 35 percent of the weight of a parallel beam is unnecessary. A thin wing should not be continued as a parallel beam through the fuselage.

SOME CREEP AND TENSILE PROPERTIES OF A CORROSION RESISTING STEEL TO BRITISH STANDARDS SPECIFICATION S. 80, AT 22° C, 250° C, 400° C, AND 550° C. R. A. Whittaker. December 1957. 17p. diagrs. RAE Tech. Note Met. 280. (Ask for N-61411*)

Constant-load tensile creep tests and short-term tensile tests have been made on a hardened and tempered corrosion-resisting steel to B.S.S. S.80, at room temperature (22° C), 250° C, 400° C, and 550° C. At 22° C and 250° C the creep curves indicate a rapid increase in strain followed by a relatively small creep rate. The effect of applying 0.1 percent prestrain at room temperature prior to creep testing at 250° C is to reduce the amount of strain on loading by approximately 60 percent. The shape of the creep curves at 22° C and 250° C precludes the more usual

BRITISH REPORTS

types of assessment of properties but for comparative purposes table IV showing increase of strain with time is included. At 400° C and 550° C more "normal" types of creep curves have made possible a limited amount of engineering data.

Aeroplane and Armament Experimental Establishment (Gt. Brit.). SOME EXPERIMENTS WITH A MODEL JET FLAP IN A CENTRIFUGAL FIELD. D. A. Wilkinson. March 20, 1958. 14p. diagrs., photos. AAEE/Res/296. (Ask for N-61542*)

The possible application of the jet-flap principle to helicopter rotors has aroused interest as to the influence of a centrifugal field on the phenomenon, particularly with regard to any reduced effectiveness resulting, for example, from distortion or rupture of the jet sheet. Brief tests have been made with a model jet flap to determine any marked change between the lift characteristics measured in a wind tunnel and those measured on a whirling arm up to 15 "g." At constant thrust coefficient, a decrease of lift coefficient with increased spanwise acceleration was noted, the rate of decrease being approximately zero at 15 "g." A description is given of the balance used to measure the lift forces on the model while being whirled.

THE CALCULATION OF LIFT SLOPES, ALLOWING FOR BOUNDARY LAYER, WITH APPLICATIONS TO THE R.A.E. 101 AND 104 AEROFOILS. D. A. Spence and J. A. Beasley. February 1958. 28p. diagrs., tab. RAE Report Aero 2598.
(Ask for N-61546*)

The need to know two-dimensional low-speed characteristics accurately in designing sweptback wings for transonic aircraft has led to a revival of interest in calculations of the loss of lift below the ideal flow value caused by the boundary layer. The existing methods for performing this calculation have now been reduced to a straightforward routine. This is sufficiently sensitive for coefficients to be evaluated at rather small incidences, for example, $\alpha = 2^{\circ}$, for which the boundary-layer part of the calculation is tractable; from these results the lift at higher incidences may be estimated. The method has been applied to RAE 101 and 104 sections of 6, 10, and 15 percent thickness at $R = 10^6$, 10^7, and 10^8 with a wide range of transition positions.

Royal Aircraft Establishment (Gt. Brit.)
ON THE EXTRACTION OF STABILITY DERIVATIVES FROM FULL SCALE FLIGHT DATA. J. K. Zbrozek. April 1958. 29p. diagrs. RAE Tech.Note Aero 2559. (Ask for N-61547*)

The information obtained from longitudinal response measurement is insufficient to evaluate the three basic derivatives: m_w, m_q, and $m_{\dot{w}}$; only lift slope can be obtained. The values of m_w and m_q can be obtained from trim curves of η versus C_L for rectilinear and curvilinear flights. This limits the measurements of these derivatives to zero frequency, but it is believed this is only a minor disadvantage. Theoretically the basic seven lateral derivatives can be obtained from the measured transient responses to control inputs. With an additional effort the control derivatives can be evaluated also. Due to limited accuracy of flight measurements the extraction of l_r, and especially n_p, is extremely difficult. The problem of recording aircraft responses with sufficient accuracy is briefly discussed with the unpleasant conclusion that the basic instruments (gyro, accelerometer, yawmeter) at present available, are far below the standard required for dynamic measurements of stability of present and future aircraft.

Advisory Group for Aeronautical Research and Development. GENERAL REFLECTIONS ON THE SAFETY OF MATERIALS AND STRUCTURES. (Reflexions generales sur la securite des materiaux et des structures.) E. Marcel Prot. (Presented at 6th meeting of AGARD Structures and Materials Panel, Paris, November 4-8, 1957.) November 1957. iv, 11p. (French text.) AGARD Report 151. (Ask for CN-61705)

The notion of safety gets clearer when the notions of frequency and probability are taken into account and when the nature of the accidents, the risks of which one intends to reduce, and the importance of their consequences are considered. A safety coefficient can adequately be selected only through the striking of a balance which takes into account the various

MISCELLANEOUS

economic factors varying with this coefficient. The selection of a material and the design of a structure can only be effected after tests so numerous as to allow the assessment of the risks of damage of the structure considered. A test assumes value only if it can be summarized by the mean value x_n and the mean quadratic divergence y_n of the results obtained from a given number of tests. These figures allow calculation of mean value x and of mean quadratic divergence y of the overall material concerned.

Metallurgical Research Laboratories, Syracuse University Research Institute. TENSION, COMPRESSION AND FATIGUE TESTS OF SEVERAL ALLOYS TO DETERMINE THEIR SUITABILITY AS BEARING MATERIALS. R. J. Sell and G. Sachs. Interim Technical Report prepared for NACA under NACA Contract NAw-6481. February 1957. 29p. diagrs., tabs. Metallurgical Research Labs., Syracuse U. Research Inst. MET415-572T. (Ask for N-61572*)

A major portion of the work has been devoted to the development of testing procedures for tension, compression, and fatigue tests at both room and elevated temperatures. Reliable test data for these extremely hard materials are very scarce. It is known that the results obtained on testing such alloys by conventional methods may be greatly affected by eccentricity, but apparently little attention has been paid to the critical evaluation and to the development of sufficiently accurate and consistent test procedures. The test data reported relate only to conventional melt 52100 steel.

Prepared for NACA on NACA Contract NAw-6481. August 1957. 103p. diagrs., photo., tabs. Metallurgical Research Labs., Syracuse U. Research Inst. Interim Tech. Rept. 2; MET415-5710T2. (Ask for N-61573*)

This report includes laboratory tests performed on 52100 electric furnace melt, 52100 vacuum melt, and Halmo vacuum melt steels at five different hardness levels; namely, 50, 54, 58, 62, and 65 Rc. The tension and compression elastic limits on these tests were obtained by the use of SR-4 gages and cycle loading. Also strain gages, an extensometer, and a dial indicator were used to obtain tensile and compressive strength data. For the performance of the tension and compression tests, special concentric fixtures were designed and built to keep the eccentricity factor as small as possible at room and elevated temperatures. Endurance limits at room temperature were obtained by the use of R. R. Moore type fatigue machines, adapted also for elevated temperature testing. In addition, Jominy hardenability tests were completed on two of the three materials.

NACA RM A50I27

FLIGHT-DETERMINED BUFFET BOUNDARIES OF TEN AIRPLANES AND COMPARISONS WITH FIVE BUFFETING CRITERIA. Burnett L. Gadeberg and Howard L. Ziff. January 5, 1951. 44p. diagrs., photo., tab. (NACA RM A50I27)

The flight-determined buffet boundaries of eight straight-wing and two swept-wing airplanes are presented. Comparisons are made with five proposed buffeting criteria. The general conformity of the trend of the buffet boundaries with that of the criteria for seven of the eight straight-wing airplanes indicates that the wing was probably the primary cause of the buffeting. A reasonable estimate of the buffet boundary of a straight-wing airplane may be obtained from the buffet criteria discussed.

NACA RM A52C04

EXPERIMENTAL INVESTIGATION OF THE STATIC AERODYNAMIC AND DYNAMIC DAMPING-IN-ROLL CHARACTERISTICS OF AN 8-CM AIRCRAFT ROCKET WITH SOLID AND SLOTTED FINS. Robert S. Chubb. June 1952. ii, 43p. diagrs., photo. (NACA RM A52C04)

The static aerodynamic and dynamic damping-in-roll characteristics of an 8-cm aircraft rocket having cruciform fins of trapezoidal plan form were determined experimentally at various Mach numbers ranging from 0.6 to 1.9. The effects of two large elongated slots cut through the panels of each stabilizing fin were investigated by testing both solid- and slotted-fin configurations.

NACA RM A53F12

CORRELATION BY THE HYPERSONIC SIMILARITY RULE OF PRESSURE DISTRIBUTIONS AND WAVE DRAGS FOR MINIMUM-DRAG NOSE SHAPES AT ZERO ANGLE OF ATTACK. Leland H. Jorgensen. August 1953. 23p. diagrs. (NACA RM A53F12)

Second-order-theory pressure distributions and wave drags for Kármán and Newtonian minimum-drag nose shapes (theoretically optimized for given length and diameter) are correlated for values of the hypersonic similarity parameter from about 0.4 to 1.0. From the correlated data simple expressions for pressure distribution and wave drag are developed. The theoretical wave-drag expressions for the Kármán and Newtonian shapes are checked with available experimental data, and drag comparisons are made with theoretical results for cones and tangent ogives.

NACA RM A53F22

LIFT, DRAG, AND HINGE MOMENTS AT SUPERSONIC SPEEDS OF AN ALL-MOVABLE TRIANGULAR WING AND BODY COMBINATION. William C. Drake. September 1953. 38p. diagrs., photos., tabs. (NACA RM A53F22)

Lift, drag, and hinge-moment variations with angles of attack and deflection are presented at a Mach number of 1.46; also presented are hinge-moment data at M = 1.99. Comparison of the results with the predictions of theory showed satisfactory agreement at small angles of attack and small deflections. It was found that variations of Reynolds number and wing-body gap, and fixing transition on the body nose had little or no effect within the scope of the tests.

NACA RM A54E12

A FLIGHT INVESTIGATION AT TRANSONIC SPEEDS OF THE AERODYNAMIC CHARACTERISTICS OF A MODEL HAVING A THIN UNSWEPT WING OF ASPECT RATIO 3.1. Maurice D. White. August 1954. 41p. diagrs., photo., tabs. (NACA RM A54E12)

The longitudinal aerodynamic characteristics of a model having a low-aspect-ratio, thin unswept wing and a 45° swept horizontal tail mounted in the chord plane of the wing were investigated at transonic speeds by the free-falling recoverable-model technique. Static and dynamic stability data, and some load-distribution results are presented.

NACA RM A55F02a

ADDITIONAL MEASUREMENTS OF THE LOW-SPEED STATIC STABILITY OF A CONFIGURATION EMPLOYING THREE TRIANGULAR WING PANELS AND A BODY OF EQUAL LENGTH. Noel K. Delany. July 1955. 31p. diagrs. (NACA RM A55F02a)

The model investigated had three triangular airfoils of low aspect ratio, two forming wings and one a vertical fin, radially disposed about a central body which had the same length as the airfoils. Two vertical-fin sizes were investigated as well as the effect of varying the dihedral from 0° to -30° for a large range of angles of attack and sideslip. The damping in roll for 0° angles of attack and sideslip was also measured.

NACA RM A55F06

ADDITIONAL COMPARISONS BETWEEN COMPUTED AND MEASURED TRANSONIC DRAG-RISE COEFFICIENTS AT ZERO LIFT FOR WING-BODY-TAIL CONFIGURATIONS. George H. Holdaway. August 1955. 43p. diagrs., photo., tabs. (NACA RM A55F06)

Zero-lift wave-drag coefficients computed by the method of NACA RM A53H17 for three triangular wings of aspect ratio 2, 3, and 4, and for an airfoil section modification on a 45° sweptback wing are shown to be in reasonable agreement with measured values.

NACA RM A55F21

A FLIGHT INVESTIGATION AT TRANSONIC SPEEDS OF A MODEL HAVING A TRIANGULAR WING OF ASPECT RATIO 2. Maurice D. White. September 1955. 39p. diagrs., photo., tabs. (NACA RM A55F21)

The longitudinal aerodynamic characteristics of a model having a triangular wing of aspect ratio 2 and a 45° sweptback horizontal tail located in the extended wing chord plane were investigated at transonic speeds by the free-falling recoverable-model technique. Static and dynamic longitudinal stability data, and force and moment data for the major components of the model are presented for Mach numbers from 0.8 to 1.1 and angles of attack up to about 25° to 30°, depending on the Mach number.

NACA RM A56F01

APPLICATION OF AREA SUCTION TO LEADING-EDGE AND TRAILING-EDGE FLAPS ON A 44° SWEPT-WING MODEL. Curt A. Holzhauser, Robert K. Martin, and V. Robert Page. September 1956. 66p. diagrs., photos., tabs. (NACA RM A56F01)

Lift, drag, and moment characteristics for a large-scale model with trailing-edge and leading-edge flaps were determined both with and without suction applied. Various chordwise extents of uniform and variable porosity were used in the tests and suction requirements are presented. Applying area suction to the trailing-edge flap increased the lift throughout the angle-of-attack range, and applying area suction to the leading-edge flap increased the maximum lift coefficient.

NACA RM E51F13

COMPARISON OF MEASURED EFFICIENCIES OF NINE TURBINE DESIGNS WITH EFFICIENCIES PREDICTED BY TWO EMPIRICAL METHODS. Robert E. English and Richard H. Cavicchi. August 1951. 23p. diagrs., tab. (NACA RM E51F13)

Empirical methods of Ainley and of Kochendorfer and Nettles were used to predict performances of nine turbine designs. Measured and predicted performances were compared. Appropriate values of blading-loss parameter were determined for the method of Kochendorfer and Nettles. The measured design-point efficiencies were lower than predicted by as much as 0.09 (Ainley) and 0.07 (Kochendorfer and Nettles). For the method of Kochendorfer and Nettles, appropriate values of blading-loss parameter ranged from 0.63 to 0.87 and the off-design performance was accurately predicted.

NACA RM E51F26

INVESTIGATION AT MACH NUMBER 1.91 OF SIDE AND BASE PRESSURE DISTRIBUTIONS OVER CONICAL BOATTAILS WITHOUT AND WITH JET FLOW ISSUING FROM BASE. Edgar M. Cortright, Jr., and Albert H. Schroeder. September 1951. 59p. diagrs., photos. (NACA RM E51F26)

Experimental side and base pressure distributions over a series of conical boattails without and with jet flow from the base are presented at a Mach number of 1.91. For the case of no jet flow, the methods of characteristics and linearized theory are shown to overpredict the side pressure drag. A semiempirical theory is presented to predict the effect of boattail angle on base pressure. With the boattail extending to a sharp edge at the nozzle exit, the overpressure jet is shown to decrease the side pressure drag. Presence of an annular base may eliminate the effect of the jet on the side pressure drag, but the jet effect on the base pressure drag may greatly increase or decrease the total boattail drag.

NACA RM E52B18

INVESTIGATION OF A 10-STAGE SUBSONIC AXIAL-FLOW RESEARCH COMPRESSOR. I - AERODYNAMIC DESIGN. Irving A. Johnsen. April 1952. 41p. diagrs., tabs. (NACA RM E52B18)

The aerodynamic design of a 10-stage axial-flow research compressor was based on the use of a symmetrical velocity diagram with constant total enthalpy at all radii. With the use of selected aerodynamic limitations, the design procedure established a design pressure ratio of 6.45 and an equivalent weight flow of 57.5 pounds per second at the design equivalent tip speed of 869 feet per second.

NACA RM E52C04

INVESTIGATION OF A 10-STAGE SUBSONIC AXIAL-FLOW RESEARCH COMPRESSOR. II - PRELIMINARY ANALYSIS OF OVER-ALL PERFORMANCE. Ray E. Budinger and Arthur R. Thomson. June 1952. 23p. diagrs., photos. (NACA RM E52C04)

An investigation of the overall performance of a 20-inch-tip-diameter 10-stage compressor was conducted as the initial step in an investigation of the problems encountered in an axial-flow compressor having a high pressure ratio per stage. The investigation was made over a range of weight flows at equivalent speeds from 30 to 110 percent of design speed. The compressor had a smooth surge line and a broad range of high part-speed efficiency. Maximum measured total-pressure ratio obtained at design speed was 7.52 at an equivalent weight flow of 53.7 pounds per second with an adiabatic efficiency of 0.81. Peak adiabatic efficiency of 0.84 was obtained at approximately 85 percent of design speed.

NACA RM E52F02

TRANSONIC FREE-FLIGHT INVESTIGATION OF THE TOTAL DRAG AND OF THE COMPONENT DRAGS (COWL PRESSURE, ADDITIVE, BASE, FRICTION, AND INTERNAL) ENCOUNTERED BY A 16-INCH-DIAMETER RAM-JET ENGINE FOR MACH NUMBERS FROM 0.80 TO 1.43. Wesley E. Messing and Leonard Rabb. August 1952. 34p. diagrs., photos. (NACA RM E52F02)

The transonic drag of a 16-inch-diameter ram-jet engine operating under simulated combustion conditions was determined for a Mach number range from 0.80 to 1.43. The components of the overall drag, namely, the additive, cowl pressure, friction, base, and internal drag, were determined for mass-flow ratios from 0.66 to 0.84. The total drag determined from the summation of the component drags agreed with the total drag as obtained from an independent measurement of the acceleration to within 94 percent.

NACA RM E52F25

SPREADING OF EXHAUST JET FROM 16-INCH RAM JET AT MACH NUMBER 2.0. Fred Wilcox and Donald Pennington. August 1952. 14p. diagrs., photo., tab. (NACA RM E52F25)

An investigation of the jet-spreading characteristics of a 16-inch ram-jet engine was conducted in the 8- by 6-foot supersonic tunnel at a Mach number of 2.0; both a converging nozzle having a contraction ratio of 0.71 and a cylindrical extension to the combustion chamber were used. The jet boundaries determined by means of pitot pressure surveys were compared with boundaries calculated from one-dimensional continuity and momentum relations. For the cylindrical nozzle, the jet reaches its maximum diameter, 4 percent greater than calculated, about 0.6 nozzle-exit diameter downstream of the nozzle exit. The maximum diameter for the converging nozzle was 7 percent greater than calculated from one-dimensional relations and occurred from 1 to 1.5 nozzle-exit diameters downstream of the exit. Non-dimensional maximum jet diameters agreed closely with results of an investigation by Rousso and Baughman; these data were obtained with low-temperature jets exhausting into a stream at a Mach number of 1.91 from nozzles having exit diameters of 0.75 inch.

NACA RM E53C11

INVESTIGATION OF A 10-STAGE SUBSONIC AXIAL-FLOW RESEARCH COMPRESSOR. IV - INDIVIDUAL STAGE PERFORMANCE CHARACTERISTICS. Ray E. Budinger and George K. Serovy. April 1953. 37p. diagrs., photo. (NACA RM E53C11)

The individual stage performance was determined for a 10-stage 20-inch tip diameter axial-flow compressor from circumferentially fixed radial rake measurements of total temperature and total pressure obtained at the discharge of each stage. The interstage data indicated that the knee in the compressor surge line and the shape of the intermediate speed curves appear to be directly associated with positive stall of some inlet stage at low speeds and its effect through stage interactions on the performance of succeeding and preceding stages. The magnitude of the knee in the surge line is probably affected by the type of stall initiated in the inlet stages. The progressive tip-to-hub stall found in the early stages of this compressor at low speeds lessens the effects of stage stall on the overall compressor performance and probably tends to reduce the effects of stage interactions.

NACA RM E53C19

INVESTIGATION OF A 10-STAGE SUBSONIC AXIAL-FLOW RESEARCH COMPRESSOR. III - INVESTIGATION OF ROTATING STALL, BLADE VIBRATION, AND SURGE AT LOW AND INTERMEDIATE COMPRESSOR SPEEDS. Merle C. Huppert, Eleanor L. Costilow, and Ray E. Budinger. May 1953. 47p. diagrs., photos., tabs. (NACA RM E53C19)

Rotating stall and surge were investigated at low and intermediate speeds on a 10-stage subsonic axial-flow research compressor. The flow fluctuations of rotating stall due to rotor tip stall of the inlet stages were obtained at compressor speeds up to and including 70 percent of design speed. The amplitude of the flow fluctuations due to rotating stall was greatest in the first four stages and somewhat reduced in the latter stages. Surge was found to result in cyclic stall and stall recovery of the compressor.

NACA RM E53F16

A COMPARISON OF SEVERAL SYSTEMS OF BOUNDARY-LAYER REMOVAL AHEAD OF A TYPICAL CONICAL EXTERNAL-COMPRESSION SIDE INLET AT MACH NUMBERS OF 1.88 AND 2.93. Thomas G. Piercy and Harry W. Johnson. September 1953. 58p. diagrs., photos. (NACA RM E53F16)

The performance of external-compression side inlet models using several systems of boundary-layer removal was determined at Mach numbers of 1.88 and 2.93. The investigation included conventional scoop-type removal and alternative systems of removal consisting of deflection wedges and cowl-lip scoops. It was observed that the maximum inlet total-pressure recoveries for all systems of boundary-layer removal were comparable when sufficient boundary layer was removed.

NACA RM E53F18

UTILIZATION OF EXTERNAL-COMPRESSION DIFFUSION PRINCIPLE IN DESIGN OF SHOCK-IN-ROTOR SUPERSONIC COMPRESSOR BLADING. John W. R. Creagh and John F. Klapproth. September 1953. 37p. diagrs., photos., tab. (NACA RM E53F18)

The application of the external-compression principle to a cascade of blades in an attempt to achieve a closer approach to isentropic contraction ratios in

DECLASSIFIED NACA RESEARCH REPORTS

supersonic compressor blading is presented. The limiting contraction ratio is shown to depend upon the entrance Mach number and the blade leading-edge wedge angle. Tests of a rotor designed to incorporate the external-compression principle gave no improvement over previous shock-in-rotor compressors. The observed contraction ratios were generally equal to or less than those observed in previous designs because of an inadequate allowance for the blade leading-edge thickness.

NACA RM E53H10

INVESTIGATION OF A 10-STAGE SUBSONIC AXIAL-FLOW RESEARCH COMPRESSOR. V - EFFECT OF REDUCING INLET-GUIDE-VANE TURNING ON OVER-ALL AND INLET-STAGE PERFORMANCE. Ray E. Budinger and George K. Serovy. March 1954. 37p. diagrs., photo. (NACA RM E53H10)

The inlet-guide-vane setting of a 10-stage compressor was reduced by 5° in order to approximate more closely the design absolute entrance flow angles to the first rotor. The performance of the inlet stage was obtained simultaneously with the overall compressor performance for both the original and the reset vanes in order to determine the effects of the radial redistribution of flow conditions entering the first rotor. At the reduced guide-vane setting only the speeds above the knee in the compressor surge line were noticeably affected. The surge pressure ratio and the choke weight flow increased from 7.52 to 7.66 and from 56.7 to 58.2 pounds per second, respectively, at design speed with approximately a one-point increase in peak efficiency. The knee in the compressor surge line occurred at 73 percent of design speed for the reduced guide-vane setting, compared with 70 percent for the original setting. The changes in overall compressor performance at high speeds were attributed primarily to the inlet stage, which exhibited a higher total-pressure ratio when operating at the same average angle of attack for the reduced guide-vane setting.

NACA RM E54B25

INVESTIGATION OF IMPULSE-TYPE SUPERSONIC COMPRESSOR WITH HUB-TIP RATIO OF 0.6 AND TURNING TO AXIAL DIRECTION. I - PERFORMANCE OF ROTOR ALONE. Ward W. Wilcox. May 1954. 41p. diagrs., photos., tab. (NACA RM E54B25)

The supersonic-compressor rotor described herein was designed as an impulse type with some deceleration along the tip and with turning to the axial direction. Design speed was 1400 feet per second, and the rotor was stressed to operate in air. Guide vanes were provided to set up a 16° counter prerotation at the tip with free-vortex-type distribution radially. Tests of the rotor and guide vanes determined that, at design speed, the maximum pressure ratio of 4.7 and peak efficiency of 0.85 occurred at the maximum weight flow of 24.84 pounds per second per square foot of frontal area. At this operating point, the average outlet Mach number was 1.75 and the average flow angle was 43.5°. At 90 percent speed, flow conditions were judged to be more satisfactory for stator work, inasmuch as the average Mach number dropped to 1.4 at a flow angle of 47°. At this point, the pressure ratio was 3.7, efficiency 0.86, and the weight flow 23.6 pounds per square foot unit frontal area. The radial distributions of pressure ratio, Mach number, and flow angle were considered satisfactory at this speed.

NACA RM E54F02

EXPERIMENTAL DATA FOR FOUR FULL-SCALE CONICAL COOLING-AIR EJECTORS. C. C. Ciepluch and D. B. Fenn. November 1954. 41p. diagrs., photo., tab. (NACA RM E54F02)

The ejector configurations investigated simulated a variable-primary-nozzle-area and variable-diameter-ratio ejector which operated at diameter ratios of 1.11 and 1.31 for nonafterburning and afterburning flight conditions, respectively. Performance data were obtained at spacing ratios of 0.4 and 0.8. The spacing ratio was found to influence both ejector pumping and thrust performance.

NACA RM E54F03

INVESTIGATION OF EFFECT OF INCREASED DIFFUSION OF ROTOR-BLADE SUCTION-SURFACE VELOCITY ON PERFORMANCE OF TRANSONIC TURBINE. Robert Y. Wong, Daniel E. Monroe, and William T. Wintucky. August 1954. 19p. diagrs., photo., tab. (NACA RM E54F03)

Design-point efficiency of a turbine with 0.30 diffusion parameter was four points less than that of a turbine with 0.15 diffusion. Surveys indicated comparable efficiencies in the hub and mean sections and a drop-off from the mean radius to the tip for both turbines that was much greater for the higher-diffusion turbine. The turbine three-dimensional characteristics may have an important effect on rotor losses by causing a transport of low-momentum fluids from the hub and mean section to the tip, which add to the measured losses and may even create further losses in this region.

NACA RM E54F21

AN EVALUATION OF TURBOJET ENGINE THRUST CONTROL BY EXHAUST-NOZZLE-AREA MODULATION AND COMPRESSOR-INLET THROTTLING. James L. Harp, Jr., Wallace W. Velie, and William E. Mallett. August 1954. 17p. diagrs., photos. (NACA RM E54F21)

At rated speed, a thrust reduction of 38 percent of rated thrust was obtained with an exhaust-nozzle area 45 percent greater than rated area. A thrust reduction of 61 percent of rated thrust was obtained by combined throttling of the engine inlet to produce a 31-percent pressure drop and use of the increased exhaust-nozzle area of 45 percent. Thrust reduction available from both exhaust-nozzle-area modulation and compressor-inlet throttling was predictable for this engine within an accuracy of 4 percent.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E54F23

INVESTIGATION OF TRANSONIC TURBINE DESIGNED FOR ZERO DIFFUSION OF SUCTION-SURFACE VELOCITY. Warren J. Whitney, Daniel E. Monroe, and Robert Y. Wong. August 1954. 20p. diagrs., photo., tab. (NACA RM E54F23)

From a comparison of the experimental performance of a zero-diffusion turbine with that of a 0.15- and a 0.30-diffusion turbine, the design-point efficiency of the subject turbine (between 0.86 and 0.87) represented an improvement in overall performance over that of the other turbines. From the results of the three turbines, it was indicated that the diffusion parameter is an important turbine design consideration that affects the overall turbine performance. As shown from previous compressor research, compressor blade losses could also be correlated by a similar diffusion factor.

NACA RM E54F28

INVESTIGATION OF A 10-STAGE SUBSONIC AXIAL-FLOW RESEARCH COMPRESSOR. VI - PERFORMANCE EVALUATION AND FLOW DISTRIBUTIONS IN THE FIRST, FIFTH, AND TENTH STAGES. Ray E. Budinger. August 1954. 42p. diagrs., photo., tabs. (NACA RM E54F28)

The results indicate that two-dimensional low-speed cascade data are applicable to subsonic compressor design. The stage efficiencies indicate lower peak values in the first and tenth stages than in the fifth stage, rather than the constant value assumed in the design. Simple radial equilibrium satisfactorily predicted the axial-velocity distributions in the first and fifth stages, but was inadequate in the tenth stage. Design matching of all three stages was not obtained at design speed because of high inlet-guide-vane turning. Higher than assumed design efficiencies and no boundary-layer allowance resulted in design matching of the fifth and tenth stages at design speed.

NACA RM E54G16

THERMAL STABILITY OF PENTABORANE IN THE RANGE 329° TO 419° F. Glen E. McDonald. December 1956. 4p. diagrs. (NACA RM E54G16)

The thermal stability of pentaborane, as measured by the formation of nonvolatile residue, has been determined as a function of time over the temperature range 329° to 419° F. A plot of the reciprocal Rankine temperature against the logarithm of the time in minutes required for the formation of 20-percent nonvolatile residue was linear. The time required for the formation of 20 percent of residue at either higher or lower temperatures may be estimated from extrapolation of this line.

NACA RM E55F28

INVESTIGATION OF IMPULSE-TYPE SUPERSONIC COMPRESSOR WITH HUB-TIP RATIO OF 0.6 AND TURNING TO AXIAL DIRECTION. II - STAGE PERFORMANCE WITH THREE DIFFERENT SETS OF STATORS. Ward W. Wilcox. August 1955. 49p. diagrs., photos., tab. (NACA RM E55F28)

An impulse-type supersonic compressor designed for turning to the axial direction was tested in air with three different sets of stator blades at eight angle settings. The good performance of the rotor alone was compromised by the stators. Low values of overall pressure ratio and adiabatic efficiency were observed, and range of weight flow was severely restricted. At stator-inlet Mach numbers below 1.4, most of the losses occurred as a result of secondary flows, friction, and mixing of the nonuniform Mach number and energy levels that came from the rotor.

NACA RM E55F29a

SPONTANEOUS IGNITION OF PENTABORANE SPRAYS IN A HOT-AIR STREAM. Erwin A. Lezberg and Albert M. Lord. November 1956. 26p. diagrs. (NACA RM E55F29a)

The boron hydrides, because of their high reactivity, have been suggested for use as ignition or relight fuels in jet engines. Spontaneous-ignition temperatures and ignition delays were therefore determined for pentaborane in a hot-air stream. Ignition temperatures from 600° to 675° F were found for ignition delays of about 3 to 20 milliseconds over a range of pressure from 5 to 29 in. Hg abs. Temperature effects on ignition delay can be represented by the Arrhennius equation, and pressure effects by an equation of the type $p^n = ke^{-E/RT}$. The mean value of n was 1.6 for combustor pressures of 10 to 29 in. Hg abs. A flame stabilizer reduced ignition temperatures for pentaborane.

NACA RM E55F30

A VARIABLE-GEOMETRY AXISYMMETRIC SUPERSONIC INLET WITH TELESCOPING CENTERBODY. James F. Connors and Rudolph C. Meyer. September 1955. 27p. diagrs., photos., tabs. (NACA RM E55F30)

A centerbody consisting of a number of individual, translating, concentric elements was used to produce a discontinuous surface, the envelope of which approximated any desired contour. In an actual inlet application, maximum total-pressure recoveries of 0.89 and 0.60 were obtained at Mach numbers of 1.90 and 3.05, respectively. At both Mach numbers, supercritical mass-flow ratios of approximately unity were obtained with subcritical stability ranges of 38 and 21 percent of maximum possible mass flow.

NACA RM E55H02

FACTORS THAT AFFECT OPERATIONAL RELIABILITY OF TURBOJET ENGINES. Lewis Laboratory Staff. January 1956. 376p. diagrs., photos., tabs. (NACA RM E55H02)

The problem of improving operational reliability of turbojet engines is studied in a series of papers. Failure statistics for this engine are presented, the theory and experimental evidence on how engine failures occur are described, and the methods available for avoiding failure in operation are discussed. The individual papers of the series are Objectives, Failure Statistics, Foreign-Object Damage, Compressor Blades, Combustor Assembly, Nozzle Diaphragms, Turbine Buckets, Turbine Disks, Rolling Contact Bearings, Engine Fuel Controls, and Summary Discussion.

NACA RM E56F11a

EFFECTS OF EXTERNAL STREAM FLOW AND AFTERBODY VARIATIONS ON THE PERFORMANCE OF A PLUG NOZZLE AT HIGH SUBSONIC SPEEDS. R. J. Salmi and E. M. Cortright, Jr. October 1956. 19p. diagrs. (NACA RM E56F11a)

The off-design operation of an isentropic plug nozzle designed for a jet pressure ratio of 15 was investigated experimentally at subsonic Mach numbers up to 0.9 and jet pressure ratios up to 5. When installed in a cylindrical nacelle with a sharp turn at the nozzle lip, the interaction of the jet and the external stream produced low pressures on the base formed by the high lip angle. These low pressures increased the nacelle drag and caused an overexpansion of the jet, which resulted in lower pressures on the plug and, hence, reduced thrust. With a boattail ahead of the plug nozzle, the base pressures were increased and the jet overexpansion significantly reduced.

NACA RM E56F21

ANALYSIS OF TURBOMACHINE VISCOUS LOSSES AFFECTED BY CHANGES IN BLADE GEOMETRY. James W. Miser, Warner L. Stewart, and Warren J. Whitney. October 1956. 50p. diagrs., tab. (NACA RM E56F21)

The effect of changes in blade geometry on the viscous losses in turbomachines is analyzed. The viscous losses can be expressed as a function of three variables: the blade height-to-spacing ratio, the solidity, and a blade-height Reynolds number. A method of optimizing the number of blades and the solidity is given. The effect of trailing-edge blockage on blade loss and its effect on the choice of blade number for a particular design are also discussed.

NACA RM E56F29

ANALYSIS OF TURBOJET-ENGINE CONTROLS FOR AFTERBURNER STARTING. W. E. Phillips, Jr. October 1956. 61p. diagrs., tabs. (NACA RM E56F29)

A simulation procedure is developed for studying the effects of an afterburner start on a controlled turbojet engine. The afterburner start is represented by introducing a step decrease in the effective exhaust-nozzle area, after which the control returns the controlled engine variables to their initial values. The degree and speed with which the control acts are a measure of the effectiveness of the particular control system. Data are presented from five systems investigated using an electronic analog computer and the developed simulation procedure. These systems are compared with respect to steady-state errors, speed of response, and transient deviations of the system variables.

NACA RM E57A28

ANALYSIS OF EXPERIMENTAL LOW-SPEED LOSS AND STALL CHARACTERISTICS OF TWO-DIMENSIONAL COMPRESSOR BLADE CASCADES. Seymour Lieblein. March 1957. 64p. diagrs., tabs. (NACA RM E57A28)

Significant experimental correlation between pressure loss and blade loading is obtained for several conventional 10-percent-thick low-speed compressor cascade blades when loss is expressed in terms of ratio of wake momentum thickness to chord length and blade loading is expressed as the diffusion ratio given either by the measured ratio of maximum blade upper-surface velocity to outlet velocity or an equivalent ratio based on the velocity triangle and the blade solidity. Limiting diffusion ratios are established for stall at minimum loss and higher angles of attack, and procedures for estimating low-speed total-pressure loss and unstalled range of operation are presented.

NACA RM H54G29a

DETERMINATION OF LONGITUDINAL HANDLING QUALITIES OF THE D-558-II RESEARCH AIRPLANE AT TRANSONIC AND SUPERSONIC SPEEDS TO A MACH NUMBER OF ABOUT 2.0. Herman O. Ankenbruck. November 1954. 25p. diagrs., photos., tab. (NACA RM H54G29a)

Flight tests were performed with the Douglas D-558-II research airplane to investigate the longitudinal handling qualities and trim characteristics at transonic and supersonic speeds. This paper describes the changes with Mach number of the lift, maneuvering, and trim characteristics with elevator and stabilizer to a Mach number of about 2.0.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM H54H16

LONGITUDINAL STABILITY CHARACTERISTICS IN ACCELERATED MANEUVERS AT SUBSONIC AND TRANSONIC SPEEDS OF THE DOUGLAS D-558-II RESEARCH AIRPLANE EQUIPPED WITH A LEADING-EDGE WING CHORD-EXTENSION. Jack Fischel and Cyril D. Brunn. October 1954. 62p. diagrs., photos., tab. (NACA RM H54H16)

On the basis of improved longitudinal stability characteristics exhibited in wind-tunnel model tests, the Douglas D-558-II research airplane was modified to include wing leading-edge chord-extensions, and was flight tested at Mach numbers up to about 1.0. The results of subsonic and transonic flight measurements of the longitudinal stability characteristics of the airplane are presented. The levels of normal-force coefficient at which the stick-fixed stability decays and pitch-up starts have been determined through the speed range tested, as have the variation of the stability parameters $d\delta_e/dC_{N_A}$, dF_e/dn, and $dC_{N_A}/d\alpha$ with Mach number. Comparisons of these data with comparable data for the unmodified airplane are also presented.

NACA RM H54I27

LATERAL MOTIONS ENCOUNTERED WITH THE DOUGLAS D-558-II ALL-ROCKET RESEARCH AIRPLANE DURING EXPLORATORY FLIGHTS TO A MACH NUMBER OF 2.0. Herman O. Ankenbruck and Chester H. Wolowicz. December 1954. 32p. diagrs., photos., tab. (NACA RM H54I27)

Flight tests were performed with the Douglas D-558-II research airplane to investigate the lateral motions obtained during exploratory flights at supersonic speeds. This paper describes the effects of Mach number and angle of attack on the lateral handling qualities during oscillations at supersonic speeds. Some calculations of period and damping are included. Also shown are the results of some measurements of the variation of rudder hinge moments with sideslip and the effects of power on the variation.

NACA RM H54L27

WING-LOAD MEASUREMENTS AT SUPERSONIC SPEEDS OF THE DOUGLAS D-558-II RESEARCH AIRPLANE. Glenn H. Robinson, George E. Cothren, Jr., and Chris Pembo. March 1955. 20p. diagrs., photos., tab. (NACA RM H54L27)

Flight measurements of the aerodynamic wing loads on the D-558-II airplane have been made in the Mach number range from 1.0 to 2.0. Results of measurements of the wing-panel normal-force, bending-moment, and pitching-moment coefficients, normal-force-curve slope, lateral center of pressure, and chordwise center of pressure are presented.

NACA RM H55E31a

EFFECT OF SEVERAL WING MODIFICATIONS ON THE LOW-SPEED STALLING CHARACTERISTICS OF THE DOUGLAS D-558-II RESEARCH AIRPLANE. Jack Fischel and Donald Reisert. July 1955. 62p. diagrs., photos., tabs. (NACA RM H55E31a)

The low-speed stalling and lift characteristics of the Douglas D-558-II research airplane were measured in a series of 1g stalls performed with several wing modifications designed to alleviate swept-wing instability and pitch-up. The various configurations investigated include the basic wing configuration and two wing-fence configurations in combination with retracted, free-floating, or extended slats, and a wing leading-edge chord-extension configuration. All configurations were investigated with flaps and landing gear retracted and extended.

NACA RM H55J18

MACH NUMBER MEASUREMENTS AND CALIBRATIONS DURING FLIGHT AT HIGH SPEEDS AND AT HIGH ALTITUDES INCLUDING DATA FOR THE D-558-II RESEARCH AIRPLANE. Cyril D. Brunn and Wendell H. Stillwell. March 1956. 31p. diagrs., tabs. (NACA RM H55J18)

This paper contains data concerning research equipment and techniques pertaining to measurements of airspeed and altitude, with particular reference to high Mach number and altitude. Computations are presented for errors in determining Mach number for altitudes of 40,000 feet to 140,000 feet. Illustrative examples are included for maximum Mach number and altitude flights of the Douglas D-558-II research airplane.

NACA RM H56C30

EFFECT OF SEVERAL WING MODIFICATIONS ON THE SUBSONIC AND TRANSONIC LONGITUDINAL HANDLING QUALITIES OF THE DOUGLAS D-558-II RESEARCH AIRPLANE. Jack Fischel and Donald Reisert. June 1956. 57p. diagrs., photos., tabs. (NACA RM H56C30)

The subsonic and transonic longitudinal handling qualities of the Douglas D-558-II research airplane were measured with several wing modifications designed to alleviate swept-wing instability and pitch-up. Airplane configurations investigated include the basic wing configuration and two wing-fence configurations in combination with retracted, free-floating, or extended slats, and a wing leading-edge chord-extension configuration. Results indicated that the comparative effects of these wing modifications on airplane pitch-up and trim-stability and on the stability parameters $\frac{d\delta_e}{dC_N}$, $\frac{dF_e}{da_n}$, and C_{N_α} were essentially negligible. The various modifications had some measurable effect on airplane buffeting characteristics.

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A 42.8° SWEPTBACK CIRCULAR-ARC WING WITH ASPECT RATIO 4.00, TAPER RATIO 0.50, AND SWEPTBACK TAIL SURFACES. Joseph Weil, Paul Comisarow, and Kenneth W. Goodson. October 17, 1947. 84p. diagrs., photos., tab. (NACA RM L7G28)

Tests were made in the Langley 300-mph 7- by 10-foot tunnel of an airplane model to determine its low-speed longitudinal stability and control characteristics. This investigation includes data on the effect of vertical-wing location, fuselage size, horizontal-tail location, stall-control vanes on the wing, and nose-flap deflection.

NACA RM L7G31

LATERAL STABILITY AND CONTROL CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A 42.8° SWEPTBACK CIRCULAR-ARC WING WITH ASPECT RATIO 4.00, TAPER RATIO 0.50, AND SWEPTBACK TAIL SURFACES. Kenneth W. Goodson and Paul Comisarow. October 17, 1947. 72p. diagrs., photos., tab. (NACA RM L7G31)

Low-speed lateral stability and control data are given for a model of a proposed supersonic airplane having a swept circular-arc wing. A series of changes including lowering the wing, incorporating a smaller-fineness-ratio fuselage, and increasing the vertical-tail size were made to improve the aerodynamic characteristics of the original-model configuration.

NACA RM L7J15

SUPERSONIC-TUNNEL TESTS OF TWO SUPERSONIC AIRPLANE MODEL CONFIGURATIONS. Macon C. Ellis, Jr., Lowell E. Hasel, and Carl E. Grigsby. December 31, 1947. 49p. diagrs., photos., tab. (NACA RM L7J15)

Supersonic-tunnel tests of two supersonic airplane model configurations were made at Mach numbers of 1.55, 1.90, and 2.32 to determine values of the lift, drag, pitching moment, yawing moment, and side force. The principal difference between the two models was the vertical location of the wing relative to the horizontal tail. The test results indicated no difference in the lift characteristics and little difference in the drag characteristics of the two models. However, a significant variation with Mach number of the differences between the pitching-moment values is shown by the test results.

NACA RM L8D02

PRELIMINARY INVESTIGATION AT A MACH NUMBER OF 1.9 AND A REYNOLDS NUMBER OF 2,200,000 OF THREE AILERONS APPLICABLE TO THE BELL XS-2 AIRPLANE DESIGN. James C. Sivells and D. William Conner. May 25, 1948. 11p. diagrs., tab. (NACA RM L8D02)

A 42.7° sweptback tapered wing with three types of ailerons was tested at a Mach number of 1.9 and a Reynolds number of 2,200,000 in the Langley 9- by 12-inch supersonic blowdown tunnel. The wing geometry was essentially that of the XS-2 airplane.

NACA RM L8I14

WIND-TUNNEL INVESTIGATION OF THE STABILITY OF THE JETTISONABLE NOSE SECTION OF THE XS-2 AIRPLANE. Stanley H. Scher and Roscoe H. Goodwin. October 14, 1948. 19p. diagrs., photos., tabs. (NACA RM L8I14)

An investigation of the stability of the jettisonable nose section of the XS-2 airplane has been conducted in the Langley 20-foot free-spinning tunnel. It was found that the model rotated end over end about its normal axis or rolled about its longitudinal axis. Installation of suitable fins caused the model to descend in a stable nose-down attitude.

NACA RM L9G13

ANALYSIS OF THE DYNAMIC-LATERAL-STABILITY CHARACTERISTICS OF THE BELL X-2 AIRPLANE AS AFFECTED BY VARIATIONS IN MASS, AERODYNAMIC, AND DIMENSIONAL PARAMETERS. W. H. Michael, Jr., and M. J. Queijo. August 10, 1949. 33p. diagrs., tabs. (NACA RM L9G13)

Contains results of calculations to show the effects of various mass and aerodynamic parameters on the dynamic lateral stability of the Bell X-2 airplane in

DECLASSIFIED NACA RESEARCH REPORTS

the landing configuration and in the high-speed configuration at Mach numbers below 0.87. Calculations included determination of the period and rate of damping of the lateral oscillation, and the results are compared with the USAF criterion for satisfactory period-damping relationship.

NACA RM L9G15a

AN INVESTIGATION IN THE LANGLEY 20-FOOT FREE-SPINNING TUNNEL OF THE SPIN AND RECOVERY CHARACTERISTICS OF A 1/30-SCALE MODEL OF THE BELL X-2 AIRPLANE. Lawrence J. Gale. July 20, 1949. 15p. diagrs., photo., tabs. (NACA RM L9G15a)

An investigation of the spin and recovery characteristics of a 1/30-scale model of the Bell X-2 airplane has been conducted in the Langley 20-foot free-spinning tunnel. The effects of control settings upon the erect- and inverted-spin and recovery characteristics of the model were determined for the model at the design gross-weight loading condition. The effects of varying the loading, the stabilizer incidence, and of extending the leading-edge and trailing-edge wing flaps were also determined.

NACA RM L9L08

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. STATIC LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS AT A MACH NUMBER OF 1.40. M. Leroy Spearman. April 3, 1950. 27p. diagrs., photos., tab. (NACA RM L9L08)

Tests were made in the Langley 4- by 4-foot supersonic tunnel to determine the longitudinal stability and control characteristics at a Mach number of 1.40 of an airplane model having a 40° sweptback circular-arc wing with aspect ratio 4 and taper ratio 0.5. The tests covered an angle-of-attack range from -4° to 10° for the model with the stabilizer removed and with the stabilizer on with incidence angles from 3.7° to -10.2°.

NACA RM L50C17

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. STATIC LATERAL STABILITY CHARACTERISTICS AT MACH NUMBERS OF 1.40 AND 1.59. M. Leroy Spearman. June 14, 1950. 28p. diagrs., photos., tab. (NACA RM L50C17)

Tests were made in the Langley 4- by 4-foot supersonic tunnel to determine the lateral stability characteristics of a supersonic airplane configuration at Mach numbers of 1.40 and 1.59. A comparison is made with results of tests in the Langley 9-inch supersonic tunnel of a similar model.

NACA RM L50C24

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. A PRESSURE-DISTRIBUTION STUDY OF THE AERODYNAMIC CHARACTERISTICS OF THE WING AT MACH NUMBER 1.59. Morton Cooper and M. Leroy Spearman. May 23, 1950. 52p. diagrs., photos., tabs. (NACA RM L50C24)

A pressure-distribution investigation on a tapered 40° swept wing of aspect ratio 4 and of circular-arc sections has been conducted in the Langley 4- by 4-foot supersonic tunnel at a Mach number of 1.59 and a Reynolds number of 0.575×10^6. A comparison of the results of the experimental measurements is made with linear supersonic theory to indicate the accuracy with which the flow can be estimated.

NACA RM L50E08

SUPPLEMENTARY ANALYSIS OF THE DYNAMIC LATERAL STABILITY CHARACTERISTICS OF THE BELL X-2 AIRPLANE AS AFFECTED BY VARIATIONS IN MASS AND AERODYNAMIC PARAMETERS. William H. Michael, Jr., and M. J. Queijo. June 26, 1950. 15p. diagrs. (NACA RM L50E08)

Contains results of extended calculations of the dynamic lateral stability of the Bell X-2 airplane utilizing values of the derivative of yawing moment due to rolling C_{n_p} based on results of recent research.

NACA RM L50E12

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. STATIC LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS AT A MACH NUMBER OF 1.59. M. Leroy Spearman and John H. Hilton, Jr. June 29, 1950. 22p. diagrs., photo., tab. (NACA RM L50E12)

An investigation has been conducted to determine the static longitudinal stability and control characteristics at Mach number 1.59 of an airplane model having a 40° sweptback, circular-arc wing with aspect ratio 4 and taper ratio 0.5. The tests covered an angle-of-attack range from -4° to 10° with the stabilizer removed and with the stabilizer on with incidence angles from 4° to -10°. A comparison is made with results obtained for the same model at a Mach number of 1.40.

NACA RM L50H16

FLIGHT MEASUREMENTS WITH THE DOUGLAS D-558-II (BUAERO NO. 37974) RESEARCH AIRPLANE. MEASUREMENTS OF WING LOADS AT MACH NUMBERS UP TO 0.87. John P. Mayer, George M. Valentine, and Beverly J. Swanson. December 26, 1950. 35p. diagrs., photos., tab. (NACA RM L50H16)

Results are presented from flight measurements of the aerodynamic wing normal force, bending moment, and pitching moment on the Douglas D-558-II airplane at Mach numbers up to 0.87 and at angles of attack up to 38° for low Mach numbers.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L50I11

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. STATIC LATERAL CONTROL CHARACTERISTICS AT MACH NUMBERS OF 1.40 AND 1.59. Ross B. Robinson. November 10, 1950. 40p. diagrs., photos., tabs. (NACA RM L50I11)

An investigation was conducted in the Langley 4- by 4-foot supersonic tunnel to determine the lateral control characteristics of a supersonic aircraft configuration at Mach numbers of 1.40 and 1.59. Aileron tests were made through an angle-of-attack range of -4° to 10° at zero angle of yaw with an aileron-deflection range of about ±15°. Rudder tests were made through a yaw range of ±10° at zero angle of attack with a rudder-deflection range of -3° to 20° for $M = 1.40$ and -3° to 25.5° for $M = 1.59$. A discussion of the accuracy of the strain-gage balance system used is included.

NACA RM L50J13

FLIGHT MEASUREMENTS WITH THE DOUGLAS D-558-II (BUAERO NO. 37974) RESEARCH AIRPLANE. MEASUREMENTS OF THE DISTRIBUTION OF THE AERODYNAMIC LOAD AMONG THE WING, FUSELAGE, AND HORIZONTAL TAIL AT MACH NUMBERS UP TO 0.87. John P. Mayer and George M. Valentine. January 19, 1951. 33p. diagrs., photos., tab. (NACA RM L50J13)

Flight measurements of aerodynamic wing and tail loads have been made on the Douglas D-558-II airplane from which the distribution of the aerodynamic load among the wing, fuselage, and horizontal tail has been determined at Mach numbers up to 0.87.

NACA RM L50J31

AN INVESTIGATION AT MACH NUMBERS OF 1.40 AND 1.59 OF THE EFFECTS OF AILERON PROFILE ON THE AERODYNAMIC CHARACTERISTICS OF A COMPLETE MODEL OF A SUPERSONIC AIRCRAFT CONFIGURATION. M. Leroy Spearman and Robert A. Webster. January 15, 1951. 40p. diagrs., photos., tabs. (NACA RM L50J31)

Tests were made in the Langley 4- by 4-foot supersonic tunnel at Mach numbers of 1.40 and 1.59 to determine the effects of aileron profile on the aerodynamic characteristics of a complete model having a tapered wing with circular-arc sections and 40° sweepback. The profiles included the basic circular-arc section and three flat-sided ailerons having ratios of trailing-edge thickness to hinge-line thickness of 0, 0.5, and 1.0. The tests covered an angle-of-attack range of -4° to 10° with an aileron-deflection range of about ±15°.

NACA RM L50K14

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. FORCE CHARACTERISTICS OF THE COMPLETE CONFIGURATION AND ITS VARIOUS COMPONENTS AT MACH NUMBERS OF 1.40 AND 1.59. Norman F. Smith and Jack E. Marte. January 22, 1951. 55p. diagrs., photos., tab. (NACA RM L50K14)

A force investigation of a supersonic aircraft configuration and various combinations of its components has been conducted in the Langley 4- by 4-foot supersonic tunnel at Mach numbers of 1.40 and 1.59 and a Reynolds number of 0.6×10^6. The wing of the model had a sweepback of 40°, aspect ratio of 4, and 10-percent-thick circular-arc sections. Longitudinal- and lateral-force characteristics and stability derivatives are presented, along with interference effects. Comparisons with theory and with results of pressure investigations are made.

#NACA RM L50K24, by NACA Pilotless Aircraft Research Division.

NACA RM L51C06

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTION AND 40° SWEEPBACK. A PRESSURE-DISTRIBUTION STUDY OF THE AERODYNAMIC CHARACTERISTICS OF THE WING AT MACH NUMBER 1.40. Norman F. Smith, Julian H. Kainer, and Robert A. Webster. April 20, 1951. 48p. diagrs., photos., tabs. (NACA RM L51C06)

A pressure-distribution investigation of a wing having 10-percent-thick circular-arc sections perpendicular to the quarter-chord line, 40° sweepback of the quarter-chord line, a taper ratio of 0.5, and an aspect ratio of 4 was conducted in the Langley 4- by 4-foot supersonic tunnel at a Mach number of 1.40 and a Reynolds number, based on the mean aerodynamic chord, of 0.598×10^6. Comparisons of the results of the experimental measurements at Mach number 1.40 are made with linearized supersonic theory and with previously published data for Mach number 1.59.

NACA RM L51E14

AN INVESTIGATION OF SINGLE-DEGREE-OF-FREEDOM SNAKING OSCILLATIONS ON A MODEL OF A HIGH-SPEED RESEARCH AIRPLANE BY THE NACA WING-FLOW METHOD. Harold I. Johnson and Stanley Faber. August 1951. 22p. diagrs., photos., tab. (NACA RM L51E14)

Records are presented showing the snaking characteristics of 12 different configurations of a 1/40-scale wingless model of a research airplane and of another higher fineness-ratio model. The models were mounted on a wing-flow test panel with freedom to rotate in yaw only. The test Mach number range was 0.70 to 1.15. Results indicated snaking can be caused by flow separation. In the subject investigation the snaking was largely eliminated by making the rates of closure of the aerodynamic bodies and surfaces small.

NACA RM L51F05

BASIC PRESSURE MEASUREMENTS ON A FUSELAGE AND A 45° SWEPTBACK WING-FUSELAGE COMBINATION AT TRANSONIC SPEEDS IN THE

UNAVAILABLE; contains proprietary or obsolete information.

DECLASSIFIED NACA RESEARCH REPORTS

SLOTTED TEST SECTION OF THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Donald L. Loving and Claude V. Williams. September 1951. 59p. diagrs., photos. (NACA RM L51F05)

A discussion is presented on the basic pressure measurements made on a fuselage and a wing-fuselage combination employing a wing having 45° of sweepback of the 0.25-chord line, aspect ratio 4, taper ratio 0.6, and NACA 65A006 airfoil sections parallel to the airstream. The pressure data were obtained at Mach numbers from 0.60 to 1.13 and angles of attack from 0° to 20° in the slotted test section of the Langley 8-foot high-speed tunnel.

NACA RM L51L17

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. ESTIMATED DOWNWASH ANGLES DERIVED FROM PRESSURE MEASUREMENTS ON THE TAIL AT MACH NUMBERS OF 1.40 AND 1.59. Frederick C. Grant and John P. Gapcynski. March 1952. 27p. diagrs., photos., tabs. (NACA RM L51L17)

A comparison is made between estimated downwash values obtained from an analysis of pressures on the horizontal tail of a supersonic aircraft configuration with a 40° sweptback wing and those obtained from an application of linearized theory. This is done for Mach numbers 1.40 and 1.59 with the wing on and the wing off. Available force-tests results are compared with pressure and theoretical results.

NACA RM L52A08

HANDLING QUALITIES OF HIGH-SPEED AIRPLANES. W. C. Williams and A. S. Crossfield. January 1952. 17p. diagrs. (NACA RM L52A08)

Because there have been such drastic changes in the speed range and the configuration of airplanes in the past decade it becomes necessary to reexamine the requirements for satisfactory handling qualities as proposed by Gilruth in 1940. This paper does not attempt to describe completely the handling qualities of all the research airplanes but does attempt to describe the objectionable characteristics and those which indicate review of the requirements. The research airplanes discussed are the X-1, D-558-1, D-558-2, X-4, F-86A, and the XF-92A.

NACA RM L52A21

THE AERODYNAMIC CHARACTERISTICS OF A SUPERSONIC AIRCRAFT CONFIGURATION WITH A 40° SWEPTBACK WING THROUGH A MACH NUMBER RANGE FROM 0 TO 2.4 AS OBTAINED FROM VARIOUS SOURCES. M. Leroy Spearman and Ross B. Robinson. April 1952. 50p. diagrs., photo., tab. (NACA RM L52A21)

A summary and analysis have been made of the results of various investigations to determine the aerodynamic characteristics of a supersonic aircraft configuration. This configuration had a wing with 40° sweepback at the quarter-chord line, aspect ratio 4, taper ratio 0.5, and 10-percent-thick circular-arc sections normal to the quarter-chord line. Experimental data were available for a Mach number range from 0.16 to 2.32. Results obtained from wing-flow, rocket-model, transonic-bump, and tunnel tests are presented and, where possible, are supplemented by empirical and theoretical calculations.

NACA RM L52F13

EFFECTS OF SYSTEMATICALLY VARYING THE SPANWISE AND VERTICAL LOCATION OF AN EXTERNAL STORE ON THE AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT TAPERED WING OF ASPECT RATIO 4 AT MACH NUMBERS OF 1.41, 1.62, AND 1.96. Carl R. Jacobsen. August 1952. 34p. diagrs. (NACA RM L52F13)

An investigation has been made in the Langley 9- by 12-inch supersonic blowdown tunnel to determine the effects of an external store on the lift, drag, and pitching-moment characteristics of an unswept wing at Mach numbers of 1.41, 1.62, and 1.96. The spanwise and vertical location of a store having the Douglas Aircraft Company store shape was systematically varied over the outer 60 percent of the wing semispan. For a wing area of 500 square feet, the store would have sufficient volume to contain about 400 gallons of fuel.

NACA RM L52I18

LOW-SPEED STATIC LONGITUDINAL AND LATERAL STABILITY CHARACTERISTICS OF A MODEL WITH LEADING-EDGE CHORD-EXTENSIONS INCORPORATED ON A 40° SWEPTBACK CIRCULAR-ARC WING OF ASPECT RATIO 4 AND TAPER RATIO 0.50. Kenneth W. Goodson and Albert G. Few, Jr. November 1952. 46p. diagrs., photos., tab. (NACA RM L52I18)

An investigation was conducted to determine the aerodynamic effects at low speed of wing leading-edge chord-extensions incorporated on a complete airplane model having a 40° sweptback circular-arc wing of aspect ratio 4 and taper ratio 0.5. Comparison of several nose and plain-flap configurations in conjunction with a chord-extension are also made.

NACA RM L52I26a

MEASUREMENTS OF AERODYNAMIC HEATING OBTAINED DURING DEMONSTRATION FLIGHT TESTS OF THE DOUGLAS D-558-II AIRPLANE. Ira P. Jones, Jr. November 1952. 19p. diagrs., photo., tab. (NACA RM L52I26a)

Measurements of transient skin and canopy-glass temperature and stagnation temperature were made on the Douglas D-558-II research airplane up to a Mach number of 1.89 and to an altitude of about 77,000 feet. The maximum temperatures that were obtained for the positions measured were not great enough to cause loss in structural strength.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L52L02a

SOME EFFECTS OF A SONIC JET EXHAUST ON THE LOADING OVER A YAWED FIN AT A MACH NUMBER OF 3.03. John E. Hatch, Jr., and William M. Savelle. January 1953. 12p. diagrs., photo. (NACA RM L52L02a)

The results of an experimental investigation are presented which show the effects of a sonic jet exhaust on the loading over a yawed fin located at the jet exit in a free stream of Mach number 3.03.

NACA RM L53A06

SOME MEASUREMENTS OF FLYING QUALITIES OF A DOUGLAS D-558-II RESEARCH AIRPLANE DURING FLIGHTS TO SUPERSONIC SPEEDS. Herman O. Ankenbruck and Theodore E. Dahlen. March 1953. 25p. diagrs., photos., tab. (NACA RM L53A06)

Results of measurements of lateral and longitudinal flying qualities of the Douglas D-558-II research airplane in flights to a Mach number of 1.87 and an altitude of 67,000 feet are presented.

NACA RM L53A16

FLIGHT DETERMINATION OF THE LONGITUDINAL STABILITY IN ACCELERATED MANEUVERS AT TRANSONIC SPEEDS FOR THE DOUGLAS D-558-II RESEARCH AIRPLANE INCLUDING THE EFFECTS OF AN OUTBOARD WING FENCE. Jack Fischel and Jack Nugent. March 1953. 28p. diagrs., photo., tab. (NACA RM L53A16)

The results of transonic flight measurements of the longitudinal stability characteristics of the Douglas D-558-II research airplane in the original configuration and with outboard fences mounted on the wings are presented. The levels of normal-force coefficient at which the stability decreases and pitch-up starts have been determined for both airplane configurations at Mach numbers up to about 0.94.

NACA RM L53B24

MAXIMUM ALTITUDE AND MAXIMUM MACH NUMBER OBTAINED WITH THE MODIFIED DOUGLAS D-558-II RESEARCH AIRPLANE DURING DEMONSTRATION FLIGHTS. Theodore E. Dahlen. April 1953. 14p. diagrs., tabs. (NACA RM L53B24)

The maximum values of Mach number and altitude obtained with the Douglas D-558-II all-rocket research airplane and determined by the radar-phototheodolite method are presented in this paper.

NACA RM L53C06

FREE-SPINNING-TUNNEL INVESTIGATION TO DETERMINE THE EFFECT OF SPINS AND RECOVERIES OF WING LEADING-EDGE CHORD-EXTENSIONS AND DROOPED LEADING-EDGE FLAPS ON SCALE MODELS OF TWO SWEPTBACK-WING FIGHTER AIRPLANES. Jack H. Wilson and Walter J. Klinar. May 1953. 28p. photo., diagrs., tabs. (NACA RM L53C06)

An investigation was conducted in the Langley 20-foot free-spinning tunnel to determine the effect of wing chord-extensions and drooped leading-edge flaps on the spin and recovery characteristics of models of two swept-wing fighter airplanes. A comparison of the spin and recovery characteristics of each model with and without chord-extensions installed in the chord plane of the wing is presented. Results are also presented for one model with drooped chord-extensions in conjunction with drooped leading-edge flaps.

NACA RM L53D06

SOME MEASUREMENTS OF THE BUFFET REGION OF A SWEPT-WING RESEARCH AIRPLANE DURING FLIGHTS TO SUPERSONIC MACH NUMBERS. Thomas F. Baker. May 1953. 14p. diagrs., photos., tab. (NACA RM L53D06)

Limited measurements have been made of the region in which buffeting has been experienced by the swept-wing Douglas D-558-II research airplane during flights to supersonic Mach numbers. Buffet intensities and frequencies are given.

NACA RM L53E21

ENGINEERING METHOD OF RAM-JET THRUST DETERMINATION BASED ON EXPERIMENTALLY OBTAINED COMBUSTOR PARAMETERS. H. Rudolph Dettwyler and Maxime A. Faget. August 1953. 44p. diagrs., tab. (NACA RM L53E21)

A parameter is presented which simplifies the accounting for pressure losses in ram-jet combustors. The parameter, called the combustor-force coefficient, relates the ratio of the jet force and the total pressure at the combustion-chamber entrance. Experimental data for seven different combustors are presented for evaluation and comparisons. A calculation method is presented which reduces the ram-jet thrust equation to linear relationships and leads to a short method for determination of the proper ram-jet free-stream tube area.

NACA RM L53F02

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECT OF MODIFICATIONS TO AN INDENTED BODY IN COMBINATION WITH A 45° SWEPTBACK WING. Donald L. Loving. September 1953. 29p. diagrs., photos., tabs. (NACA RM L53F02)

A force-test investigation was conducted at transonic speeds on wing-body combinations having indented bodies which were modified from the symmetrical

DECLASSIFIED NACA RESEARCH REPORTS

shape designed on the basis of the transonic drag-rise rule. The wing of the combination had 45° sweepback, an aspect ratio of 4, a taper ratio of 0.6, and NACA 65A006 airfoil sections parallel to the plane of symmetry. The modified indentations were designed specifically to improve the transonic drag characteristics of the wing-body combinations at lifting conditions as well as for the nonlifting case.

NACA RM L53F05

AN INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS AT TRANSONIC MACH NUMBERS OF A SWEPT-WING SUPERSONIC BOMBER CONFIGURATION. Ralph P. Bielat and J. Lawrence Cooper. February 1956. 92p. diagrs., photos., tabs. (NACA RM L53F05)

An investigation of a swept-wing supersonic bomber configuration has been made at transonic speeds in the Langley 8-foot transonic tunnel. The wing had an aspect ratio of 3.5, a taper ratio of 0.2, 47° sweepback of the 0.25-chord line, and airfoil sections which were 5.5 percent thick parallel to the plane of symmetry. The results reported consist of the longitudinal force characteristics of the complete model and of various combinations of its components. The Mach number range extended from 0.70 to approximately 1.11, and the Reynolds number based on the wing mean aerodynamic chord varied from 2.60×10^6 to 2.95×10^6.

NACA RM L53F23

EFFECTS OF LEADING-EDGE SLATS ON THE AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK WING-FUSELAGE CONFIGURATION AT MACH NUMBERS OF 0.4 TO 1.03. Jack F. Runckel and Seymour Steinberg. August 1953. 50p. diagrs., photos. (NACA RM L53F23)

Aerodynamic characteristics of a 45° sweptback wing-fuselage combination with outboard leading-edge slats of 45 percent semispan and 0°, 10°, and 20° slat deflection, and 35 percent-semispan slats having 0° and 10° deflection are presented for Mach numbers from 0.4 to 1.03. Improved performance at high lift coefficients was demonstrated with the slat configurations tested.

NACA RM L53G03a

MEASUREMENTS OBTAINED DURING THE GLIDE-FLIGHT PROGRAM OF THE BELL X-2 RESEARCH AIRPLANE. Richard E. Day. July 30, 1953. 27p. diagrs., photos., tabs. (NACA RM L53G03a)

Results obtained during the glide-flight program of the Bell X-2 research airplane are presented. Limited measurements of flying qualities, landing data, and pilot's comments obtained from the three glide flights are presented.

NACA RM L53I17

SOME MEASUREMENTS OF BUFFETING ENCOUNTERED BY A DOUGLAS D-558-II RESEARCH AIRPLANE IN THE MACH NUMBER RANGE FROM 0.5 TO 0.95. Thomas F. Baker. November 1953. 22p. diagrs., photos., tabs. (NACA RM L53I17)

Measurements of the intensity of buffeting were made with a swept-wing Douglas D-558-II research airplane at subsonic speeds. The variation of buffet intensity with lift, angle of attack, and Mach number is presented. The results are compared with similar measurements made with another Douglas D-558-II airplane at high subsonic and supersonic speeds.

NACA RM L53I22

STATIC LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 1/16-SCALE MODEL OF THE DOUGLAS D-558-II RESEARCH AIRPLANE AT MACH NUMBERS OF 1.61 AND 2.01. M. Leroy Spearman. November 1953. 34p. diagrs., tabs. (NACA RM L53I22)

The static longitudinal stability and control characteristics of a 1/16-scale model of the D-558-II research airplane are presented for Mach numbers of 1.61 and 2.01. Various combinations of component parts were investigated through an angle-of-attack range from -4° to about 16°. Summary figures are presented to show the variation of certain aerodynamic parameters through a Mach number range from 0.6 to 2.0.

NACA RM L53I22b

DRAG DUE TO LIFT AT MACH NUMBERS UP TO 2.0. Edward C. Polhamus. November 1953. 18p. diagrs. (NACA RM L53I22b)

This report presents a summary of some of the more recent data on drag due to lift at Mach numbers up to 2.0. It includes the effect of Reynolds number, thickness ratio, leading-edge radius, aspect ratio, surface shape, and application of the "area rule."

NACA RM L53I29a

STATIC LATERAL STABILITY CHARACTERISTICS OF A 1/16-SCALE MODEL OF THE DOUGLAS D-558-II RESEARCH AIRPLANE AT MACH NUMBERS OF 1.61 AND 2.01. Frederick C. Grant and Ross B. Robinson. November 1953. 39p. diagrs., photo., tabs. (NACA RM L53I29a)

Static lateral stability characteristics of the complete 1/16-scale model of the Douglas D-558-II research airplane are presented along with the characteristics without wings and without vertical tail and for the body alone. The test Mach numbers were 1.61 and 2.01. The test angles of attack were 0° and 4° at each Mach number. Tables of the static-stability derivatives for the complete and partial models are tabulated and comparisons with flight and theoretical results are made.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L53J20

DETERMINATION OF LONGITUDINAL STABILITY IN SUPERSONIC ACCELERATED MANEUVERS FOR THE DOUGLAS D-558-II RESEARCH AIRPLANE. Herman O. Ankenbruck. February 1954. 29p. diagrs., photos., tab. (NACA RM L53J20)

Flight tests were performed with the Douglas D-558-II research airplane to investigate the longitudinal stability of the airplane in accelerated flight at supersonic speeds to a Mach number of 1.67. This paper shows the conditions where instability occurs at supersonic speeds.

NACA RM L53L10

MEASURED DATA PERTAINING TO BUFFETING AT SUPERSONIC SPEEDS OF THE DOUGLAS D-558-II RESEARCH AIRPLANE. Thomas F. Baker. February 1954. 16p. diagrs., photos., tab. (NACA RM L53L10)

Data pertaining to buffeting have been measured at supersonic speed and high lift with the Douglas D-558-II airplane. Buffeting was encountered at normal-force coefficients greater than about 0.7 in the Mach number range from 0.96 to 1.27 but at a Mach number of 1.57, a peak normal-force coefficient of 0.80 was attained with no indication of buffeting. Buffet intensities at normal-force coefficients up to 1.5 are given for low supersonic Mach numbers. Sample records of flight in rough air at supersonic speed are included.

NACA RM L53L16

EFFECT OF WING SLATS AND INBOARD WING FENCES ON THE LONGITUDINAL STABILITY CHARACTERISTICS OF THE DOUGLAS D-558-II RESEARCH AIRPLANE IN ACCELERATED MANEUVERS AT SUBSONIC AND TRANSONIC SPEEDS. Jack Fischel. February 1954. 125p. diagrs., photos., tabs. (NACA RM L53L16)

The results of subsonic and transonic flight measurements of the longitudinal stability characteristics of the Douglas D-558-II research airplane for several wing-slat and inboard wing-fence configurations are presented at Mach numbers up to 1.0. The improvement provided by fully extended slats, compared to the stability characteristics of the slats-retracted configuration, is shown; and the effects of inboard wing fences on the stability characteristics with slats fully extended are also discussed. Limited data obtained with slats half extended indicated the similarity of this configuration to the slats-retracted configuration. The effects of a bungee (which improved the stick-free stability characteristics) in alleviating the stability changes apparent to the pilot are also discussed.

NACA RM L54F01

THE HYDRODYNAMIC PLANING LIFT OF FOUR SURFACES AS MEASURED IN A 200-FPS FREE JET. John R. McGehee, Bernard Weinflash, and Charles A. Pelz. July 1954. 24p. diagrs., photos. (NACA RM L54F01)

Four types of planing surfaces were tested on a rectangular free-water jet 3 inches wide by 3/4 inch deep at speeds varying from 80 to 200 fps. No large effect of speed was obtained on any of the models tested but the lift coefficients for the flat plate and the longitudinally curved surface appeared to increase slightly with speed in the higher portion of the speed range. The lift data for the flat plate and the hydroski obtained on the free-water jet were less than those obtained for similar surfaces in comparatively unrestricted towing tanks. For the trims and length-beam ratios investigated, the ratio of tank lift data to jet lift data for the flat plate appeared to be a function of the ratio of the height of the trailing edge of the model above the lower jet boundary to the wetted length.

NACA RM L54F02

EXPLORATORY INVESTIGATION OF EXTERNAL STORES ON THE AERODYNAMIC CHARACTERISTICS OF A 1/16-SCALE MODEL OF THE DOUGLAS D-558-II RESEARCH AIRPLANE AT A MACH NUMBER OF 2.01. Norman F. Smith. August 1954. 25p. diagrs., photos. (NACA RM L54F02)

As part of a coordinated investigation of stores on the Douglas D-558-II research airplane in the wind tunnel and in flight, an investigation has been conducted in the Langley 4- by 4-foot supersonic pressure tunnel at a Mach number of 2.01 on a 1/16-scale model of this airplane equipped with various store configurations. The investigation was exploratory in nature and shows overall effects of stores upon the airplane characteristics but does not provide breakdown data necessary to isolate these effects. The drag produced by addition of stores was high for all configurations and is shown to be consistent with values measured in previous investigations for stores in similar positions. Changes in other forces and moments were moderate with the exception of directional stability, which was decreased by one-third by the addition of stores.

NACA RM L54F03

LIFT AND DRAG CHARACTERISTICS OF THE DOUGLAS D-558-II RESEARCH AIRPLANE OBTAINED IN EXPLORATORY FLIGHTS TO A MACH NUMBER OF 2.0. Jack Nugent. August 1954. 20p. diagrs., photo., tab. (NACA RM L54F03)

A flight investigation was made of the Douglas D-558-II swept-wing airplane in the slats-retracted configuration. Lift and drag were determined for Mach numbers up to 2.0. The lift-coefficient range extended from below 0.1 to about 0.7.

NACA RM L54F09

WIND-TUNNEL INVESTIGATION AT A MACH NUMBER OF 2.01 OF THE AERODYNAMIC CHARACTERISTICS IN COMBINED PITCH AND SIDESLIP OF SOME CANARD-TYPE MISSILES HAVING CRUCIFORM WINGS AND CANARD SURFACES WITH 70° DELTA PLAN FORMS. M. Leroy Spearman and Cornelius Driver. August 1954. 121p. diagrs., tabs. (NACA RM L54F09)

An investigation has been conducted in the Langley 4- by 4-foot supersonic pressure tunnel to determine the static longitudinal stability and control characteristics of several missiles at a Mach number of 2.01. The missiles had cruciform wings and canard surfaces of delta plan form with the leading edges swept 70°. Two models were tested with body fineness ratios of 19.1 and 15.7. The results of the tests are presented for an incidence angle range from -2° to about 26° at various roll angles from 0° to 90°. A resolution of these results provides the aerodynamic characteristics for the missiles at angles of attack up to about 26° at zero sideslip or at combinations of angle of attack and angle of sideslip up to a maximum of about 16° for each.

NACA RM L54F14

INVESTIGATION OF THE EFFECT OF INDENTATION ON AN M-PLAN-FORM-WING—BODY COMBINATION AT TRANSONIC SPEEDS. Donald L. Loving. August 1954. 24p. diagrs., photos., tab. (NACA RM L54F14)

An investigation at transonic speeds was conducted to determine the effect of body indentation on the aerodynamic characteristics of an M-wing—body combination. In addition, a sweptback wing was tested. The wings had 45° of sweep of the quarter-chord line, aspect ratio 6, taper ratio 0.6, and NACA 65A009 airfoil sections parallel to the free stream. Data were obtained at angles of attack from 0° to 12° for a Mach number range from 0.80 to 1.13.

NACA RM L54F15

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. STABILITY AND CONTROL CHARACTERISTICS AT A MACH NUMBER OF 1.61 OF THE COMPLETE CONFIGURATION EQUIPPED WITH SPOILERS. Clyde V. Hamilton and Cornelius Driver. September 1954. 28p. diagrs. (NACA RM L54F15)

Six-component force tests were made in the Langley 4- by 4-foot supersonic pressure tunnel to determine the static stability and control characteristics at a Mach number of 1.61 of a supersonic aircraft configuration equipped with spoilers. Tests were made at angles of attack from -8° to 16° and angles of sideslip from -8° to 8°. Some effects of various types of spoilers, spoiler span, projection, and chordwise position were also investigated.

NACA RM L54F21

A METHOD FOR INCREASING THE EFFECTIVENESS OF STABILIZING SURFACES AT HIGH SUPERSONIC MACH NUMBERS. Charles H. McLellan. August 1954. 14p. diagrs. (NACA RM L54F21)

Large increases in lift-curve slope at low angles of attack at high supersonic Mach numbers can be obtained by the use of wedge-shape airfoil sections. The use of such sections on the tail surfaces operating at low angles of attack on airplanes or missiles traveling at these speeds can greatly decrease the stabilizing-surface area required. Moderate increases in section effectiveness (lift-curve slope) over that for more conventional tail sections can be obtained with little or no increase in total drag because of the decreased surface area required. Larger increases can be obtained; however, they will be accompanied by increases in stabilizing-surface drag.

NACA RM L54F25

EFFECTS OF CANOPY, REVISED VERTICAL TAIL, AND A YAW-DAMPER VANE ON THE AERODYNAMIC CHARACTERISTICS OF A 1/16-SCALE MODEL OF THE DOUGLAS D-558-II RESEARCH AIRPLANE AT A MACH NUMBER OF 2.01. Ross B. Robinson. August 1954. 29p. diagrs., tabs. (NACA RM L54F25)

The aerodynamic characteristics in pitch and sideslip with and without a yaw-damper vane of a revised 1/16-scale model of the Douglas D-558-II research airplane are presented for a Mach number of 2.01. The model was tested through an angle-of-attack range of -2° to about 13° at an angle of sideslip of 0° and an angle-of-sideslip range of -2° to about 10° at an angle of attack of 0°. The results are compared with those previously obtained for the original model configuration.

NACA RM L54G26a

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. STATIC LONGITUDINAL AND LATERAL STABILITY AND CONTROL CHARACTERISTICS AT A MACH NUMBER OF 1.89. M. Leroy Spearman and Edward B. Palazzo. October 1954. 24p. diagrs., photo., tab. (NACA RM L54G26a)

The static longitudinal and lateral stability and control characteristics of a supersonic aircraft configuration are presented for a Mach number of 1.89. The configuration had a wing with 40° sweepback at the quarter-chord line, aspect ratio 4, taper ratio 0.5, and 10-percent-thick circular-arc sections normal to the quarter-chord line. The angle-of-attack range varied from -4° to 28° and the angle of sideslip range varied from -4° to 44°. The results are compared with results previously obtained for Mach numbers of 1.40 to 1.59.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L54H19

AN INVESTIGATION OF A SUPERSONIC AIRCRAFT CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. AERODYNAMIC CHARACTERISTICS OF THE CONFIGURATION EQUIPPED WITH A CANARD CONTROL SURFACE AT A MACH NUMBER OF 1.89. M. Leroy Spearman and Edward B. Palazzo. October 1954. 22p. diagrs., photo., tab. (NACA RM L54H19)

The aerodynamic characteristics at a Mach number of 1.89 are presented for a supersonic aircraft configuration equipped with a canard control surface in addition to a conventional horizontal stabilizer. The configuration had a wing with 40° sweepback at the quarter-chord line, aspect ratio 4, taper ratio 0.5, and 10-percent-thick circular-arc sections normal to the quarter-chord line. The canard had a trapezoidal plan form with an exposed area about one-twelfth of the wing area and was located 2.27 mean aerodynamic chord lengths ahead of the reference center of gravity. The angle-of-attack range varied from -4° to 28° and the angle-of-sideslip range varied from -4° to 44° at $\alpha = 0°$ only.

NACA RM L54L10

EFFECTS OF INCREASING REYNOLDS NUMBER FROM 2×10^6 TO 6×10^6 ON THE AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF A 45° SWEPT WING WITH 6° LEADING-EDGE DROOP. James W. Schmeer and J. Lawrence Cooper. February 1955. 22p. diagrs., photo. (NACA RM L54L10)

An investigation has been made in the Langley 16-foot and 8-foot transonic tunnels to determine the effects of Reynolds number on the aerodynamic characteristics of a 45° swept wing with 6° leading-edge droop. Lift, drag, and pitching-moment results are presented at Reynolds numbers of about 2×10^6 and 6×10^6 through a Mach number range from 0.80 to 1.03. The effects of roughness strips were also investigated. The results showed only small effects of increasing Reynolds number or of adding roughness strips.

NACA RM L55A31

LATERAL STABILITY CHARACTERISTICS AT LOW LIFT BETWEEN MACH NUMBERS OF 0.85 AND 1.15 OF A ROCKET-PROPELLED MODEL OF A SUPERSONIC AIRPLANE CONFIGURATION HAVING A TAPERED WING WITH CIRCULAR-ARC SECTIONS AND 40° SWEEPBACK. Charles T. D'Aiutolo and Allen B. Henning. April 1955. 50p. diagrs., photos., tabs. (NACA RM L55A31)

A rocket-propelled model of a supersonic airplane configuration employing a 40° sweptback wing having circular-arc sections was tested in the Mach number range of 0.85 and 1.15 to obtain lateral stability data at low lift from the lateral response due to an impulsive rudder deflection. The model was statically stable throughout the Mach number range but was dynamically unstable over a small range of Mach numbers. A low-lift buffet was experienced below a Mach number of 0.95. An analysis of the Dutch roll transient oscillations was performed by the time-vector method to obtain the lateral stability derivatives C_{Y_β}, C_{n_β}, C_{l_β}, C_{l_r}, and $C_{n_r} - C_{n_{\dot\beta}}$. Comparisons were made with other data in order to evaluate the test technique.

NACA RM L55E18

ANALYSIS OF EFFECTS OF AIRPLANE CHARACTERISTICS AND AUTOPILOT PARAMETERS ON A ROLL-COMMAND SYSTEM WITH AILERON RATE AND DEFLECTION LIMITING. Albert A. Schy and Ordway B. Gates, Jr. September 1955. 68p. diagrs., tab. (NACA RM L55E18)

The dynamic characteristics of an airplane with a proportional-gain roll-control autopilot are discussed. The significant aspects of the dynamic characteristics of the airplane are analyzed. A comparison of three different high-speed fighter airplanes is presented. The dynamic effects of time lags and various gains in the system are described. REAC results are presented to show the results of limiting the aileron deflection and rate of deflection on the dynamic characteristics of the system.

NACA RM L55F01b

A FLIGHT INVESTIGATION OF THE HANDLING CHARACTERISTICS OF A FIGHTER AIRPLANE CONTROLLED THROUGH AUTOMATIC-PILOT CONTROL SYSTEMS. S. A. Sjoberg. September 1955. 12p. diagrs., tabs. (NACA RM L55F01b)

The paper presents some results of a flight investigation made to obtain experimental information on the handling qualities of a fighter airplane controlled through automatic-pilot control systems. Two types of automatic pilots were used; one of these was of the attitude type and the other was of the rate type.

NACA RM L55F02a

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE STATIC LONGITUDINAL CHARACTERISTICS OF A 3-PERCENT-THICK, ASPECT-RATIO-3, DELTA WING CAMBERED AND TWISTED FOR HIGH LIFT-DRAG RATIOS. Dale L. Burrows and Warren A. Tucker. August 1955. 38p. diagrs., photos., tab. (NACA RM L55F02a)

A transonic wind-tunnel investigation at Mach numbers from 0.77 to 1.39 was made at angles of attack to 20° and at Reynolds numbers of about 5×10^6 of a 3-percent-thick, aspect-ratio-3, delta wing cambered and twisted for near optimum lift-drag ratios at the design condition of Mach number equal to 1.2 and lift coefficient equal to 0.2. The results when compared with the same wing without camber and

DECLASSIFIED NACA RESEARCH REPORTS

twist indicate appreciable improvements in drag at lifting conditions and increase in lift-curve slope in the subsonic range and in the region of the design Mach number.

NACA RM L55F07

HIGH-SPEED CASCADE TESTS OF A BLADE SECTION DESIGNED FOR TYPICAL HUB CONDITIONS OF HIGH-FLOW TRANSONIC ROTORS. Melvyn Savage, A. Richard Felix, and James C. Emery. September 1955. 48p. diagrs., photos., tab. (NACA RM L55F07)

High-speed cascade tests were made of a blade section designed specifically for conditions typical of the hub section of high-flow transonic rotors. The blade section has a camber of 1.8, a maximum thickness of 8 percent, an arbitrarily selected A_6I_{4b} mean line (which has more of its loading in the rearward portion of the blade), and a thickness distribution which has its maximum thickness at the 65-percent-chord point and is somewhat similar to the NACA 65-series thickness distribution reversed. The tests were made at four combinations of inlet angle and angle of attack at a solidity of 1.5. The inlet angles ranged from 26.9° to 34.1°. Measurements of surface pressure distribution, profile momentum loss, and turning angle, as well as schlieren photographs, were made for inlet Mach numbers ranging from 0.30 to the blade choke condition.

NACA RM L55F09a

A FREE-FLIGHT INVESTIGATION OF THE EFFECTS OF SIMULATED SONIC TURBOJET EXHAUST ON THE DRAG OF A BOATTAIL BODY WITH VARIOUS JET SIZES FROM MACH NUMBER 0.87 TO 1.50. Ralph A. Falanga. August 1955. 23p. diagrs., photos., tab. (NACA RM L55F09a)

Three 7.5° boattail bodies of revolution with varying base-annulus areas and jet sizes provided with simulated-turbojet-exhaust rocket motors were flight tested to determine the jet interference effects on body drag over a Mach number range from approximately 0.87 to 1.5. It was found that, in the transonic and low supersonic speed range, the jet caused positive pressure increments on the base and boattail which appreciably reduced the configuration drag from the power-off condition; whereas at the higher supersonic speeds, the jet caused positive pressure increments only on the base resulting in a smaller drag reduction.

NACA RM L55F22a

INVESTIGATION AT TRANSONIC SPEEDS OF AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT SEMIELLIPTICAL AIR INLET IN THE ROOT OF A 45° SWEPTBACK WING. Gene J. Bingham. September 1955. 37p. diagrs., photos., tabs. (NACA RM L55F22a)

An investigation has been made in the Langley transonic blowdown tunnel at Mach numbers from 0.65 to 1.40 to study the internal and external aerodynamic characteristics of an unswept semielliptical air intake with 30° lip stagger installed in the root of a 45° sweptback wing. Tests were made through an angle-of-attack range from 0° to 9.6° at mass-flow ratios from about 0.55 to 0.90. The results of this investigation have been compared with those of a similar inlet swept back along the wing leading edge. Increases in compressor-face total-pressure recovery with decreasing mass-flow ratio were effected at all test conditions because of a "natural" bypassing of the fuselage boundary layer around the inlet. This unusual phenomenon resulted in normal-shock recovery at a mass-flow ratio of 0.65 for a Mach number of 1.40.

NACA RM L55F23

AERODYNAMIC CHARACTERISTICS AT MACH NUMBERS FROM 0.7 TO 1.75 OF A FOUR-ENGINE SWEPT-WING AIRPLANE CONFIGURATION AS OBTAINED FROM A ROCKET-PROPELLED MODEL TEST. Rowe Chapman, Jr. September 1955. 39p. diagrs., photos., tabs. (NACA RM L55F23)

Drag and stability data obtained from free-flight test of a rocket-propelled model of a swept-wing airplane configuration are presented for Mach numbers from 0.70 to 1.75. The configuration had four nacelles closely coupled underneath the wing for which pressure recovery, mass flow, and internal drag data are presented. Test data cover lift coefficients from 0 to 0.40 at subsonic speeds and -0.05 to 0.12 at supersonic speeds. Results from the present test are compared with unpublished data from tunnel tests of similar configurations.

NACA RM L55F27

LONGITUDINAL CHARACTERISTICS AT TRANSONIC AND SUPERSONIC SPEEDS OF A ROCKET-PROPELLED AIRPLANE MODEL HAVING A 60° DELTA WING AND A LOW SWEPT HORIZONTAL TAIL. Robert F. Peck and Lucille C. Coltrane. September 1955. 33p. diagrs., photo., tabs. (NACA RM L55F27)

A rocket-propelled model has been flown to determine the longitudinal stability and drag characteristics of an airplane configuration having a 60° delta wing (with an NACA 65A003 airfoil section) and a swept horizontal tail mounted near the wing plane extended. Comparisons are made between this model and a

DECLASSIFIED NACA RESEARCH REPORTS

model with the same wing-fuselage combination but with a horizontal tail considerably above the wing plane extended. Comparisons are also made with two models with the same fuselage-tail arrangement as the present test model but one with a 52.5° delta wing and the other with a diamond wing.

NACA RM L55H16

WIND-TUNNEL MEASUREMENTS OF THE DYNAMIC CROSS DERIVATIVE $C_{l_r} - C_{l_{\dot{\beta}}}$ (ROLLING MOMENT DUE TO YAWING VELOCITY AND TO ACCELERATION IN SIDESLIP) OF THE DOUGLAS D-558-II AIRPLANE AND ITS COMPONENTS AT SUPERSONIC SPEEDS INCLUDING DESCRIPTION OF THE TECHNIQUE. William B. Boatright. November 1955. 57p. diagrs., photos. (NACA RM L55H16)

A technique is described and results are presented of wind-tunnel forced-oscillation tests of a model of the Douglas D-558-II research airplane instrumented to obtain the dynamic cross derivative, rolling moment due to yawing velocity and to acceleration in sideslip $C_{l_r} - C_{l_{\dot{\beta}}}$, and the static rolling moment due to sideslip C_{l_β}. The tests were conducted at Mach numbers 1.62, 1.94, and 2.41 for an angle-of-attack range from 0° to 8°. Results of the component tests of the body wing and the body tail, which were made at Mach numbers 1.62 and 2.41, are also presented.

NACA RM L55I07

TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF EXTERNAL STORES AND STORE POSITION ON THE AERODYNAMIC CHARACTERISTICS OF A 1/16-SCALE MODEL OF THE DOUGLAS D-558-II RESEARCH AIRPLANE. Thomas C. Kelly. November 1955. 31p. diagrs., photos., tab. (NACA RM L55I07)

Tests have been conducted in the Langley 8-foot transonic tunnel at Mach numbers from 0.60 to 1.15 and angles of attack from approximately -2° to 12° to study the effects of adding pylon-suspended external stores to a 1/16-scale model of the Douglas D-558-II research airplane. Results indicate that the drag penalty incurred by adding external stores at the 0.61-semispan location may be reduced slightly at transonic speeds by positioning the stores at the 0.44-semispan location in order to obtain an improvement in the longitudinal area development.

NACA RM L56E25

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF JET, SPOILER, AND AILERON CONTROLS ON A 1/16-SCALE MODEL OF THE DOUGLAS D-558-II RESEARCH AIRPLANE. Raymond D. Vogler. July 1956. 52p. diagrs., photo., tabs. (NACA RM L56E25)

An investigation of jet, spoiler, and aileron controls on a 1/16-scale model of the D-558-II research airplane has been made in the Langley high-speed 7- by 10-foot tunnel at Mach numbers from 0.60 to 0.96. All controls gave considerable effectiveness through the angle-of-attack range though much less above 12° than at small angles of attack. The jet control with the jet holes located at the wing trailing edge and supplied with ram air from wing-tip inlets gave constant effectiveness through the Mach range while the ailerons and spoilers decreased between Mach numbers 0.90 and 0.96. Data were obtained for variations in jet-control span and jet diameter, and for drag comparisons of the three controls.

NACA RM L56F07

WIND-TUNNEL INVESTIGATION OF THE DAMPING IN ROLL OF THE DOUGLAS D-558-II RESEARCH AIRPLANE AND ITS COMPONENTS AT SUPERSONIC SPEEDS. Russell W. McDearmon. September 1956. 36p. diagrs., photos. (NACA RM L56F07)

Investigations of the damping in roll at zero angle of attack of the Douglas D-558-II research airplane have been made in the Langley 9-inch supersonic tunnel. The damping in roll of the complete configuration and the contributions of the components to the damping in roll were measured at Mach numbers of 1.62, 1.94, 2.22, 2.41, and 2.62. Also, some effects of Reynolds number, boundary layer, wing-incidence angle, and the canopy on the damping in roll were determined. Comparisons were made with some theoretical predictions.

NACA RM L56F07a

RESULTS FROM AN INVESTIGATION IN ROUGH AIR AT MACH NUMBERS FROM 0.84 TO 1.67 OF A TAILLESS ROCKET MODEL HAVING 60° TRIANGULAR WINGS. A. James Vitale. July 1956. 16p. diagrs., photo., tab. (NACA RM L56F07a)

A flight investigation has been made in rough air from Mach numbers 0.84 to 1.67 of a tailless rocket model having cruciform 60° triangular wings. Test results are presented in the form of time histories of acceleration, power spectra of acceleration, and the variation of root-mean-square acceleration increment with Mach number.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L56F11

HINGE MOMENT AND EFFECTIVENESS OF AN UNSWEPT CONSTANT-CHORD CONTROL AND AN OVERHANG-BALANCED, SWEPT HINGE-LINE CONTROL ON AN 80° SWEPT POINTED WING AT MACH NUMBERS FROM 0.75 TO 1.96. Lawrence D. Guy. August 1956. 39p. diagrs., photo. (NACA RM L56F11)

A wind-tunnel investigation has been made of an unswept constant-chord control and an overhang-balanced, swept hinge-line control on an 80° swept pointed wing. Control hinge moment and effectiveness characteristics were obtained for control deflections up to 25° over an angle-of-attack range of ±16° at Mach numbers from 0.75 to 1.96. Reynolds numbers varied between 3.2×10^6 and 4.4×10^6.

NACA RM L56F13a

WIND-TUNNEL INVESTIGATION OF DAMPING IN ROLL AT SUPERSONIC SPEEDS OF TRIANGULAR WINGS AT ANGLES OF ATTACK. Russell W. McDearmon and Robert A. Jones. September 1956. 32p. diagrs., photos., tab. (NACA RM L56F13a)

The damping in roll of three triangular wings has been obtained in the Langley 9-inch supersonic tunnel at Mach numbers of 1.62, 1.94, 2.22, 2.41, and 2.62 over a range of angle of attack of approximately 0° to 13°. Comparisons are made with predictions of the damping in roll from linear theory. Angle of attack had no significant effect on the damping in roll for the range of angles of attack investigated.

NACA RM L56F15

INVESTIGATION OF SPOILER-SLOT-DEFLECTOR AILERONS AND OTHER SPOILER AILERONS ON A 45° SWEPTBACK-WING—FUSELAGE COMBINATION AT MACH NUMBERS FROM 0.60 TO 1.03. F. E. West, Jr., Charles F. Whitcomb, and James W. Schmeer. September 1956. 59p. diagrs., tab. (NACA RM L56F15)

Tests were made in the Langley 16-foot transonic tunnel to evaluate several types of spoiler ailerons. Six-component force and moment data were obtained on a 45° sweptback-wing—body combination at Mach numbers from 0.60 to 1.03 (Reynolds number from 5.05×10^6 to 6.0×10^6) and angles of attack from 0° to about 20°. Variations in configuration included: removal of small inboard segments from a flap-type spoiler, spoiler-slot-deflector ailerons with different length deflectors, changes in projection of a deflector aileron, and addition of wing leading-edge chord-extensions.

NACA RM L56F18

LOW-SPEED INVESTIGATION OF THE LATERAL-CONTROL CHARACTERISTICS OF A FLAP-TYPE SPOILER AND A SPOILER-SLOT-DEFLECTOR ON A 30° SWEPTBACK WING-FUSELAGE MODEL HAVING AN ASPECT RATIO OF 3, A TAPER RATIO OF 0.5, AND NACA 65A004 AIRFOIL SECTION. Alexander D. Hammond. August 1956. 25p. diagrs., tab. (NACA RM L56F18)

A wind-tunnel investigation was made at low speed to determine the effect of deflector projection on the control effectiveness of spoiler-slot-deflectors on a 30° sweptback wing-fuselage model equipped with a 15-percent-chord spoiler, slot, and deflector that extended from the 20- to the 99-percent semispan station of the right wing. The tests were made at angles of attack from -4° to 24° at a Mach number of 0.26, which corresponds to a Reynolds number of 2.6×10^6, and for control projections from 0 to 12 percent of the wing chord. The deflector of the spoiler-slot-deflector configurations was tested at projections from zero to a projection equal to the spoiler projection at each control projection.

NACA RM L56F21

TRANSONIC WIND-TUNNEL INVESTIGATION OF STATIC LONGITUDINAL FORCE AND MOMENT CHARACTERISTICS OF TWO WING-BODY COMBINATIONS WITH CLIPPED-TIP AND FULL DELTA WINGS OF ASPECT RATIO 1.73. Dale L. Burrows. September 1956. 26p. diagrs. (NACA RM L56F21)

Wind-tunnel tests at Mach numbers from 0.76 to 1.39 have been made on two low-aspect-ratio wing-body combinations to obtain lift, drag, and pitching-moment data at angles of attack up to 20° and at Reynolds numbers up to about 7×10^6. A 4-percent-thick clipped delta wing (taper ratio 0.4) and a 3-percent-thick full delta wing were tested. In general, the full delta wing had better drag and pitching-moment characteristics but lower lift-curve slopes as compared with clipped wing.

NACA RM L56F21a

STATISTICAL MEASUREMENTS OF LANDING CONTACT CONDITIONS OF FIVE MILITARY AIRPLANES DURING ROUTINE DAYTIME OPERATIONS. Norman S. Silsby. August 1956. 17p. diagrs., tabs. (NACA RM L56F21a)

Statistical measurements of contact conditions have been obtained by means of a special photographic technique of about 100 to 300 landings for each of five military airplanes made during routine daytime operations in clear air. The types were the Lockheed F-94C jet interceptor, the Republic F-84F jet fighter bomber, the Lockheed T-33 jet trainer, the Martin B-57 jet bomber, and the Douglas B-26 twin-propeller bomber. Vertical velocities, bank angles, rolling velocities, and airspeeds at the instant before contact, and touchdown locations from the start of the 8,000-foot runway have been evaluated. A limited statistical analysis of the results has been made.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L56J03

STATIC LONGITUDINAL CHARACTERISTICS AT HIGH SUBSONIC SPEEDS OF A COMPLETE AIRPLANE MODEL WITH A HIGHLY TAPERED WING HAVING THE 0.80 CHORD LINE UNSWEPT AND WITH SEVERAL TAIL CONFIGURATIONS. Kenneth W. Goodson. January 1957. 57p. diagrs., photo., tabs. (NACA RM L56J03)

The present paper presents static longitudinal stability characteristics at high subsonic speeds of a wing-fuselage model having an aspect-ratio-4.0 wing with zero taper and an unswept 0.80 chord line. The pointed wing was modified by clipping small portions off the wing tips to form wings with aspect ratios of 3.50, 3.25, and 3.00. The aspect-ratio-3.50 wing was extensively tested as a complete model with various horizontal and vertical-tail combinations. The tail configurations consisted of a chord-plane horizontal tail, a high or T-tail configuration, and a combined T-tail and chord-plane tail (biplane tail) configuration.

NACA RM L56K02

INVESTIGATION OF THE INFLUENCE OF THE BOUNDARIES OF A HIGH-SPEED FREE WATER JET ON THE PLANING LIFT OF A FLAT PLATE. John R. McGehee. March 1957. 21p. diagrs., photos. (NACA RM L56K02)

In order to determine the influence of the boundaries of a high-speed free water jet on planing lift, a flat plate was tested in jets having a constant width and variable depths, a constant depth and variable widths, and was also tested in Langley tank no. 2, which has relatively great depth and great width. No appreciable influence of speed on the planing lift coefficient for speeds from 50 to 200 feet per second was observed. Apparently, a jet having a width of three model beams and a depth of two model beams is sufficient to give the equivalent of tank planing data obtained from the same size model for the range of parameters covered in this investigation.

NACA RM L57F25

EFFECT OF NOSE SHAPE ON SUBSONIC AERODYNAMIC CHARACTERISTICS OF A BODY OF REVOLUTION HAVING A FINENESS RATIO OF 10.94. Edward C. Polhamus. August 1957. 29p. diagrs. (NACA RM L57F25)

The effect of nose shape on the aerodynamic characteristics of a body of revolution having a fineness ratio of 10.94 is presented for Mach numbers up to 0.90 and angles of attack up to 22°. Six different nose shapes which were investigated included flat-faced noses having various corner radii, a hemispherical nose, and two ogival noses.

NACA RM L57I06

EFFECT OF BOUNDARY SOLIDITY ON PLANING LIFT OBTAINED IN A HIGH-SPEED WATER JET WITH A SINGLE LONGITUDINAL SLOT IN EACH RIGID BOUNDARY. Bernard Weinflash. October 1957. 27p. diagrs., photos. (NACA RM L57I06)

Hydrodynamic planing-lift forces were obtained with a 0.72-inch-beam flat plate at speeds of 200 and 100 feet per second in a rectangular jet 3.00 inches wide and 1.50 inches deep for trims and length-beam ratios corresponding to drafts up to 100 percent of the jet depth. The jet had rigid side and bottom boundaries with longitudinal-slot configurations varying from 0 to 100 percent in solidity. At a solidity of about 72 percent all the jet data were within 5 percent of the infinite-boundary values. No significant difference was noted between data obtained at 200 and at 100 feet per second.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1332

SEAT DESIGN FOR CRASH WORTHINESS. I. Irving Pinkel and Edmund G. Rosenberg. 1957. ii, 16p. diagrs., photos., tab. (NACA Rept. 1332. Supersedes TN 3777)

On the basis of deceleration data obtained in full-scale crashes, a description of crash deceleration pulses is presented which is suitable for seat design. Charts are presented for obtaining the maximum deceleration loads experienced by the seat and passenger in response to their crash deceleration pulses. Finally, a method is presented for determining the seat strength, spring stiffness, and deformation beyond the elastic limit required to serve in a crash deceleration pulse of given description. Measurement of passenger decelerations in full-scale laboratory and crash studies shows that the general principles presented in the report apply.

NACA TM 1414

AERODYNAMIC RESEARCH ON FUSELAGES WITH RECTANGULAR CROSS SECTION. (Aerodynamische Untersuchungen an Rümpfen mit rechteckähnlichem Querschnitt.) K. Maruhn. July 1958. 37p. diagrs. (NACA TM 1414. Translation from Jahrbuch 1942 der deutschen Luftfahrtforschung, p. 263-279.)

The two-dimensional flow characteristics around square and rectangular cross sections with rounded edges as calculated by conformal mapping techniques are presented and compared with corresponding results from elliptical and rectangular cross sections. A few examples of the fuselage induced rolling moment due to sideslip are presented.

NACA TN 4085

METHOD OF SPLIT RIGIDITIES AND ITS APPLICATION TO VARIOUS BUCKLING PROBLEMS. P. P. Bijlaard, Cornell University. July 1958. 97p. diagrs., tabs. (NACA TN 4085)

A comprehensive treatise on the method of split rigidities is presented. The method is applied to a number of buckling problems. The accuracy of the method is shown by comparing the results of the method with the results of exact solutions.

NACA TN 4100

VIBRATION SURVEY OF FOUR REPRESENTATIVE TYPES OF AIR-COOLED TURBINE BLADES. Howard F. Calvert and Gordon T. Smith. July 1958. 22p. diagrs., photos., tabs. (NACA TN 4100)

The vibrational characteristics, frequencies, and stresses were determined both with and without coolant flow for four types of air-cooled turbine blades utilized in turbine-cooling research. Two types had a standard 4-inch span and two types had a long 6-1/4 inch span. The blade vibrational frequencies increased from 2 to 3 percent with coolant flow. The standard-span blades exhibited only resonant-type vibrations, whereas the long-span blades vibrated at all engine speeds. Static fatigue tests were also conducted with the same blades used for the engine investigation.

NACA TN 4135

INFLUENCE OF SOLID-BODY ROTATION ON SCREEN-PRODUCED TURBULENCE. Stephen C. Traugott, Johns Hopkins University. August 1958. 100p. diagrs., photos. (NACA TN 4135)

The influence of solid-body rotation on a screen-produced turbulence in a flow between concentric, rotating cylinders has been investigated. Radial distributions of the three components of turbulence intensity and the three turbulent shear stresses were measured at a fixed distance downstream of the screen both with and without rotation. An energy balance is made for the three intensities from measured decay and dissipation terms. In addition, the change of the axial and peripheral mean velocity profiles with distance along the axis of rotation is presented.

NACA TN 4255

WIND-TUNNEL INVESTIGATION AT LOW SPEEDS OF FLIGHT CHARACTERISTICS OF A SWEPTBACK-WING JET-TRANSPORT AIRPLANE MODEL EQUIPPED WITH AN EXTERNAL-FLOW JET-AUGMENTED SLOTTED FLAP. Joseph L. Johnson, Jr. July 1958. 32p. diagrs., photos., tab., film suppl. available on request. (NACA TN 4255)

The investigation was made over a lift-coefficient range up to about 12.5 for a range of angles of attack from -12° to about 13°. For lift coefficients higher than about 6, a downwardly directed nose jet was used to supplement the trimming power of the horizontal tail. Flight characteristics of the model without the nose jet were generally satisfactory up to a lift coefficient of about 4. Flight characteristics of the model with the nose jet were generally satisfactory

CURRENT NACA RESEARCH REPORTS

over the test lift-coefficient range, but the control effectiveness provided by conventional control surfaces was barely sufficient for maintaining flight at a lift coefficient of 12.5.

NACA TN 4277

A BODY MODIFICATION TO REDUCE DRAG DUE TO WEDGE ANGLE OF WING WITH UNSWEPT TRAILING EDGE. William C. Pitts and Jack N. Nielsen. July 1958. 13p. (NACA TN 4277)

This paper considers a term in Ward's slender-body-theory drag formula that is neglected in engineering applications of the transonic area rule. This term depends only upon the cross-sectional shape and surface slopes at the model base, and is therefore independent of the cross-sectional area distribution. For the particular case considered it is found that (neglecting any change in base drag) a drag reduction is obtainable which is an additional 12 percent of that obtained with the area-rule modification. The probable effect of viscosity on this theoretical result is discussed.

NACA TN 4279

EFFECTS OF FIXING TRANSITION ON THE TRANSONIC AERODYNAMIC CHARACTERISTICS OF A WING-BODY CONFIGURATION AT REYNOLDS NUMBERS FROM 2.4 TO 12 MILLION. Lynn W. Hunton. July 1958. 56p. diagrs. (NACA TN 4279)

A wing-body combination having a plane tapered wing of aspect ratio 3 and 3-percent-thick biconvex sections was tested. Lift, drag, and pitching-moment results are shown for Mach numbers from 0.7 to 1.3 and Reynolds numbers from 2.4 to 12 million. The large effects of Reynolds number found for the model were practically eliminated when transition was fixed with a single element wire on both the body and the wings.

NACA TN 4280

PRESSURE DISTRIBUTIONS AT TRANSONIC SPEEDS FOR SLENDER BODIES HAVING VARIOUS AXIAL LOCATIONS OF MAXIMUM DIAMETER. John B. McDevitt and Robert A. Taylor. July 1958. 112p. diagrs., photo. (NACA TN 4280)

The measured static-pressure distributions at the model surface and in the surrounding flow field are presented for a related series of five bodies of revolution having various axial locations of maximum cross-sectional area. The bodies were tested at zero angle of attack through a Mach number range from 0.80 to 1.20.

NACA TN 4282

BOUNDARY-LAYER STABILITY DIAGRAMS FOR ELECTRICALLY CONDUCTING FLUIDS IN THE PRESENCE OF A MAGNETIC FIELD. Vernon J. Rossow. August 1958. 32p. diagrs., tabs. (NACA TN 4282)

Neutral stability curves pertaining to a two-dimensional infinitesimal sinusoidal disturbance are presented for the laminar flow of an incompressible, electrically conducting fluid over a semi-infinite flat plate in the presence of either a coplanar or transverse magnetic field. The magnetic field is found to be stabilizing in all of the cases studied except one.

NACA TN 4294

EFFECTS OF NOSE SHAPE AND SPRAY CONTROL STRIPS ON EMERGENCE AND PLANING SPRAY OF HYDRO-SKI MODELS. John R. McGehee. July 1958. 28p. diagrs., photos. (NACA TN 4294)

The emergence-spray characteristics of the models with various bow shapes were investigated for depths of submersion of the bow from 0.50 inch to -0.50 inch. The planing-spray characteristics of the models with the various deflectors were determined for a draft corresponding to a length-beam ratio of 4. This investigation was performed for trims of 12° and 20° at a speed of 30 feet per second. The emergence-spray and planing-spray patterns are shown in photographs.

NACA TN 4297

FLIGHT INVESTIGATION OF THE ACCEPTABILITY OF A SMALL SIDE-LOCATED CONTROLLER USED WITH AN IRREVERSIBLE HYDRAULIC CONTROL SYSTEM. Helmut A. Kuehnel and Robert W. Sommer. July 1958. 19p. diagrs., photos., tabs. (NACA TN 4297)

Results indicate that the side location of the controller is consistent with pilot comfort and the airplane is flyable with this type of controller. Hand motion pivoting at the wrist is somewhat uncomfortable when large stick deflections and forces are required for longitudinal control. Results are based on the opinions of six pilots and are supported by time-history records of typical flight runs.

NACA TN 4300

HEAT-TRANSFER AND PRESSURE MEASUREMENTS ON FLAT-FACED CYLINDERS AT A MACH NUMBER OF 2. William E. Stoney, Jr., and J. Thomas Markley. July 1958. 38p. diagrs., photos., tab. (NACA TN 4300)

Flat-faced cylinders of 12-inch diameter and 4-inch diameter were tested at a Mach number of 2 and sea-level conditions in a preflight jet. The pressure

CURRENT NACA RESEARCH REPORTS

data from the 4-inch-diameter model agreed well with the results of several other investigations. The stagnation-point pressure gradient was indicated to be about 30 percent of the gradient on a hemisphere of equivalent size. The heat-transfer data agreed reasonably well with the theoretical results when the flow was laminar. The stagnation-point heating rates of a flat face were approximately 55 percent of the stagnation heating rates on a hemisphere of equal diameter.

NACA TN 4305

WIND-TUNNEL INVESTIGATION OF EFFECTS OF SPOILER LOCATION, SPOILER SIZE, AND FUSELAGE NOSE SHAPE ON DIRECTIONAL CHARACTERISTICS OF A MODEL OF A TANDEM-ROTOR HELICOPTER FUSELAGE. James L. Williams. July 1958. 44p. diagrs., photos., tab. (NACA TN 4305)

The results of a low-speed investigation in the Langley stability tunnel on a model of a tandem-rotor helicopter fuselage showed that spoiler size, spoiler location, and fuselage nose shape were important factors in the directional stability characteristics of the fuselage-tail configuration. Tuft-grid pictures showed that the tail operated in an adverse flow field that resulted in a low tail effectiveness.

NACA TN 4312

INTERNAL CHARACTERISTICS AND PERFORMANCE OF AN AERODYNAMICALLY CONTROLLED, VARIABLE-DISCHARGE CONVERGENT NOZZLE. Jack G. McArdle. July 1958. 33p. diagrs., photo., tabs. (NACA TN 4312)

The effective flow area of a convergent exhaust nozzle was reduced as much as 67 percent by injecting a secondary jet into the nozzle near the exit. Analytical expressions relating the performance with significant operating and design variables were developed, and experimental coefficients were evaluated. Some configurations were operated as jet deflectors.

NACA TN 4313

EFFECT OF FAVORABLE PRESSURE GRADIENTS ON TRANSITION FOR SEVERAL BODIES OF REVOLUTION AT MACH 3.12. John R. Jack. July 1958. 28p. diagrs., photo. (NACA TN 4313)

Transition locations on two constant-pressure-gradient models and two power-profile models ($r \propto x^n$) were compared with those from a conventional cone. A constant pressure gradient $[d(p/p_0)/dx]$ of -0.10 per inch increased the distance to transition by a factor of 1.58 times that for a cone, whereas the combined effect of blunting and a favorable pressure gradient increased the distance to transition by a factor of 2.7 times that obtained for a cone. In each case the transition Reynolds number based on local conditions was independent of unit Reynolds number.

NACA TN 4314

ICING FREQUENCIES EXPERIENCED DURING CLIMB AND DESCENT BY FIGHTER-INTERCEPTOR AIRCRAFT. Porter J. Perkins. July 1958. 30p. diagrs., tabs. (NACA TN 4314)

Relative frequencies of occurrence and severity of icing cloud layers encountered up to an altitude of 30,000 feet are presented. Jet fighters on routine operations of the Air Defense Command (USAF) near Duluth, Minnesota, and Seattle, Washington, were equipped with icing meters for 1 year. Icing occurred on approximately 5 percent of the flights, with ice-accretion thickness averaging less than 1/32 inch on a small sensing probe. Probabilities of icing severity (including average liquid-water content and maximum ice accretion) were calculated using earlier data measured in icing clouds.

NACA TN 4315

AN ESTIMATE OF THE FLUCTUATING SURFACE PRESSURES ENCOUNTERED IN THE REENTRY OF A BALLISTIC MISSILE. Edmund E. Callaghan. July 1958. 18p. diagrs. (NACA TN 4315)

An analysis of the sound pressure levels encountered during the reentry of a blunt-nosed vehicle shows the probability of the existence of levels of 150 decibels or more. The exposure time to high levels is short, that is, of the order of 25 seconds. The results are presented in terms of dimensionless parameters, which cover a wide range of conditions in regard to body size and weight and reentrance angle and velocity.

NACA TN 4318

ANALYTICAL RELATION FOR WAKE MOMENTUM THICKNESS AND DIFFUSION RATIO FOR LOW-SPEED COMPRESSOR CASCADE BLADES. Seymour Lieblein. August 1958. 31p. diagrs. (NACA TN 4318)

Presents derivation of simple equation for blade-wake momentum thickness as function of suction-surface diffusion ratio that describes previously reported experimental correlation. Equation is based on boundary-layer theory in conjunction with simplifying approximations and empirical constants. Calculations are made from derived equation to indicate the comparative effects on the limiting diffusion ratio of blade-chord Reynolds number, surface roughness, and location of transition. Results are utilized for discussions of experimental correlations and general blade design considerations.

NACA TN 4329

INFLUENCE OF HEAT TREATMENT ON MICROSTRUCTURE AND HIGH-TEMPERATURE PROPERTIES OF A NICKEL-BASE PRECIPITATION-HARDENING ALLOY. R. F. Decker, John P. Rowe, W. C. Bigelow, and J. W. Freeman, University of Michigan. July 1958. 53p. diagrs., photos., tabs. (NACA TN 4329)

Studies were made of the influence of various heat treatments on the rupture properties and microstructure of a 55Ni-20Cr-15Co-4Mo-3Ti-3Al alloy to

CURRENT NACA RESEARCH REPORTS

provide more fundamental information on the relationships between structure and high-temperature properties in alloys of this type. The effects of variations in solution treatment, cooling rate after solution treatment, and aging treatment on the stress-rupture properties of the alloy at 1,600° F and 25,000 psi were measured and related to variations in the size and distribution of precipitates within the alloy and to residual rolling effects.

NACA TN 4341

LOW-SPEED EXPERIMENTAL DETERMINATION OF THE EFFECTS OF LEADING-EDGE RADIUS AND PROFILE THICKNESS ON STATIC AND OSCILLATORY LATERAL STABILITY DERIVATIVES FOR A DELTA WING WITH 60° OF LEADING-EDGE SWEEP. Herman S. Fletcher. July 1958. 45p. diagrs., photos., tabs. (NACA TN 4341)

Six delta-wing models with 60° of leading-edge sweep were oscillated about their vertical axes to determine the effects of systematic variation of leading-edge radius and profile thickness on the in-phase and out-of-phase combination lateral stability derivatives resulting from the motion. The results showed that, in general, increasing the leading-edge radius caused noticeable decreases in all the derivatives and increasing the airfoil thickness reduced the effective-dihedral parameter.

NACA TN 4351

SUMMARY OF METHODS OF MEASURING ANGLE OF ATTACK ON AIRCRAFT. William Gracey. August 1958. 29p. diagrs. (NACA TN 4351)

Wind-tunnel calibrations of three types of angle-of-attack sensing devices - the pivoted vane, the differential pressure tube, and the null-seeking pressure tube - are presented. Flight data on the position errors of three sensor locations - ahead of the fuselage nose, ahead of the wing tip, and on the forebody of the fuselage - are also presented. Various methods for calibrating angle-of-attack installations in flight are briefly described.

NACA TN 4355

LOW TIP MACH NUMBER STALL CHARACTERISTICS AND HIGH TIP MACH NUMBER COMPRESSIBILITY EFFECTS ON A HELICOPTER ROTOR HAVING AN NACA 0009 TIP AIRFOIL SECTION. Robert D. Powell, Jr., and Paul J. Carpenter. July 1958. 28p. diagrs. (NACA TN 4355)

An investigation has been conducted on the Langley helicopter test tower to determine experimentally the low tip Mach number maximum mean lift coefficient and high tip Mach number compressibility effects on a helicopter rotor having an NACA 0009 airfoil tip section, an NACA 0017 airfoil root section, and 5.4° of negative twist. Data, presented for blade-tip Mach numbers ranging from 0.28 to 0.72 (corresponding blade-tip Reynolds number range of 1.65×10^6 to 4.29×10^6), have been compared with two-dimensional data as well as with other rotor experimental data.

NACA TN 4359

A REVIEW OF THE THERMODYNAMIC, TRANSPORT, AND CHEMICAL REACTION RATE PROPERTIES OF HIGH-TEMPERATURE AIR. C. Frederick Hansen and Steve P. Heims. July 1958. 33p. diagrs. (NACA TN 4359)

Thermodynamic and transport properties of high-temperature air, and the reaction rates for the important chemical processes which occur in air, are reviewed. Semiempirical, analytic expressions are presented for thermodynamic and transport properties of air. Examples are given illustrating the use of these properties to evaluate (1) equilibrium conditions following shock waves, (2) stagnation region heat flux to a blunt, high-speed body, and (3) some chemical relaxation lengths in stagnation region flow.

NACA TN 4361

IDEALIZED WINGS AND WING-BODIES AT A MACH NUMBER OF 3. Elliott D. Katzen. July 1958. 11p. diagrs. (NACA TN 4361)

Calculations indicate the possibility of obtaining high lift-drag ratios at a Mach number of 3, and some experiments which were designed to exploit the theory are described. The relatively high lift-drag ratios calculated were partly realized. A trimmed lift-drag ratio of 9 was obtained, instead of the estimated value of 11, at the maximum test Reynolds number of 3.5 million (based on wing mean aerodynamic chord).

THE ICING OF COMPRESSOR BLADES AND THEIR PROTECTION BY SURFACE HEATING. G. L. Shires and G. E. Munns. 1958. 41p. diagrs., photos., tabs. ARC R & M 3041; ARC 18,246 Supersedes NGTE Report R. 178.
(Ask for N-40490X*)

Experiments with surface-heated inlet guide vanes and stator blades were performed in the icing tunnel at the RAE. An electrically heated blade, having almost uniform surface temperature, was developed and then used to determine the effects of air velocity and icing conditions on the minimum heat flow required to prevent the formation of ice. The theoretical method, by J. K. Hardy, of calculating this heat requirement shows reasonable agreement with the

*AVAILABLE ON LOAN ONLY.

BRITISH REPORTS

experimental results. Steel, copper, and copper-plated gas-heated blades with various internal passage shapes were also tested and their heat requirement compared with those of the corresponding electrically heated blades under the same external conditions. Finally, a method of estimating the pressure drop through the gas-heated blades is suggested.

THE INFLUENCE OF PLAIN BEARINGS ON SHAFT WHIRLING. E. Downham. 1958. 25p. diagrs., photo., tabs. ARC R & M 3046; ARC 18,523. Supersedes RAE Report Structures 192. (Ask for N-42468X*)

Experiments are described which show the effects of bearing length, bearing clearance, and lubricant viscosity on the critical whirling speeds of a single-shaft rotor system supported in plain bearings. The critical speed of a two-bearing-shaft rotor system is shown to depend upon rotor unbalance for bearings of normal clearance. When the clearance is small relative to the bearing length, unsymmetric stiffness characteristics are obtained and produce two critical speeds instead of one. The lubricant in a drip-feed bearing is shown to have a stiffening effect, with consequent increase of critical whirling speed. It is also shown that the critical whirl amplitudes with dry bearings can be appreciably larger than those obtained with lubricated bearings.

MEASUREMENT OF THE SOUND FROM CIRCULAR CYLINDERS IN AN AIR STREAM. J. H. Gerrard, University of Manchester. June 30, 1955. 14p. diagrs. ARC 17,725; FM 2271. (Ask for N-62503*)

The frequency and intensity of the sound produced by flow past circular cylinders were investigated experimentally in the range of RN in which a periodic shedding of vortices occurs. The cylinders were placed in a wind tunnel or on a whirling device. The sound resulting from the production of a vortex street was found to possess a dipole field which consisted of a predominant fundamental frequency accompanied by harmonics. The investigation was confined to the examination of the intensity and frequency of the fundamental. When this frequency was expressed as a Strouhal number agreement was obtained between the acoustic frequency and that found, by other workers, in the wake itself. The sound intensity was found to vary with RN in a similar way to the pressure coefficient at the rear of the cylinder.

THE THEORY OF A THIN, SLENDER, CONICAL WING WITH THE WING BOUNDARY CONDITION APPLIED AT ITS SURFACE. J. H. B. Smith. March 1958. 31p. diagrs. RAE Report Aero 2602. (Ask for N-62510*)

Slender wing theory is used to calculate the lift and drag forces acting on a thin slender delta wing cambered to form part of the surface of a circular cone, in the type of flow in which separation is from the trailing edge only. The boundary condition satisfied by the flow on the wing surface is applied there, instead of on a nearby plane as is usual in linearized theory. This has relatively little effect on the overall forces on a wing at a given incidence. However, a large discrepancy arises between the overall forces at the incidence for which the singularity in the pressure at the leading edge vanishes, as calculated by the present and by the usual linearized theory. This is particularly important, since it is at this incidence that the type of flow treated is expected to be realized in a physical fluid. The lift-dependent drag factor found is below the usual linearized theory value for this type of wing at the incidence of no leading-edge singularity and, for large lift, is below unity, which is the minimum for a trailing vortex sheet which is effectively flat.

Aeronautical Research Council (Gt. Brit.)
A RAPIDLY CONVERGENT PROCESS FOR SOLVING THE EQUATIONS OF SUBSONIC FLOW. II. ANALYTIC SOLUTIONS IN TWO DIMENSIONS. A. B. Tayler, Mathematical Institute, Oxford. March 28, 1958. 23p. diagrs. ARC 20,028; FM 2573a. (Ask for N-62512*)

This is a continuation of ARC 19,470 which obtained a second approximation to the subsonic flow of an irrotational inviscid fluid. Results were obtained numerically for a circular cylinder with $M_\infty = 0.4$, and were shown to have an error of less than 1 percent. In this paper an analytic solution of the second approximation equations is obtained, valid for all two-dimensional shapes whose conformal transformation into a circle is known. Results are obtained for the circular cylinder at $M_\infty = 0.4$ and compared with those obtained numerically. Also results are obtained for Kaplan's airfoil and a circular cylinder with circulation.

NACA RM A50A03

WIND-TUNNEL TESTS OF A 0.16-SCALE MODEL OF THE X-3 AIRPLANE AT HIGH SUBSONIC SPEEDS. STABILITY AND CONTROL CHARACTERISTICS. William T. Hamilton and Joseph W. Cleary. April 21, 1950. 129p. diagrs., photos., tabs. (NACA RM A50A03)

Wind-tunnel tests of the 0.16-scale X-3 model were made at low and high subsonic Mach numbers to investigate the static longitudinal and lateral stability characteristics. The tests showed that undesirable changes in longitudinal stability at the stall were apparently caused by an altered downwash pattern at the tail. The jettisonable nose fins were highly destabilizing. Compressibility effects for the test Mach numbers were not detrimental to the longitudinal or lateral stability characteristics.

NACA RM A51F12

WIND-TUNNEL TESTS OF A 1/12-SCALE MODEL OF THE X-3 AIRPLANE AT SUBSONIC AND SUPERSONIC SPEEDS. Robert N. Olson and Robert S. Chubb. September 14, 1951. 111p. diagrs., photo., tabs. (NACA RM A51F12)

The static longitudinal, lateral, and directional stability and control characteristics of a 1/12-scale model of the Douglas X-3 airplane at subsonic and supersonic Mach numbers are presented. The model was equipped with an all-movable horizontal tail, an aileron on the left wing, and a rudder on the vertical-tail surface. The investigation covered a range of Mach numbers from 0.60 to 0.93 and 1.30 to 1.91 at Reynolds numbers of 0.98 to 2.61 million.

NACA RM A53G22

CORRELATION OF FLIGHT AND WIND-TUNNEL MEASUREMENTS OF ROLL-OFF IN LOW-SPEED STALLS ON A 35° SWEPT-WING AIRCRAFT. Seth B. Anderson. September 1953. 17p. diagrs., photos., tabs. (NACA RM A53G22)

Flight and full-scale wind-tunnel measurements were made of the low-speed stalling characteristics to correlate pilot opinion with quantitative measurements. Included in this study are the effects on the stalling characteristics of a number of wing modifications.

NACA RM A55G19

A STUDY OF CONICAL CAMBER FOR TRIANGULAR AND SWEPTBACK WINGS. John W. Boyd, Eugene Migotsky, and Benton E. Wetzel. November 1955. 79p. diagrs., tabs. (NACA RM A55G19)

A theoretical and experimental study has been made to determine the effectiveness of conical camber in reducing the drag due to lift of low-aspect-ratio triangular and sweptback wings. The wings investigated were derived by lifting-surface theory. Design charts for determination of the shape of the cambered surface are included. Experimental data obtained for an aspect-ratio-2 triangular wing and a 45° sweptback wing of aspect ratio 3 for Mach numbers from 0.22 to 1.90 are presented as a measure of the adequacy of the theory.

NACA RM A56H30

AN ANALOG COMPUTER STUDY OF SEVERAL STABILITY AUGMENTATION SCHEMES DESIGNED TO ALLEVIATE ROLL-INDUCED INSTABILITY. Brent Y. Creer. February 1957. 50p. diagrs., tab. (NACA RM A56H30)

In the analog computer study the stability augmentors considered were a roll-rate limiter, a sideslip limiter, an augmentor employing feedback proportional to the product of rolling velocity and pitching velocity, and combinations of the roll-rate limiter with each of the other two. The influence of changes in the system feedback characteristics on the airplane rolling motions was investigated for five different flight conditions. In each case, the motions of the augmented airplane are compared with those of the unaugmented airplane.

NACA RM E50J26

FORCE AND PRESSURE CHARACTERISTICS FOR A SERIES OF NOSE INLETS AT MACH NUMBERS FROM 1.59 TO 1.99. I - CONICAL SPIKE ALL-EXTERNAL COMPRESSION INLET WITH SUBSONIC COWL LIP. Fred T. Esenwein and Alfred S. Valerino. January 19, 1951. 73p. diagrs., photos., tabs. (NACA RM E50J26)

An experimental investigation to determine force and pressure characteristics of conical-spike all-external compression nose inlet with subsonic cowl lip was conducted over range of mass flows and angles of attack from 0° to 10° at Mach numbers 1.59 to 1.99. The Reynolds number, based on inlet diameter, was approximately 2.13×10^6. Internal-flow and pressure-recovery characteristics are included. Breakdown of measured drag coefficients at zero angle of attack into pressure, friction, and additive drag indicated that increase in drag with decreasing mass flow resulted from large increase in additive drag. Friction- and additive-drag coefficients closely agreed with calculated values; pressure drag was predicted for zero mass spillage only.

NACA RM E50J26a

FORCE AND PRESSURE CHARACTERISTICS FOR A SERIES OF NOSE INLETS AT MACH NUMBERS FROM 1.59 TO 1.99. II - ISENTROPIC-SPIKE ALL-EXTERNAL COMPRESSION INLET. L. J. Obery and G. W. Englert. February 9, 1951. 67p. diagrs., photos., tabs. (NACA RM E50J26a)

Internal- and external-flow characteristics of external-compression-type ram-jet-inlet configuration utilizing isentropic spike are presented for range of mass-flow ratios and angles of attack at Mach numbers 1.59, 1.79, and 1.99. Force and pressure measurements were made on configuration and comparison

DECLASSIFIED NACA RESEARCH REPORTS

of experimental results with theory is made when possible. At zero angle of attack, additive and skin-friction drags were predicted reasonably well for all conditions and extrapolation of experimental data indicated that pressure drag would be accurately predicted at mass-flow ratio of unity. Lift and pitching moment agreed closely with theoretical values. Shock oscillation occurred at high Mach numbers and increased in severity with angle of attack and Mach number.

NACA RM E50J30

FORCE AND PRESSURE CHARACTERISTICS FOR A SERIES OF NOSE INLETS AT MACH NUMBERS FROM 1.59 TO 1.99. III - CONICAL-SPIKE ALL-EXTERNAL-COMPRESSION INLET WITH SUPERSONIC COWL LIP. Maynard I. Weinstein and Joseph Davids. February 14, 1951. 51p. diagrs., tabs. (NACA RM E50J30)

Force and pressure characteristics of an all-external-compression inlet having a supersonic cowl lip were experimentally investigated at Mach numbers 1.59, 1.79, and 1.99 for a range of mass flows and at angles of attack to 10°. The Reynolds number based on inlet diameter was 2.3×10^{6}. Analysis of drag components indicated that rapid increase of total drag with decreasing mass flow was due to increase of additive drag. At zero angle of attack, adequate theoretical predictions were made of additive drag, friction drag, and at shock swallowed conditions, of pressure drag. Total-pressure recovery was in general only slightly reduced by increases in angle of attack to 10°.

NACA RM E51B05

FORCE AND PRESSURE CHARACTERISTICS FOR A SERIES OF NOSE INLETS AT MACH NUMBERS FROM 1.59 TO 1.99. IV - CONICAL-SPIKE EXTERNAL-INTERNAL COMPRESSION INLET UTILIZING PERFORATED COWL. Robert T. Madden and Emil J. Kremzier. March 28, 1951. 46p. diagrs., photos., tabs. (NACA RM E51B05)

Investigation to determine force and pressure characteristics of conical-spike external-internal compression nose inlet utilizing perforated cowl was conducted over range of mass flows and angles of attack from 0° to 10° at Mach numbers of 1.59, 1.79, and 1.99. The Reynolds number based on inlet diameter was approximately 2.4×10^{6}. Use of a perforated cowl resulted in attainment of high pressure recoveries but was accompanied by relatively large increase in external drag as compared with nonperforated inlets. Range of shock oscillation encountered at lower mass-flow ratios increased with angle of attack. Subsonic-flow coefficient for perforations was 0.53.

NACA RM E52L23

FUNDAMENTAL FLAME VELOCITY, HEAT OF COMBUSTION, AND SPONTANEOUS IGNITION TEMPERATURE OF DIMETHYLAMINODIBORANE. Robert R. Hibbard and Gordon L. Dugger. December 1956. 6p. diagr., tab. (NACA RM E52L23)

The following properties have been determined for a sample of dimethylaminodiborane: (1) maximum fundamental flame velocity for fuel and air at 35° C, 115 ± 5 centimeters per second; (2) net (lower) heat of combustion of liquid fuel to gaseous nitrogen, carbon dioxide, and water, and to solid boric oxide, 19,225 ± 100 Btu per pound; and (3) spontaneous ignition temperature, 240° ± 10° F.

NACA RM E53E11

THE HEAT OF COMBUSTION OF TETRAETHYLDIBORANE. Stanley Tannenbaum. January 1957. 5p. tabs. (NACA RM E53E11)

The net heat of combustion of a sample of tetraethyldiborane was found to be 20,400 ± 130 Btu per pound for the reaction of liquid fuel to gaseous carbon dioxide, gaseous water, and solid boric oxide. The measurements were made in a Parr oxygen bomb calorimeter and the combustion is believed to have been 99 percent complete. A more reasonable value for the net heat of combustion would therefore be 20,600 ± 130 Btu per pound.

NACA RM E53G15

ALUMINUM BOROHYDRIDE AS AN IGNITION SOURCE FOR TURBOJET COMBUSTORS. David M. Straight, Edward A. Fletcher, and Hampton H. Foster. September 1953. 19p. diagrs., photos., tabs. (NACA RM E53G15)

An investigation was conducted to determine the feasibility of using aluminum borohydride as an ignition source in a single tubular turbojet-engine combustor. For combustor air-flow rates from 1.87 to 6.0 pounds per second per square foot, altitude pressures which limited ignition with aluminum borohydride (single injections of 1 to 2 cc) were about 2 inches of mercury lower than those obtained for a high-energy spark ignition system of 10 joules, 8 sparks per second. At a combustor-inlet pressure of 0.5 atmosphere, the air-velocity ignition limits with aluminum borohydride were about 25 percent greater than those with the 10-joule spark system and about double those with a 0.3-joule spark system. Static chamber tests indicated that mixtures with n-pentane containing as little as 20 mole percent aluminum borohydride were spontaneously flammable at pressure conditions more severe than those encountered in turbojet-engine operation. Aluminum borohydride appears to be an excellent ignition source for turbojet combustors. However, there remain problems of storing this chemical and the development of a suitable means of injecting the chemical into the combustor. Further work aimed at the solution of these problems for either aluminum borohydride or another igniter fluid is considered warranted.

#NACA RM SE53G22, by Hatch and Lucas.

NACA RM E54G20

INVESTIGATION OF THREE HIGHLY LOADED SUBSONIC-INLET-STAGE AXIAL-FLOW COMPRESSORS EMPLOYING VARYING RADIAL GRADIENTS OF ENERGY ADDITION. Raymond M. Standahar. October 1954. 33p. diagrs., photos., tabs. (NACA RM E54G20)

Three experimental inlet-type axial-flow compressor stages were investigated to determine whether high pressure ratios can be obtained by means of high turning with highly cambered subsonic types of blading, and to determine the effectiveness of radial gradients of energy addition in reducing the deceleration across the rotor tip and thus relieving the effect of high tip loading. Efficiencies and pressure ratios ranged from 0.66 to 0.90, and 1.35 to 1.40, respectively. The rotor tip section for each design was in a state of stall at all times. Although the overall integrated results of two designs appeared good, the outlet-flow distribution would make staging of these designs very difficult.

NACA RM E55A27

DESIGN AND PERFORMANCE OF A 1400-FOOT-PER-SECOND-TIP-SPEED SUPERSONIC COMPRESSOR ROTOR. John F. Klapproth, John J. Jacklitch, Jr., and Edward R. Tysl. April 1955. 48p. diagrs., photo., tab. (NACA RM E55A27)

A supersonic compressor with a 1400 ft/sec tip speed was designed by a channel-flow method to have the same static-pressure recovery (that is, the ratio of static-pressure rise to inlet dynamic head of each blade row) in the rotor and the stator. The rotor performance results at design speed gave a total-pressure ratio of 2.17, an adiabatic efficiency of 89 percent, and a weight flow of 28 lb/sec. Maximum efficiency of 94 percent was obtained at a design speed of 82 percent and a total-pressure ratio of 1.65. For inlet relative Mach numbers up to 1.35, the blade-element losses are shown to be comparable with the losses in subsonic and transonic compressors operating at equivalent values of blade loading.

NACA RM E55C23

ANALYTICAL AND EXPERIMENTAL STUDY OF TRANSIENT-RESPONSE CHARACTERISTICS OF A TURBOPROP ENGINE. R. T. Craig, S. Nakanishi, and D. B. Wile. October 1955. 50p. diagrs., photo., tabs. (NACA RM E55C23)

Transient-response characteristics of a turboprop engine were studied over a range of Mach numbers from 0.15 to 0.5 at simulated altitudes of 15,000 and 35,000 feet. Generalized engine response was found to be dependent on power level and flight condition. Engine response to propeller-blade-angle disturbances was essentially first order and linear, while response to fuel-flow disturbances was of different form. Accurate prediction of engine transient performance from steady-state maps was found to be possible only when steady-state data are available for each flight condition considered.

NACA RM E55G14

ANALYTICAL COMPARISON OF CONVECTION-COOLED TURBINE BLADE COOLING-AIR REQUIREMENTS FOR SEVERAL RADIAL GAS-TEMPERATURE PROFILES. James E. Hubbartt and Henry O. Slone. September 1955. 46p. diagrs. (NACA RM E55G14)

Cooling-air requirements determined for several combustor-outlet radial gas-temperature profiles are compared, with the uniform profile as a basis. Profiles represented by complete and half-cycle cosine waves permit good combustor performance while generally decreasing the turbine casing cooling problem. For design conditions of immediate interest (turbine-inlet temperatures near 2600° R, blade root stresses of 25,000 psi, and flight Mach numbers near 2.0), the turbine rotor cooling-air requirements are slightly higher than those of the uniform profile. At the same conditions, the profile corresponding to the absolute minimum cooling-air flow presents severe stator inner-ring cooling problems with a saving in coolant flow of about 20 percent.

NACA RM E55G26

CALCULATED HEATS OF FORMATION AND COMBUSTION OF BORON COMPOUNDS (BORON, HYDROGEN, CARBON, SILICON). Aubrey P. Altshuller. October 1955. 28p. diagrs., tabs. (NACA RM E55G26)

The heats of formation and combustion for liquid and gaseous alkyl- and silyl-substituted boron hydrides have been calculated by a semitheoretical method. The effects of substitution of alkyl or silyl groups in decreasing the heats of combustion of boron hydrides are discussed in detail. The heats of combustion can be obtained with uncertainties of about 1 or 2 percent.

NACA RM E56G13

THERMODYNAMIC STUDY OF AIR-CYCLE AND MERCURY-VAPOR-CYCLE SYSTEMS FOR REFRIGERATING COOLING AIR FOR TURBINES OR OTHER COMPONENTS. Alfred J. Nachtigall, John C. Freche, and Jack B. Esgar. October 1956. 47p. diagrs. (NACA RM E56G13)

An analysis of air refrigeration systems indicated that air cycles are generally less satisfactory than simple heat exchangers unless high component efficiencies and high values of heat-exchanger effectiveness can be obtained. A system employing a mercury-vapor cycle appears to be feasible for refrigerating air that must enter the system at temperature levels of approximately 1500° R, and this cycle is more efficient than the air cycle. Weight of the systems was not considered. The analysis of the systems is presented in a generalized dimensionless form.

UNAVAILABLE; contains proprietary or obsolete information.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E56G20

EFFECT OF SEVERAL DESIGN VARIABLES ON INTERNAL PERFORMANCE OF CONVERGENT-PLUG EXHAUST NOZZLES. H. George Krull, William T. Beale, and Ralph F. Schmiedlin. October 1956. 33p. diagrs., photos., tab. (NACA RM E56G20)

Numerous experiments were conducted to determine factors which affect the internal performance of convergent-plug exhaust nozzles. The results of these experiments, which include effects of such things as plug shape, nozzle inlet Mach number, and outer-shell characteristics, provide a basis for optimum design from the standpoint of weight and size. The results also show performance penalties which can result when the nozzle is too small.

NACA RM E56G26

EFFECT OF FUSELAGE CIRCUMFERENTIAL INLET LOCATION ON DIFFUSER-DISCHARGE TOTAL-PRESSURE PROFILES AT SUPERSONIC SPEEDS. Emil J. Kremzier and Joseph F. Wasserbauer. October 1956. 14p. diagrs. (NACA RM E56G26)

An experimental investigation of the effect of angle of attack and inlet corrected air flow on diffuser-discharge total-pressure profiles of inlets located in various circumferential positions on a fuselage was conducted at supersonic speeds. Results indicated that the diffuser total-pressure profiles for a bottom inlet were least affected by angle of attack. The largest effect of angle of attack on distortion level was obtained with a side inlet. Variation in distortion for top inlets with angle of attack was confined to the supercritical range of inlet operation.

NACA RM E58B11 out to Sibley

EFFECT OF SLIDING VELOCITY ON FRICTION PROPERTIES AND ENDURANCE LIFE OF BONDED LEAD MONOXIDE COATINGS AT TEMPERATURES UP TO 1250° F. Harold E. Sliney. May 1958. 15p. diagrs. (NACA RM E58B11)

Thin lead monoxide coatings bonded to type 440-C stainless steel were evaluated at sliding velocities from 6 to 10,000 ft/min over a temperature range of 75° to 1250° F. Friction decreased when either ambient temperature or sliding velocity was increased. For sliding velocities of 350 and 2400 ft/min, endurance life increased with increasing temperature up to a maximum at approximately 1000° F.

NACA RM H54I17

LIFT AND DRAG CHARACTERISTICS OF THE DOUGLAS X-3 RESEARCH AIRPLANE OBTAINED DURING DEMONSTRATION FLIGHTS TO A MACH NUMBER OF 1.20. Donald R. Bellman and Edward D. Murphy. December 1954. 23p. diagrs., photos., tab. (NACA RM H54I17)

Lift and drag data for the Douglas X-3 airplane were obtained during some of the demonstration flights. The data extend over the Mach number range from 0.82 to 1.20 and for certain constant Mach numbers the lift coefficient range from 0 to 1.0 is covered. A comparison of the flight data with wind-tunnel and rocket-model tests shows that the model tests satisfactorily predict the performance of the airplane.

NACA RM H54K24

National Advisory Committee for Aeronautics. RESULTS OF MEASUREMENTS MADE DURING THE APPROACH AND LANDING OF SEVEN HIGH-SPEED RESEARCH AIRPLANES. Wendell H. Stillwell. February 1955. 25p. diagrs., tab. (NACA RM H54K24)

Measurements made during the approach and landing of the X-1, X-3, X-4, X-5, D-558-I, D-558-II, and XF-92A research airplanes are presented. Data are also presented for the effect of lift-drag ratio on the landing characteristics of the X-4 airplane.

NACA RM H55A10

PRELIMINARY FLIGHT-DETERMINED PRESSURE DISTRIBUTIONS OVER THE WING OF THE DOUGLAS X-3 RESEARCH AIRPLANE AT SUBSONIC AND TRANSONIC MACH NUMBERS. Gareth H. Jordan and C. Kenneth Hutchins, Jr. April 1955. 34p. diagrs., photos., tabs. (NACA RM H55A10)

Presented are preliminary flight-measured chordwise pressure distributions obtained at a midsemispan station on the wing of the Douglas X-3 research airplane through an angle-of-attack range at Mach numbers of approximately 0.61, 0.78, 0.94, and 1.10.

NACA RM H55A13

FLIGHT EXPERIENCE WITH TWO HIGH-SPEED AIRPLANES HAVING VIOLENT LATERAL-LONGITUDINAL COUPLING IN AILERON ROLLS. NACA High-Speed Flight Station. February 1955. 30p. diagrs., photos., tabs. (NACA RM H55A13)

During flight tests of two high-speed airplane configurations violent cross-coupled lateral and longitudinal motions were encountered following abrupt rudder-fixed aileron rolls at Mach numbers between 0.7 and 1.05.

NACA RM H55E16

STABILITY AND CONTROL CHARACTERISTICS OBTAINED DURING DEMONSTRATION OF THE DOUGLAS X-3 RESEARCH AIRPLANE. Richard E. Day and Jack Fischel. July 1955. 51p. diagrs., photos., tab. (NACA RM H55E16)

Results obtained from flights of the manufacturer's demonstration program and from U. S. Air Force evaluation flights of the Douglas X-3 research airplane are presented. Data evaluation includes static longitudinal, directional, and lateral stability and control for Mach numbers up to 1.21 at pressure altitudes from 12,800 feet to 34,000 feet. Comparisons are made with wind-tunnel and rocket-model tests.

NACA RM H55E17b

FLIGHT EXPERIENCE OF INERTIA COUPLING IN ROLLING MANEUVERS. Joseph Weil, Ordway B. Gates, Jr., Richard D. Banner, and Albert E. Kuhl. July 1955. 12p. diagrs. (NACA RM H55E17b)

A brief discussion is presented of the flight tests of two airplanes which have exhibited strong coupling between their lateral and longitudinal motions. Results are presented which indicate the effect of directional stability and vertical tail size on the tail shear loads encountered in rolling maneuvers.

NACA RM H55G07

WING PRESSURE DISTRIBUTIONS OVER THE LIFT RANGE OF THE CONVAIR XF-92A DELTA-WING AIRPLANE AT SUBSONIC AND TRANSONIC SPEEDS. Earl R. Keener and Gareth H. Jordan. November 1955. 135p. diagrs., photos., tabs. (NACA RM H55G07)

Chordwise and spanwise pressure distributions are presented for the left wing of the Convair XF-92A delta-wing airplane at Mach numbers from 0.30 to 0.93. Reynolds number based on the mean aerodynamic chord of the wing varied between 22×10^6 and 49×10^6. The data cover the lift range from level flight to near-maximum lift. Effects of wing-section stall upon the elevon-section loads are included.

NACA RM H55G26

FLIGHT MEASUREMENTS OF DIRECTIONAL STABILITY TO A MACH NUMBER OF 1.48 FOR AN AIRPLANE TESTED WITH THREE DIFFERENT VERTICAL TAIL CONFIGURATIONS. Hubert M. Drake, Thomas W. Finch, and James R. Peele. October 1955. 22p. diagrs., photos., tab. (NACA RM H55G26)

Directional stability characteristics have been determined from the measured period and damping of a fighter-type airplane over the Mach number range from 0.72 to 1.48 at altitudes of 40,000 feet and 30,000 feet. Three different vertical tails of varying aspect ratio or area, or both, were employed.

NACA RM H56A23

FLIGHT MEASUREMENTS OF HORIZONTAL-TAIL LOADS ON THE DOUGLAS X-3 RESEARCH AIRPLANE. Harriet J. Stephenson. April 1956. 33p. diagrs., photo., tab. (NACA RM H56A23)

Horizontal-tail loads were obtained from strain-gage measurements during flight tests of the Douglas X-3 research airplane over a Mach number range of 0.65 to 1.16. The horizontal-tail-panel lift-curve slope was obtained from stabilizer pulses. Balancing-tail loads, downwash, and total airplane pitching moment were obtained from wind-up turns and pull-ups.

NACA RM H56G13

WING LOADS AND LOAD DISTRIBUTIONS THROUGHOUT THE LIFT RANGE OF THE DOUGLAS X-3 RESEARCH AIRPLANE AT TRANSONIC SPEEDS. Earl R. Keener and Gareth H. Jordan. November 1956. 191p. diagrs., photo., tabs. (NACA RM H56G13)

Wing loads and load distributions were obtained in flight by differential-pressure measurements between the upper and lower surfaces of the left wing of the Douglas X-3 research airplane. The effects of angle of attack and Mach number on the wing characteristics at transonic Mach numbers are shown. The wing has an aspect ratio of 3.09 and a modified 4.5-percent-thick hexagonal section. Data cover the range from near-zero lift to maximum lift, over a Mach number range of 0.71 to 1.15. Reynolds number based on the mean aerodynamic chord of the wing varied between 16×10^6 and 26×10^6.

NACA RM H56H08

ANALYSIS OF THE VERTICAL-TAIL LOADS MEASURED DURING A FLIGHT INVESTIGATION AT TRANSONIC SPEEDS OF THE DOUGLAS X-3 RESEARCH AIRPLANE. William L. Marcy, Harriet J. Stephenson, and Thomas V. Cooney. November 1956. 32p. diagrs., photo., tab. (NACA RM H56H08)

An analysis of the vertical-tail loads obtained from strain-gage measurements during a flight investigation of the Douglas X-3 research airplane in the transonic speed range is presented. Data from rudder pulses, gradually increasing sideslips, and rudder-fixed aileron rolls were used to obtain rudder effectiveness and the effective lift-curve slope of the vertical tail. The variation of airplane yawing-moment coefficient with sideslip as determined from the measured vertical-tail loads is also presented.

NACA RM H57H09

FLIGHT DATA PERTINENT TO BUFFETING AND MAXIMUM NORMAL-FORCE COEFFICIENT OF THE DOUGLAS X-3 RESEARCH AIRPLANE. Thomas F. Baker, James A. Martin, and Betty J. Scott. November 1957. 41p. diagrs., photo., tabs. (NACA RM H57H09)

The X-3 airplane, which has a straight, 4.5-percent-thick wing, was flown to maximum wing lift at Mach numbers from 0.7 to 1.1 at an average altitude of 30,000 feet. Airplane and wing maximum normal-force coefficients and buffeting characteristics were determined. Wing maximum normal-force coefficients at low supersonic speeds were almost twice the values at subsonic speed ($M \approx 0.8$). At transonic speeds the buffet boundary abruptly increased, rather than decreased, with Mach number. The buffeting encountered did not constitute either an operational or a structural problem. The effective longitudinal maneuverability limit was defined by maximum wing lift. Limited data at subsonic speeds on the effects on lift and buffeting of deflecting the wing leading-edge flaps 7° are included.

NACA RM H57I05

FLIGHT INVESTIGATION OF THE TRANSONIC LONGITUDINAL AND LATERAL HANDLING QUALITIES OF THE DOUGLAS X-3 RESEARCH AIRPLANE. Jack Fischel, Euclid C. Holleman, and Robert A. Tremant. December 1957. 61p. diagrs., photos., tab. (NACA RM H57I05)

A flight investigation was performed to determine the longitudinal and lateral handling qualities of the Douglas X-3 research airplane in the clean configuration and with wing leading-edge flaps deflected. Static and dynamic stability and control characteristics were determined during trimmed and maneuvering flight at an average altitude of 30,000 feet over a Mach number range from 0.7 to 1.16. Statically and dynamically determined stability and control derivatives are presented, as well as pilot evaluation of the airplane.

NACA RM H57L06

HIGH-SPEED LANDING LOADS MEASURED ON THE DOUGLAS X-3 RESEARCH AIRPLANE. William L. Marcy. February 1958. 24p. diagrs., photo., tabs. (NACA RM H57L06)

Measured loads are shown for several landings of the Douglas X-3 at speeds from about 310 to 420 feet per second. Sinking speeds were between 2 and 5 feet per second. Some loads during taxiing and turning are also shown.

NACA RM L51G10

AN INVESTIGATION OF THE LONGITUDINAL CHARACTERISTICS OF THE X-3 CONFIGURATION WITH WING AND HORIZONTAL TAIL SURFACES OF ASPECT RATIO 3.0 BY MEANS OF ROCKET-PROPELLED MODELS. RESULTS AT HIGH LIFT COEFFICIENTS. Robert F. Peck and Jesse L. Mitchell. August 27, 1951. 34p. diagrs., photos. (NACA RM L51G10)

A rocket-propelled model of the X-3 configuration equipped with an all-movable tail of aspect ratio 3.0 has been flown, primarily to determine the longitudinal stability characteristics of this configuration at high lift coefficients.

NACA RM L51G12

DERIVATION OF THE EQUATIONS OF MOTION OF A SYMMETRICAL WING-TIP-COUPLED AIRPLANE CONFIGURATION WITH ROTATIONAL FREEDOM AT THE JUNCTURES. Albert A. Schy. October 1951. 45p. diagrs. (NACA RM L51G12)

The equations of motion are derived for a configuration consisting of a bomber and two identical fighters coupled wing tip to wing tip with complete rotational freedom at the coupling joints. It is shown how the equations may be simplified when one or two of the rotational degrees of freedom at the coupling joint are rigidly restrained. Although the equations are originally derived without considering aerodynamic interference between the airplanes, it is shown how these interference effects may be included when they are known.

NACA RM L51H08

A WIND-TUNNEL INVESTIGATION OF THE STATIC STABILITY CHARACTERISTICS OF A 1/8-SCALE EJECTABLE PILOT-SEAT COMBINATION AT A MACH NUMBER OF 0.8. Fioravante Visconti and Robert J. Nuber. December 1951. 29p. diagrs., photos. (NACA RM L51H08)

An investigation was made of a 1/8-scale model of an ejectable pilot-seat combination with and without stabilizing fins. The purpose of this investigation was to determine the static aerodynamic characteristics and the effectiveness of various stabilizing fins at a high subsonic Mach number.

NACA RM L51K12

FREE-SPINNING TUNNEL INVESTIGATION OF A 1/20-SCALE MODEL OF THE DOUGLAS X-3 AIRPLANE. Burton E. Hultz. December 26, 1951. 23p. diagrs., photos., tab. (NACA RM L51K12)

An investigation of the spin and recovery characteristics of a 1/20-scale model of the Douglas X-3 airplane has been conducted in the Langley 20-foot free-spinning tunnel. The results indicate that at spin test altitudes of 15,000 to 30,000 feet the airplane generally will not spin erect and should not exhibit any unusual trim conditions. At high altitudes, flat trimming tendencies appear possible on the airplane.

NACA RM L52A10a

THE STATIC AND DYNAMIC LONGITUDINAL STABILITY CHARACTERISTICS OF SOME SUPERSONIC AIRCRAFT CONFIGURATIONS. Jesse L. Mitchell. January 1952. 19p. diagrs. (NACA RM L52A10a)

The static and dynamic longitudinal stability characteristics of several supersonic aircraft configurations are discussed at both subsonic and supersonic speeds. The presentation includes the effect of horizontal-tail height on static stability, the effect of stability changes with Mach number on maneuverability and trim, the damping-in-pitch derivative for some tailless aircraft, and the period and damping characteristics of the short-period longitudinal oscillation.

NACA RM L52G02

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF NACELLE SHAPE AND POSITION ON THE AERODYNAMIC CHARACTERISTICS OF TWO 47° SWEPTBACK WING-BODY CONFIGURATIONS. Ralph P. Bielat and Daniel E. Harrison. September 1952. 87p. diagrs., photos., tab. (NACA RM L52G02)

An investigation has been made in the Langley 8-foot transonic tunnel to determine the effects of nacelle shape and position on the aerodynamic characteristics of two sweptback wing-body configurations. The two wings had 47° sweepback of the 0.25-chord line, aspect ratio of 3.5, taper ratio of 0.2, and zero twist and dihedral. Underslung, pylon-suspended, and wing-tip nacelles were investigated in conjunction with one of these wings which had 6-percent-thick sections along the span. Nacelles submerged in the wing root also were studied on this wing and on the second wing which had a root section that varied linearly in thickness ratio from 12 percent at the plane of symmetry to 6 percent at the 40-percent-semispan station. Lift, drag, and pitching-moment results are presented at Mach numbers varying from 0.50 to 1.12 and Reynolds numbers varying from 2.0×10^6 to 2.6×10^6 based on the wing mean aerodynamic chord.

NACA RM L52H01

AN INVESTIGATION OF A 0.16-SCALE MODEL OF THE DOUGLAS X-3 AIRPLANE TO DETERMINE MEANS OF IMPROVING THE LOW-SPEED LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS. John W. McKee and John M. Riebe. November 1952. 90p. diagrs., photos., tabs. (NACA RM L52H01)

Results and discussion are presented of an investigation made in the Langley 300 MPH 7- by 10-foot tunnel to determine means of improving the low-speed longitudinal stability and control characteristics of a 0.16-scale model of the Douglas X-3 airplane. Various high-lift devices in the form of plain and slotted leading-edge flaps and plain, split, and slotted trailing-edge flaps were also investigated on the model.

NACA RM L53F19a

A ROCKET-MODEL INVESTIGATION OF THE LONGITUDINAL STABILITY, LIFT, AND DRAG CHARACTERISTICS OF THE DOUGLAS X-3 CONFIGURATION WITH HORIZONTAL TAIL OF ASPECT RATIO 4.33. Robert F. Peck and James A. Hollinger. August 1953. 33p. diagrs., photos. (NACA RM L53F19a)

A rocket-propelled model of the Douglas X-3 airplane with an enlarged all-movable horizontal tail of aspect ratio 4.33 has been flown to determine its longitudinal stability, lift, and drag characteristics at transonic and supersonic speeds. Comparisons are made with corresponding data from rocket propelled models with tails of aspect ratio 3.0 and with data from the Ames 6- by 6-foot and Langley 7- by 10-foot wind tunnels. Data were also obtained on the drag of a model (with a body of revolution) having the same longitudinal distribution of cross-sectional area as the scale airplane model. The transonic drag rise from the two models shows agreement within approximately 10 percent.

NACA RM L53G07a

INVESTIGATION OF SPOILER AILERONS WITH AND WITHOUT A GAP BEHIND THE SPOILER ON A 45° SWEPTBACK WING-FUSELAGE COMBINATION AT MACH NUMBERS FROM 0.60 TO 1.03. F. E. West, Jr., William Solomon, and Edward M. Brummal. September 1953. 38p. diagrs. (NACA RM L53G07a)

An investigation was conducted with several 73 percent semispan inboard spoiler ailerons, projecting 4 percent of the local wing chord above the wing surface, located at the 70-percent chord line of a 45° sweptback wing-fuselage combination. The wing had an aspect ratio of 3.98, a taper ratio of 0.61, and NACA 65A006 airfoil sections parallel to the plane of symmetry. Six-component force data were obtained in the Langley 16-foot transonic tunnel at Mach numbers from 0.60 to 1.03, usually for angles of attack from -2° to 20° or higher. Upper-surface-spoiler configurations with a gap in the wing behind the spoiler retained at least a small amount of rolling-moment effectiveness even at high angles of attack for the entire transonic speed range, whereas an upper-surface-spoiler configuration without a gap lost complete effectiveness at high angles of attack for most Mach numbers. A lower-surface-spoiler configuration also lost effectiveness at high angles of attack. The effect of the width of the gap behind the upper-surface spoiler on rolling-moment effectiveness is discussed.

NACA RM L53G17

THEORETICAL CALCULATIONS OF THE STABILITY DERIVATIVES AT SUPERSONIC SPEEDS FOR A HIGH-SPEED AIRPLANE CONFIGURATION. Kenneth Margolis and Percy J. Bobbitt. October 1953. 59p. diagrs., tab. (NACA RM L53G17)

Theoretical calculations of the stability derivatives at supersonic speeds for a high-speed airplane configuration are presented. The methods discussed represent detailed consideration of the important effects and contributions of the various airplane

DECLASSIFIED NACA RESEARCH REPORTS

components utilizing available theories and theoretically justifiable and reasonable approximations. Results of the analyses which are valid for motions involving small angles of attack and sideslip and low rates of rolling, pitching, and yawing, are presented in the form of graphs illustrating the variation of the stability derivatives with Mach number.

NACA RM L53G22a

LONGITUDINAL STABILITY CHARACTERISTICS AT TRANSONIC SPEEDS OF A ROCKET-PROPELLED MODEL OF AN AIRPLANE CONFIGURATION HAVING A 45° SWEPT WING OF ASPECT RATIO 6.0. John C. McFall, Jr. January 1954. 34p. diagrs., photos. (NACA RM L53G22a)

A flight investigation was conducted on a rocket-propelled airplane model having a 45° swept wing of aspect ratio 6.0, taper ratio 0.6, and NACA 65A009 airfoil section. The configuration had a swept empennage with a low tail position. Longitudinal stability and drag characteristics were determined over a Mach number range of 0.69 to 1.21.

NACA RM L53G31a

SUBSONIC AND SUPERSONIC HINGE-MOMENT AND EFFECTIVENESS CHARACTERISTICS OF AN UNBALANCED LATERAL CONTROL HAVING LOW THEORETICAL HINGE MOMENTS AT SUPERSONIC SPEEDS. Kennith L. Goin and William E. Palmer. October 1953. 55p. diagrs., photos. (NACA RM L53G31a)

Tests were made to determine the hinge-moment and effectiveness characteristics of an inversely tapered 60° half-delta control located at the tip of a clipped 60° delta wing. Tests were made at subsonic Mach numbers of 0.15 to 0.92 and at supersonic Mach numbers of 1.41, 1.62, and 1.96. Tests at subsonic Mach numbers were made at Reynolds numbers of 3.8×10^6 to 9×10^6 and tests at supersonic Mach numbers were made at Reynolds numbers of 2.2×10^6 to 3.3×10^6.

NACA RM L54G12a

EFFECTS OF OVERHANG BALANCE ON THE HINGE-MOMENT AND EFFECTIVENESS CHARACTERISTICS OF AN UNSWEPT TRAILING-EDGE CONTROL ON A 60° DELTA WING AT TRANSONIC AND SUPERSONIC SPEEDS. Lawrence D. Guy. September 1954. 48p. diagrs., photo. (NACA RM L54G12a)

A wind-tunnel investigation has been made of two unswept, partial-span, flap-type controls (differing only in hinge-line location) mounted on a 60° delta wing. One control was unbalanced and the other had a 100-percent overhang balance. Control hinge moments as well as aerodynamic characteristics of the complete wing-body combination were obtained for control deflections from 0° to 40° over an angle-of-attack range of ±12° at Mach numbers from 0.75 to 1.96. Reynolds numbers varied between 2.2×10^6 and 3.2×10^6. Expressions derived from linear theory for the hinge-moment coefficient due to angle of attack for unswept, partial-span controls (which extend neither to the wing tip nor to the wing center line) on triangular wings having subsonic leading edges are given in an appendix.

NACA RM L54G14

FLIGHT MEASUREMENTS OF AVERAGE SKIN-FRICTION COEFFICIENTS ON A PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT MACH NUMBERS FROM 1.0 TO 3.7. J. Dan Loposer and Charles B. Rumsey. August 1954. 32p. diagrs., photos. (NACA RM L54G14)

Average skin-friction coefficients for a slender parabolic body of revolution (NACA RM-10) were obtained from boundary-layer measurements in flight at Mach numbers from 1.0 to 3.7 and Reynolds numbers from 40×10^6 to 170×10^6 and over a wide range of wall heating conditions. A comparison is made with wind-tunnel measurements of skin friction on the NACA RM-10 body, and with theoretical turbulent skin-friction coefficients for a flat plate with heat transfer. An empirical equation representing the data over the test range is also presented.

NACA RM L54G20

AERODYNAMIC CHARACTERISTICS AT A MACH NUMBER OF 2.01 OF TWO CRUCIFORM MISSILE CONFIGURATIONS HAVING 70° DELTA WINGS WITH LENGTH-DIAMETER RATIOS OF 14.8 AND 17.7 WITH SEVERAL CANARD CONTROLS. M. Leroy Spearman and Ross B. Robinson. August 1954. 32p. diagrs., tabs. (NACA RM L54G20)

An investigation has been made in the Langley 4- by 4-foot supersonic pressure tunnel to determine the aerodynamic characteristics at a Mach number of 2.01 of two cruciform 70° delta-wing missile configurations having length-diameter ratios of 14.8 and 17.7 with several different canard-control surfaces. The complete model and various combinations of component parts were tested through an angle-of-attack range from 0° to about 28° and an angle-of-sideslip range from 0° to about -10°.

NACA RM L54G23a

STABILITY AND DRAG CHARACTERISTICS AT MACH NUMBERS FROM 0.8 TO 1.5 OF A FREE-FLIGHT MODEL HAVING 3-PERCENT-THICK, 60° TRIANGULAR WING AND HORIZONTAL TAIL SURFACES. Rowe Chapman, Jr., and Harvey A. Wallskog. August 1954. 30p. diagrs., photos., tab. (NACA RM L54G23a)

A flight test of a rocket-propelled model having 60° triangular wing and horizontal tail surfaces 3-percent thick was made to investigate the stability and drag of the configuration. Drag and stability data are compared with similar triangular-wing configurations.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L54G27a

AERODYNAMIC CHARACTERISTICS AT TRANSONIC AND SUPERSONIC SPEEDS OF A ROCKET-PROPELLED AIRPLANE CONFIGURATION HAVING A DIAMOND-PLAN-FORM WING OF ASPECT RATIO 3.08 AND A LOW, SWEPT HORIZONTAL TAIL. Alan B. Kehlet. September 1954. 37p. diagrs., photos. (NACA RM L54G27a)

A flight investigation was conducted on a rocket-propelled airplane configuration having a diamond-plan-form wing of aspect ratio 3.08 and NACA 65A003 airfoil sections in the streamwise direction. The configuration had a swept empennage with a horizontal tail of 45° quarter-chord-line sweep mounted in a low position. Characteristics of trim, drag, damping, and longitudinal and directional stability are presented over a Mach number range of 0.95 to 1.79. Also presented are comparisons on the effects of wing plan form between the diamond wing and a delta wing of 52.5° leading-edge sweep and 3.08 aspect ratio.

NACA RM L54G28

INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS AT HIGH SUPERSONIC MACH NUMBERS OF A FAMILY OF DELTA WINGS HAVING DOUBLE-WEDGE SECTIONS WITH THE MAXIMUM THICKNESS AT 0.18 CHORD. Mitchel H. Bertram and William D. McCauley. October 1954. 54p. diagrs., photos., tabs. (NACA RM L54G28)

The aerodynamic characteristics of a family of blunt double-wedge-section delta wings have been investigated at the Langley 11-inch hypersonic tunnel. These wings had a maximum thickness of 8 percent located at the 18-percent-chord point. For the wings tested at a Mach number of 6.9, the semiapex angle was varied from 30° to 5° and the wings were tested over a range of angle of attack from 0° to 28° and Reynolds numbers from 0.8×10^6 to 3.6×10^6 based on root chord. Pertinent results from tests at Mach numbers as low as 1.6 have been utilized. The shock-expansion and Newtonian impact theories have been used to analyze the effects of changes made in the various parameters investigated.

NACA RM L54G28a

FREE-FLIGHT DETERMINATION OF FORCE AND STABILITY CHARACTERISTICS OF AN INCLINED BODY OF FINENESS RATIO 16.9 AT A MACH NUMBER OF 1.74. Warren Gillespie, Jr. November 1954. 17p. diagrs., photos., tab. (NACA RM L54G28a)

Force and stability characteristics were obtained in free flight from a body of fineness ratio 16.9 of a Mach number of 1.74 and a Reynolds number of 94×10^6. The test results compare favorably with a wind-tunnel test of a similar body tested at a Mach number of 1.79 and with calculations by the method of Allen (NACA RM A9I26) for estimating the effects of viscosity on an inclined body of revolution. When the boundary layer is turbulent and the crossflow drag coefficient corresponding to a yawed circular cylinder is used, the method developed in Naval Ordnance Test Station TM-998 overestimates the viscous body lift.

NACA RM L55E11c

LOADS ON THIN WINGS AT TRANSONIC SPEEDS. Don D. Davis, Jr., and Gerald Hieser. June 1955. 17p. diagrs. (NACA RM L55E11c)

Experimental loads data at transonic speeds are reviewed in an attempt to sort out the effects of several configuration variables on the overall wing loads, and to establish the relative importance of these variables.

NACA RM L55E25b

EFFECT OF AUTOMATIC STABILIZATION ON THE SIDESLIP AND ANGLE-OF-ATTACK DISTURBANCES IN ROLLING MANEUVERS. Ordway B. Gates, Jr., Joseph Weil, and C. H. Woodling. July 1955. 18p. diagrs. (NACA RM L55E25b)

Time histories are presented that illustrate the large motions which have been encountered in flight tests of some of the present-day fighter airplanes. Results of some analog studies are discussed which indicate that variations in certain of the airplane stability derivatives could have an appreciable effect on these undesirable motions.

NACA RM L55G05a

A FREE-FLIGHT INVESTIGATION OF THE DRAG COEFFICIENTS OF TWO SINGLE-ENGINE SUPERSONIC INTERCEPTOR CONFIGURATIONS FROM MACH NUMBER 0.8 TO 1.90 TO DETERMINE THE EFFECT OF INLET AND ENGINE LOCATION. APPENDIX: SEPARATION CHARACTERISTICS OF A MODEL FROM A LARGE UNDERSLUNG BOOSTER AT MACH NUMBER 1.95. Joseph H. Judd. September 1955. 49p. diagrs., photos., tabs. (NACA RM L55G05a)

Flight tests for a Mach number range from 0.8 to 1.95 and a Reynolds number range from 3.8×10^6 to 16×10^6 were made for two complete single-engine interceptor configurations and an idealized configuration, all with 52.5° sweptback wings, NACA 65A004 airfoil sections, taper ratios of 0.2, and aspect ratios of 3.0. One airplane configuration had a half-conical spike scoop inlet under the fuselage, with the design engine location in the aft portion of the fuselage; and the other airplane configuration had a full-conical spike inlet ahead of the engine pod, which was located under the fuselage. The supersonic drag coefficients of the two interceptor models were approximately 0.025 for Mach numbers from 1.3 to 1.9. Separation characteristics of a model from a large underslung booster at a Mach number of 1.95 are presented in an appendix. Loads measured on an idealized configuration during separation from the booster reached maximum normal-force coefficients of ±0.137.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L55G08

TRANSONIC WIND-TUNNEL INVESTIGATION OF EFFECTS OF WINDSHIELD SHAPE AND CANOPY LOCATION ON THE AERODYNAMIC CHARACTERISTICS OF CANOPY-BODY COMBINATIONS. Elden S. Cornette and Harold L. Robinson. September 1955. 55p. diagrs. (NACA RM L55G08)

Force and moment test results are presented for a fuselage forebody and for canopy-body configurations consisting of four different canopies mounted on a fuselage forebody. Two of the canopies had the same shape and size rearward of the windshield but one had a "flat" and the other a "vee" windshield. The remaining two canopies were located at different body stations and were geometrically similar. The tests covered a Mach number range from 0.80 to 1.13, an angle-of-attack range from 0° to 10°, and an angle-of-sideslip range from -8° to 8°.

NACA RM L55G14

FREE-FLIGHT INVESTIGATION TO OBTAIN DRAG-AT-LIFT AND STABILITY DATA FOR A 60° DELTA-WING–BODY CONFIGURATION OVER A MACH NUMBER RANGE OF 1.3 TO 1.6. Clement J. Welsh. October 1955. 23p. diagrs., photo., tab. (NACA RM L55G14)

A 60° delta-wing–body configuration has been flight tested over a Mach number range of 1.3 to 1.6; the wing had an NACA 0003-63 airfoil section. Zero-lift drag, drag at lift, and stability data have been presented for the configuration. Also included are results of a simplified method to calculate aeroelasticity effects on the configuration, associated with the loss in lift and static longitudinal stability, relative to rigid-wing conditions.

NACA RM L55G19

AN EXPERIMENTAL STUDY OF A METHOD FOR DESIGNING FUSELAGE SIDE AIR INLETS FOR HIGH PERFORMANCE AT TRANSONIC AND LOW SUPERSONIC SPEEDS. Robert R. Howell and Charles D. Trescot, Jr. January 1956. 24p. diagrs., photos., tabs. (NACA RM L55G19)

A brief experimental investigation has been made of a method for designing fuselage side air inlets with high internal total-pressure recovery and zero spillage drag at a specified Mach number and inlet mass-flow ratio. Experimental evidence is also presented which indicates that a scoop-type air inlet designed according to this concept had near-zero spillage drag at the design inlet mass-flow ratio of 0.8 and internal total-pressure recovery up to 0.96 at a Mach number of 1.4 and an angle of attack of zero.

NACA RM L56C15

SOME NOTES ON THE VIOLENT LATERAL-LONGITUDINAL COUPLING MOTIONS OF THE DOUGLAS X-3 AIRPLANE IN AILERON ROLLS. Ralph W. Stone, Jr. May 1956. 35p. diagrs., tab. (NACA RM L56C15)

This paper presents the results of a study of the violent lateral-longitudinal coupling motions of the Douglas X-3 airplane in aileron rolls. Calculations using five degrees of freedom are included. The results, in addition to showing the importance of principal-axis inclination, pitching moment due to sideslip, and out-of-trim moments on the magnitude of the motions attained, indicate the present need for at least five-degrees-of-freedom calculations to evaluate a given design in rapid rolls. Calculations were also made to determine the effects of yawing moment due to sideslip and roll direction.

NACA RM L56G09

FREE-FLIGHT INVESTIGATION OVER A MACH NUMBER RANGE FROM 0.74 TO 1.43 AT LIFT COEFFICIENTS FROM -0.15 TO 0.75 OF AN AIRPLANE-CONFIGURATION MODEL HAVING A 52.5° DELTA WING AND A LOW SWEPT HORIZONTAL TAIL. Alan B. Kehlet. September 1956. 41p. diagrs., photos. (NACA RM L56G09)

A free-flight investigation was conducted on an airplane-configuration model having a 52.5° delta wing with NACA 65A003 airfoil sections in the streamwise direction. The configuration had a swept empennage with a horizontal tail of 45° quarter-chord-line sweep mounted in a low position. Characteristics of trim, drag, longitudinal static stability, and side force are presented. Comparisons of lift, drag, and longitudinal static stability from the same and from similar configurations are presented. Theoretical studies of lift, drag, longitudinal static stability, trim, and side-force derivative are included for comparison.

NACA RM L56G20

EXPERIMENTAL HINGE MOMENTS ON FREELY OSCILLATING FLAP-TYPE CONTROL SURFACES. C. William Martz. October 1956. 29p. diagrs., photos., tab. (NACA RM L56G20)

Oscillatory hinge-moment characteristics have been obtained from free-flight tests of two rocket-powered models each equipped with a 60° sweptback clipped delta wing featuring an unbalanced, constant-chord, full-span, trailing-edge control. One control had a sharp trailing edge, and the other had a trailing-edge thickness equal to 1/2 the thickness at the hinge line. Data were obtained at zero angle of attack and variable deflection amplitudes from $\pm 1^{\circ}$ to $\pm 14^{\circ}$. Control reduced frequencies ranged from 0.09 to 0.035. The Mach number range of the investigation was from 0.4 to 1.9.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM L56G31

WIND-TUNNEL MEASUREMENTS OF WING BUFFETING ON 1/16-SCALE MODEL OF DOUGLAS D-558-II RESEARCH AIRPLANE. William B. Kemp, Jr., and Thomas J. King, Jr. September 1956. 34p. diagrs.; photos., tabs. (NACA RM L56G31)

Exploratory measurements have been made of the fluctuations of wing bending moment during normal performance and stability wind-tunnel tests of a model of the Douglas D-558-II research airplane at Mach numbers from 0.60 to 0.96. The effects of leading-edge chord-extensions and several pylon-mounted underwing external stores were investigated. The standard deviation of the wing bending moment was found to be a qualitative indication of buffeting intensity.

This is authority for those possessing copies of the following research report to declassify it from Secret. Effective date of declassification June 24, 1958.

NACA RM E52C11

DISTRIBUTION OF FISSIONABLE MATERIAL IN THERMAL REACTORS OF SPHERICAL GEOMETRY FOR UNIFORM POWER GENERATION. Robert R. McCready, Robert B. Spooner, and Michael F. Valerino. June 1952. 36p. diagrs., tab. (NACA RM E52C11)

The two-group equations for reflected thermal reactors of spherical geometry are solved for constant power generation over the reactor-core volume. Illustrative calculations are made for specified core and reflector compositions and a range of reflector thicknesses to obtain the distributions of fissionable material over the reactor volume required to give uniform power generation. The calculations show that for reactors with moderate or thick reflectors substantial increase in reactor power output can be achieved.

Research Abstracts and Reclassification Notice

NO. 130 **SEPTEMBER 30, 1958**

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1322

METHOD FOR CALCULATING THE AERODYNAMIC LOADING ON AN OSCILLATING FINITE WING IN SUBSONIC AND SONIC FLOW. Harry L. Runyan and Donald S. Woolston. 1957. ii, 30p. diagrs., tabs. (NACA Rept. 1322. Supersedes TN 3694)

A method is presented for calculating the loading on a finite wing oscillating in subsonic or sonic flow. The method is applicable to any plan form and may be used for determining the loading on deformed wings. The procedure is approximate and requires a numerical integration over the wing surface.

NACA Rept. 1331

INFLUENCE OF ALLOYING UPON GRAIN-BOUNDARY CREEP. F. N. Rhines, W. E. Bond, and M. A. Kissel, Carnegie Institute of Technology. 1957. ii, 6p. diagrs., tab. (NACA Rept. 1331. Supersedes TN 3678)

Grain-boundary displacement, occurring in bicrystals during creep at elevated temperature (350° C), was measured as a function of the copper content (0.1 to 3 percent) in a series of aluminum-rich aluminum-copper solid-solution alloys. Because alloying effects alone were to be investigated, the conditions of observation were limited to a single temperature and range of stress.

NACA Rept. 1337

DETERMINATION OF LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS FROM FREE-FLIGHT MODEL TESTS WITH RESULTS AT TRANSONIC SPEEDS FOR THREE AIRPLANE CONFIGURATIONS. Clarence L. Gillis and Jesse L. Mitchell. 1957. ii, 28p. diagrs., photos., tabs. (NACA Rept. 1337)

Techniques have been developed for determining aerodynamic performance and the longitudinal stability and control parameters from an analysis of transient oscillations obtained in free-flight tests of rocket-propelled models. Details of the techniques have been indicated and the feasibility of the methods for determining both linear and nonlinear aerodynamic characteristics has been demonstrated by data measured in the transonic speed range on several airplane configurations.

NACA Rept. 1340

INVESTIGATION OF DOWNWASH, SIDEWASH, AND MACH NUMBER DISTRIBUTION BEHIND A RECTANGULAR WING AT A MACH NUMBER OF 2.41. David Adamson and William B. Boatright. 1957. ii, 57p. diagrs., photos., tab. (NACA Rept. 1340. Supersedes RM L50G12)

An investigation of the nature of the flow field behind a rectangular circular-arc wing at a Mach number of 2.41 has been made. Pitot- and static-pressure measurements in the flow field behind the wing and detailed pitot surveys throughout the viscous wake were made. The flow direction was measured by means of a weathercocking vane. Theoretical calculations of both sidewash and downwash using Lagerstrom's superposition method have been made and are compared with experiment. Modifications, where they are necessary to bring about better agreement between theory and experiment, are shown and discussed. These include the effect of the finite thickness of the wing and the displacement of the vortex sheet.

NACA Rept. 1343

A PHENOMENOLOGICAL RELATION BETWEEN STRESS, STRAIN RATE, AND TEMPERATURE FOR METALS AT ELEVATED TEMPERATURES. Elbridge Z. Stowell. 1958. ii, 6p. diagrs., tab. (NACA Rept. 1343. Supersedes TN 4000)

A phenomenological relation between stress, strain rate, and temperature is suggested to account for the behavior of polycrystalline metals above the equicohesive temperature. The properties of the metal included in the relation are elasticity, linear thermal expansion, and viscosity. The relation may be integrated under various conditions to provide information on creep rates, creep rupture, stress-strain curves, and rapid-heating curves. It is shown that for one material - 7075-T6 aluminum-alloy sheet - the information yielded by the relation for these four applications agrees reasonably well with test data.

NACA Rept. 1344

A SIMPLIFIED METHOD FOR APPROXIMATING THE TRANSIENT MOTION IN ANGLES OF ATTACK AND SIDESLIP DURING A CONSTANT ROLLING MANEUVER. Leonard Sternfield. 1958. ii, 11p. diagrs., tabs. (NACA Rept. 1344. Supersedes RM L56F04)

The pertinent modes of motion as well as the modal coefficient corresponding to each mode can be determined from the derived expressions for the transient motion in angles of attack and sideslip. Calculations

CURRENT NACA RESEARCH REPORTS

made with and without the derivatives C_{Y_β} (side force due to sideslip) and C_{L_α} (lift-curve slope) indicate that although these derivatives increase the total damping of the system, they do not markedly affect the transient motion.

NACA Rept. 1347

DITCHING INVESTIGATIONS OF DYNAMIC MODELS AND EFFECTS OF DESIGN PARAMETERS ON DITCHING CHARACTERISTICS. Lloyd J. Fisher and Edward L. Hoffman. 1958. ii, 28p. diagrs., tabs. (NACA Rept. 1347. Supersedes TN 3946)

Data from ditching investigations conducted at the Langley Aeronautical Laboratory with dynamic scale models of various airplanes are presented in the form of tables. The effects of design parameters on the ditching characteristics of airplanes, based on scale-model investigations and on reports of full-scale ditchings, are discussed. Various ditching aids are also discussed as a means of improving ditching behavior.

NACA RM A58C21

THE STATIC LONGITUDINAL CHARACTERISTICS OF A TWISTED AND CAMBERED 45° SWEPTBACK WING AT MACH NUMBERS UP TO 0.96. Robert I. Sammonds and Robert M. Reynolds. August 1958. 26p. diagrs., tab. (NACA RM A58C21)

The wing-body combination tested had a wing of aspect ratio 3 incorporating twist and a distributed type of camber. The wing thickness distribution perpendicular to the quarter-chord line was the NACA 64A006 with increased leading-edge radii. The camber of the central portion of the wing was an $a = 0.8$ (modified) mean line ($c_l = 0.2$) and the root and tip were an NACA 230 mean line ($c_l = 0.1$). Comparison of these data with similar data for a conically cambered wing having identical plan form and thickness ratio showed very little effect on the maximum lift-drag ratios due to the differences in camber.

NACA RM A58E02

WIND-TUNNEL INVESTIGATION AT MACH NUMBERS FROM 0.6 TO 1.4 OF SEVERAL EJECTED PILOT-SEAT MODELS. James L. Summers. September 1958. 47p. diagrs., photo., tabs. (NACA RM A58E02)

An experimental investigation was conducted to determine the static longitudinal and lateral directional aerodynamic characteristics of basic and modified versions of a conventional upward ejected pilot-seat combination, a sled-type upward ejected pilot-seat combination, and a downward ejected pilot-seat combination. Modifications to the basic models incorporated flow deflectors for pilot protection and drag reduction and various stabilizing devices. Test Mach numbers varied from 0.6 to 1.4, angles of attack from -28° to +40°, and angles of sideslip from -16° to +12°. Reynolds numbers ranged from 0.9 million to 1.8 million based on the projected frontal height of the models.

NACA RM L58C28a

LANDING AND TAXIING TESTS OVER VARIOUS TYPES OF RUNWAY LIGHTS. Robert C. Dreher and Sidney A. Batterson. August 1958. 39p. diagrs., photos., tabs. (NACA RM L58C28a)

An investigation was made at the Langley landing-loads track to obtain data on the landing-gear loads developed during landing and taxiing tests over various types of runway lights. The tests were made at forward speeds of 112 to 167 feet per second with a fighter nose landing gear and of 13.8 to 143 feet per second with a larger main landing gear. The results show the increase in loads caused by striking the lights.

NACA RM L58E09

WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC AND STRUCTURAL DEFLECTION CHARACTERISTICS OF THE GOODYEAR INFLATOPLANE. Bennie W. Cocke, Jr. September 1958. 56p. diagrs., photos. (NACA RM L58E09)

Tests of the Goodyear Inflatoplane were made in the Langley full-scale tunnel for a range of speeds from minimum stall speed up to speeds giving load factors for wing buckling. Static aerodynamic and control data with wing-deflection photographs and wing-guy-cable loads are presented.

NACA TM 1410

THEORY AND EXPERIMENTS ON SUPERSONIC AIR-TO-AIR EJECTORS. (Theorie et expérimentation des éjecteurs supersoniques air-air.) J. Fabri and J. Paulon. September 1958. 30p. diagrs. (NACA TM 1410. Translation of Office National d'Études et de Recherches Aéronautiques. Note Technique no. 36, 1956)

A comparison of experiment with theory is made for air ejectors having cylindrical mixing sections and operating under conditions of supersonic primary flow and either mixed or supersonic regimes of mixing. The effect on ejector performance of such parameters as mixer length and cross section, terminating diffuser, primary Mach number, and primary nozzle position is presented in terms of mass flow and pressure ratio.

CURRENT NACA RESEARCH REPORTS

NACA TM 1437

ON POSSIBLE SIMILARITY SOLUTIONS FOR THREE-DIMENSIONAL INCOMPRESSIBLE LAMINAR BOUNDARY-LAYER FLOW OVER DEVELOPABLE SURFACES AND WITH PROPORTIONAL MAINSTREAM VELOCITY COMPONENTS. Arthur G. Hansen, Case Institute of Technology. September 1958. (ii), 79p. diagrs. (NACA TM 1437)

Requirements for the existence of similarity solutions are obtained for boundary-layer equations expressed in orthogonal coordinates. Permissible forms of mainstream velocity components, the square of differential of arc length on the surface, and the similarity parameter are found. A basic class of surfaces is found from which all other permissible surfaces may be obtained. Necessary and sufficient conditions are found for expressing the ordinary differential equations resulting from the similarity transformation in uncoupled form. Uncoupling is possible only when the surface is developable and a surface coordinate system characterized by $(ds)^2 = (dx_1)^2 + (dx_2)^2$ is employed.

NACA TM 1438

ON THE FLUTTER OF CYLINDRICAL SHELLS AND PANELS MOVING IN A FLOW OF GAS. (O Flattere Tsilindricheskikh Obolochek i Panelei Dvizhushchikhsia V Potoke Gaza.) R. D. Stepanov. September 1958. 25p. diagrs., tabs. (NACA TM 1438. Translation from Prikladnaia Matematika i Mekhanika, v. 21, no. 5, 1957, p. 644-657)

The flutter of infinitely long closed cylinders, infinitely long cylindrical panels, and closed cylinders of finite length is investigated on the basis of Vlasov's shallow shell theory (also known as Donnell's theory) and a simpler approximate theory valid for shells of medium length. The air forces are given by piston theory. Values of a critical velocity above which finite steel cylinders with either simply supported or clamped ends may possibly flutter in sea-level air are tabulated for various ratios of thickness to radius and radius to length.

NACA TN 3883

PROPELLANT VAPORIZATION AS A CRITERION FOR ROCKET-ENGINE DESIGN; CALCULATIONS OF CHAMBER LENGTH TO VAPORIZE VARIOUS PROPELLANTS. Richard J. Priem. September 1958. 36p. diagrs., tab. (NACA TN 3883)

Vaporization rates of propellant sprays in a rocket combustor chamber were computed for n-heptane, ammonia, hydrazine, oxygen, and fluorine. Calculations were made for each propellant with various spray conditions, and various engine-design and operating parameters. The results are correlated with an effective length for ease in using them for design purposes. The calculations show that the effective chamber length required to vaporize a given high percentage of propellants is the shortest with oxygen and increases for fluorine, heptane, ammonia, and hydrazine in that order.

NACA TN 4005

AN EXPERIMENTAL INVESTIGATION OF THE EFFECT OF VARIOUS PARAMETERS INCLUDING TIP MACH NUMBER ON THE FLUTTER OF SOME MODEL HELICOPTER ROTOR BLADES. George W. Brooks and John E. Baker. September 1958. 68p. diagrs., photo., tabs. (NACA TN 4005. Supersedes RM L53D24)

Experimental studies have been made to evaluate the effects of parameters such as Mach number, blade angle, and structural damping on the flutter of model helicopter rotor blades in the hovering condition. The model blades had NACA 23012 and 23018 airfoil sections and each was tested at chordwise center-of-gravity locations of approximately 27.5 and 37 percent chord. Data were obtained at test-medium densities ranging from 0.0012 to 0.0030 slug per cubic foot and at various pitch angles up into the stall. Mixtures of air and Freon-12 were used for the test medium in order to extend the tip Mach number range of the tests to slightly above unity.

NACA TN 4016

SOME FACTORS AFFECTING THE VARIATION OF PITCHING MOMENT WITH SIDESLIP OF AIRCRAFT CONFIGURATIONS. Edward C. Polhamus. August 1958. 35p. diagrs., photo. (NACA TN 4016. Supersedes RM L55E20b)

A brief study of available wind-tunnel data with regard to the variation of pitching-moment coefficient with sideslip angle is presented. The effects of such factors as wing plan form, wing-body interference, and tail location are illustrated and discussed, and regions where additional data are needed are indicated.

NACA TN 4225

INTERNAL-FRICTION STUDY OF ALUMINUM ALLOY CONTAINING 4 WEIGHT PERCENT COPPER. B. S. Berry and A. S. Nowick, Yale University. August 1958. 88p. diagrs., tabs. (NACA TN 4225)

A study has been made, by means of low-frequency internal-friction measurements in both torsional and flexural vibration, of aluminum alloy containing 4-weight percent of copper during aging. Both polycrystalline and single-crystal specimens exhibit an initial internal-friction peak at 173° C (for a frequency of 1 cps) after solution treatment and quenching. This peak shows all the characteristics of a Zener relaxation, including strong anisotropy. The precipitation of the phase θ' is marked by the appearance of a second peak at 135° C (for a frequency of 1 cps) and by a rise in the high-temperature background internal friction. Possible causes of the second peak and the background changes are discussed.

NACA TN 4281

SECOND-ORDER SLENDER-BODY THEORY - AXISYMMETRIC FLOW. Milton D. Van Dyke. September 1958. (i), 46p. (NACA TN 4281)

Slender-body theory for subsonic and supersonic flow past bodies of revolution is extended to a second approximation. Methods are developed for handling the difficulties that arise at round ends. Comparison is made with experiment and with other theories for several simple shapes.

NACA TN 4285

TRANSGRANULAR AND INTERGRANULAR FRACTURE OF INGOT IRON DURING CREEP. L. A. Shepard and W. H. Giedt, University of California, Berkeley. August 1958. 26p. diagrs., photos., tabs. (NACA TN 4285)

Creep tests were performed on ingot iron at temperatures from 700° to 1,350° F to find whether the amount of grain-boundary sliding determined the fracture mode (transgranular or intergranular). If the mode were thus determined, a critical stress rather than a critical temperature would be the criterion for intergranular fracturing. Transgranular fractures were obtained below 800° F and above 20,000 psi. At higher temperatures, all fractures were intergranular. Tests indicated that intergranular fracturing may occur without grain-boundary shearing in the lower temperature range. It was concluded that a vacancy-condensation mechanism is most probably responsible for high-temperature intergranular fracturing in ingot iron.

NACA TN 4286

MECHANISM OF BENEFICIAL EFFECTS OF BORON AND ZIRCONIUM ON CREEP-RUPTURE PROPERTIES OF A COMPLEX HEAT-RESISTANT ALLOY. R. F. Decker and J. W. Freeman, University of Michigan. August 1958. 54p. diagrs., photos., tabs. (NACA TN 4286)

The effects of the addition of small amounts of boron and zirconium on creep properties of an alloy containing 55 percent nickel, 20 percent chromium, and 15 percent cobalt, with molybdenum, titanium, and aluminum were studied. These additions improved the creep-rupture properties at 1,600° F because of a stabilizing effect on the grain boundaries. These additions prolonged the life to fracture and allowed higher deformations before fracture. A number of optical and electron photomicrographs trace the development of microcracks and matrix changes through the creep process.

NACA TN 4287

RELATIONSHIP OF METAL SURFACES TO HEAT-AGING PROPERTIES OF ADHESIVE BONDS. J. M. Black and R. F. Blomquist, Forest Products Laboratory. September 1958. 30p. diagrs., tabs. (NACA TN 4287)

A study has been made to determine the probable causes of deterioration of each of several adhesives in bonds to stainless steel at temperatures from 400° to 550° F. Preliminary studies of aluminum surfaces on which ions of metals used in stainless steel were introduced showed that iron was probably catalyzing a thermal deterioration of the adhesive. The addition of zinc naphthenate, cerium naphthenate, or manganese dioxide increased the adhesive resistance to thermal deterioration. Other observations indicated probable specific relationships among the chemical structure of the adhesive, the metal adherent, and the resultant thermal stability of bonds after aging at high temperatures.

NACA TN 4288

TURBULENCE AND TEMPERATURE FLUCTUATIONS BEHIND A HEATED GRID. R. R. Mills, Jr., A. L. Kistler, V. O'Brien, and S. Corrsin, Johns Hopkins University. August 1958. 67p. diagrs. (NACA TN 4288)

In the approximately isotropic velocity and temperature fluctuation fields behind a hot grid, measurements were made of fluctuation levels and of various double and triple correlation functions. The double and triple correlation coefficient functions are of roughly the same spatial extent for the vector and scalar fields. As anticipated from theoretical considerations, the temperature fluctuations die out more slowly than does the turbulence.

NACA TN 4302

ANALYTICAL AND EXPERIMENTAL INVESTIGATION OF AERODYNAMIC FORCES AND MOMENTS ON LOW-ASPECT-RATIO WINGS UNDERGOING FLAPPING OSCILLATIONS. Donald S. Woolston, Sherman A. Clevenson, and Sumner A. Leadbetter. August 1958. 25p. diagrs., tab. (NACA TN 4302)

Forces and moments associated with flapping oscillations of finite wings at low speeds are considered. A comparison of theoretical results, based on lifting-surface theory, and experimental results is made for a rectangular wing of aspect ratio 2. Calculated results are also given for three tapered wings of aspect ratio 3 with varying amounts of sweepback.

CURRENT NACA RESEARCH REPORTS

NACA TN 4304

MATRIX METHOD FOR OBTAINING SPANWISE MOMENTS AND DEFLECTIONS OF TORSIONALLY RIGID ROTOR BLADES WITH ARBITRARY LOADINGS. Alton P. Mayo. August 1958. 51p. diagrs., tabs. (NACA TN 4304)

The method includes the cantilever, teetering, and hinged blades in hovering and in steady forward flight. The method is comparatively short, involves only standard matrix procedures, and does not require that the mode shapes or natural frequencies be known.

NACA TN 4306

TEMPERATURE AND THERMAL-STRESS DISTRIBUTIONS IN SOME STRUCTURAL ELEMENTS HEATED AT A CONSTANT RATE. William A. Brooks, Jr. August 1958. 77p. diagrs., tab. (NACA TN 4306)

Analytical solutions are given for the temperature and thermal-stress distributions in thick skins and structural elements such as angle, channel, T-, and H-sections when heated at a constant rate. Certain of the analytical solutions are evaluated for selected cross-sectional proportions. The results are presented in the form of charts involving dimensionless temperature, stress, and time parameters and therefore are applicable for different materials and heating rates and absolute size of the section. The results have been found useful for analyzing and correlating experimental data.

NACA TN 4307

EXPERIMENTAL MEASUREMENTS OF THE EFFECTS OF AIRPLANE MOTIONS ON WING AND TAIL ANGLES OF ATTACK OF A SWEPT-WING BOMBER IN ROUGH AIR. Jerome N. Engel. August 1958. 25p. diagrs., photo., tabs. (NACA TN 4307)

Flight-test data obtained from an airplane at an altitude of 5,000 feet are analyzed to determine the effects of airplane vertical translation and pitching motions. Power-spectral techniques are used in order to determine the contributions of these motions to the angles of attack of the wing and tail at various frequencies, and these results are compared with the direct gust-induced angle of attack.

NACA TN 4316

FRICTION AND WEAR WITH REACTIVE GASES AT TEMPERATURES UP TO 1200° F. Gordon P. Allen, Donald H. Buckley, and Robert L. Johnson. September 1958. 26p. diagrs., photos. (NACA TN 4316)

CF_2C1_2, CF_3C1, and SF_6 gases were used to lubricate hardened M-1 tool steel and other materials. A hemisphere rider (3/16-in. rad.) under a 1200-g load slid on a rotating disk at 120 ft/min. CF_2C1_2 was effective up to 1200° F and CF_3C1, while not as good a lubricant, gave less corrosion. Small amounts of SF_6 added to CF_2C1_2 improved lubrication. SF_6 alone reduced wear but not friction of tool steel sliding against tool steel. Of the iron, copper, and nickel alloys studied, silicon-nickel alloys gave the best results. With silicon nickel, SF_6 gave both low wear and low friction at 600° F. For steel, corrosion was important with all gases.

NACA TN 4317

TURBOJET ENGINE NOISE REDUCTION WITH MIXING NOZZLE-EJECTOR COMBINATIONS. Willard D. Coles, John A. Mihaloew, and Edmund E. Callaghan. August 1958. 33p. diagrs., photos., tab. (NACA TN 4317)

Maximum sound pressure level reductions of 12 decibels and sound power level reductions of 8 decibels were obtained with lobe nozzle and ejector combinations on two full-scale engines. The ejectors provided 3 to 5 decibels of the sound power level reduction. Several combinations of ejectors and nozzles were used and acoustic and engine performance data are presented. A study of jet profiles and boundaries at the ejector exit shows the effectiveness of the lobe nozzle and ejector combinations in diffusing the jet to a larger, lower velocity stream. Calculated noise reductions based on ejector exit flow conditions are not realized experimentally, probably because the noise generated inside the ejector is appreciable.

NACA TN 4320

COMPRESSIBLE LAMINAR FLOW AND HEAT TRANSFER ABOUT A ROTATING ISOTHERMAL DISK. Simon Ostrach and Philip R. Thornton. August 1958. 18p. diagrs., tab. (NACA TN 4320)

The flow and heat transfer about a rotating isothermal disk are reexamined to include the effects of compressibility and property variations. If viscous dissipation is neglected, the compressible problem is correlated to the incompressible problem by assuming linear variations of viscosity and thermal conductivity with temperature. Certain inaccuracies in several previous incompressible solutions are noted and corrected. The effect of compressibility appears as a distortion of the normal coordinate and normal velocity component and as a multiplicative factor in the heat-transfer coefficient, the Nusselt number, and in the expressions for the skin-friction components and torque required to rotate the disk.

NACA TN 4321

AN ANALYTICAL STUDY OF TURBULENT AND MOLECULAR MIXING IN ROCKET COMBUSTION. David A. Bittker. September 1958. 22p. diagrs. (NACA TN 4321)

Approximate calculations for the diffusion of gases have been performed to obtain an idea of the importance of gaseous mixing in rocket combustion. Mixing lengths for two simplified diffusion models are

CURRENT NACA RESEARCH REPORTS

calculated for various turbulence conditions. Results are independent of any particular propellant combination. With sources in a single injection plane, mixing occurs in less length than is needed for evaporation of typical engine sprays. When downstream sources are used to simulate vaporization within the chamber, mixing is more significant. Calculations only indicate the magnitude of the effect since the models used are greatly simplified.

NACA TN 4323

NATURAL CONVECTION INSIDE A FLAT ROTATING CONTAINER. Simon Ostrach and Willis H. Braun. September 1958. 27p. diagrs. (NACA TN 4323)

Froude number is found to be the parameter that determines the effect of body rotations on internal natural convection flows. Explicit forms of Froude number are determined for the cases of predominant rotation and predominant axial force. In a heated flat cylindrical container no significant convective effects are generated by rotations alone. Moreover, rotation tends to inhibit the flow and heat transfer generated by an axial body force in such a configuration. Insertion of radial vanes in the container eliminates the detrimental effects of rotation and improves the heat transfer.

NACA TN 4324

METHOD FOR DETERMINING THE NEED TO REWORK OR REPLACE COMPRESSOR ROTOR BLADES DAMAGED BY FOREIGN OBJECTS. Albert Kaufman. September 1958. 25p. diagrs., photo. (NACA TN 4324)

This method includes the effects of the location and depth of damage, the material fatigue strength and notch sensitivity, and the maximum-vibratory-stress level of the blade in engine operation. The method was compared with experimental results from fatigue tests of blades edge-nicked in the laboratory and was found to be an acceptable basis for blade inspection. The amount of strength restored by reworking the damaged area was also investigated.

NACA TN 4325

A MACH 4 ROCKET-POWERED SUPERSONIC TUNNEL USING AMMONIA-OXYGEN AS WORKING FLUID. Robert W. Graham, Eleanor Costilow Guentert, and Vearl N. Huff. September 1958. 53p. diagrs., photos. (NACA TN 4325)

To simulate the high heating rates encountered in hypersonic flow, the exhaust gases from an ammonia-oxygen rocket have been used to power a supersonic tunnel. A gas temperature of 4500° R at Mach 4 was produced in the 15-inch test section of the tunnel. The calibration pressure data indicate reproducibility of test conditions in this facility. Physical, transport, and one-dimensional aerodynamic data for combustion products of ammonia and oxygen are included.

NACA TN 4328

STUDY OF HYDROGEN EMBRITTLEMENT OF IRON BY INTERNAL-FRICTION METHODS. R. E. Maringer, E. B. Swetnam, L. L. Marsh, and G. K. Manning, Battelle Memorial Institute. September 1958. 62p. diagrs., photos., tab. (NACA TN 4328)

The effects of electrolytic charging on the properties of relatively pure iron and tempered 4340 steel were investigated metallographically and by observing internal-friction behavior from -196° to 430° C. Severe structural damage, consisting of blisters and internal cracks, resulted even after comparatively short charging times. The internal friction of recrystallized iron was particularly sensitive to hydrogen charging. Internal friction of iron and steel below room temperature exhibits phenomena resulting from the interaction of hydrogen atoms and moving dislocations.

NACA TN 4339

HYDRODYNAMIC IMPACT LOADS OF A -20° DEAD-RISE INVERTED-V MODEL AND COMPARISONS WITH LOADS OF A FLAT-BOTTOM MODEL. Philip M. Edge, Jr. August 1958. 36p. diagrs., photo., tabs. (NACA TN 4339)

Hydrodynamic-impact-loads data were obtained at the Langley impact basin from tests of a narrow-beam model. Fixed-trim impacts were made in smooth water over a range of landing conditions at a beam-loading coefficient of 19.15, with a few impacts at beam-loading coefficients of 27.90 and 36.07. Loads, moments, motions, and bottom pressures were measured throughout each of the impacts. The maximum impact loads for the inverted-V model are compared with loads obtained for a flat-bottom model.

NACA TN 4343

A COMPARISON OF TWO METHODS FOR CALCULATING TRANSIENT TEMPERATURES FOR THICK WALLS. James J. Buglia and Helen Brinkworth. August 1958. 19p. diagrs., tab. (NACA TN 4343)

A comparison is made of two different methods of calculating transient temperatures for thick walls with arbitrary variation of heat-transfer coefficient and adiabatic-wall temperature. Numerical calculations for special cases for which the exact solutions are available show that both methods give accurate results. Hill's method (NACA Technical Note 4105) is shown to be generally superior to Dusinberre's method (Trans. A.S.M.E., vol. 67, no. 8) in both speed and accuracy, if a table of memory coefficients is available.

CURRENT NACA RESEARCH REPORTS

NACA TN 4344

PERFORMANCE AT LOW SPEEDS OF COMPRESSOR ROTORS HAVING LOW-CAMBERED NACA 65-SERIES BLADES WITH HIGH INLET ANGLES AND LOW SOLIDITIES. James C. Emery and Paul W. Howard. August 1958. 28p. diagrs. (NACA TN 4344)

Tests were made on three blades at solidities of 0.5, 0.75, and 1.0, without guide vanes or stators, over ranges of blade-setting angles and quantity-flow rates. The performance measured in these tests is compared with performance estimated from two-dimensional cascade data for the purpose of extending the correlation of cascade and compressor-rotor data over a range of high-inlet-angle conditions.

NACA TN 4346

APPROXIMATE METHOD FOR CALCULATING MOTIONS IN ANGLES OF ATTACK AND SIDESLIP DUE TO STEP PITCHING- AND YAWING-MOMENT INPUTS DURING STEADY ROLL. Martin T. Moul and Teresa R. Brennan. September 1958. 42p. diagrs., tabs. (NACA TN 4346)

The method presented herein for calculating airplane response in a steady roll to pitching- and yawing-moment inputs approximates the complete four-degree-of-freedom steady-roll response by neglecting the high-frequency mode and simplifying the remaining modal coefficients. This technique was employed in NACA Report 1344 to approximate the airplane response due to angle of attack of the principal axis. Motions from the approximate method are compared with five-degree-of-freedom solutions, and a procedure for applying the method to design calculations is suggested.

NACA TN 4348

EFFECT OF TEMPERATURE ON DYNAMIC MODULUS OF ELASTICITY OF SOME STRUCTURAL ALLOYS. Louis F. Vosteen. August 1958. 19p. diagrs., tabs. (NACA TN 4348)

The effect of temperature on Young's modulus of elasticity was determined from flexural beam vibration tests for 2024-T3 and 7075-T6 aluminum alloys, AZ31A-0 magnesium alloy, RS-120 titanium alloy, and type 303 stainless steel at temperatures from room temperature to 900° F. The test frequencies were varied from 40 to 550 cycles per second. The results are compared with values of moduli obtained from conventional stress-strain tests. The data show that the dynamic modulus decreases with temperature but does not decrease as rapidly as the static modulus. It is shown that the difference between the static modulus and dynamic modulus is due to internal friction and cannot be attributed to creep.

NACA TN 4350

THEORETICAL DISTRIBUTION OF LAMINAR-BOUNDARY-LAYER THICKNESS, BOUNDARY-LAYER REYNOLDS NUMBER AND STABILITY LIMIT, AND ROUGHNESS REYNOLDS NUMBER FOR A SPHERE AND DISK IN INCOMPRESSIBLE FLOW. Neal Tetervin. September 1958. 36p. diagrs. (NACA TN 4350)

Calculations have been made by use of an approximate method for a sphere in the supercritical Reynolds number region. The same quantities have also been calculated for the front face of a much blunter body, namely, for a disk. For the disk the unusual result obtained was that the boundary-layer thickness decreased with an increase in distance from the stagnation point. Only at extremely large Reynolds numbers did the laminar boundary layer over a disk or over the forward portion of a sphere become unstable with respect to the Tollmien-Schlichting type of waves.

NACA TN 4353

EXPLORATORY WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC AND TRANSONIC SPEEDS OF JET FLAPS ON UNSWEPT RECTANGULAR WINGS. Vernard E. Lockwood and Raymond D. Vogler. August 1958. 37p. diagrs. (NACA TN 4353)

The investigation was conducted on an unswept rectangular NACA 65A006 wing with an aspect ratio of 3.33 and a much thicker wing of the same plan form which were modified at the trailing edges to provide several jet-flap configurations. Most of the data were obtained at an angle of attack of 0°. Lift, drag, and pitching-moment data are presented for a momentum-coefficient range varying from 0.30 at a Mach number of 0.40 to 0.03 at a Mach number of 1.10.

NACA TN 4354

MEASUREMENTS IN A SHOCK TUBE OF HEAT-TRANSFER RATES AT THE STAGNATION POINT OF A 1.0-INCH-DIAMETER SPHERE FOR REAL-GAS TEMPERATURES UP TO 7,900° R. Alexander P. Sabol. August 1958. 15p. diagrs., photos., tab. (NACA TN 4354)

The heat-transfer rates were determined at Mach numbers between 6.4 and 13.9 from measurements of the surface-temperature change with time of a thin-film-platinum resistance surface thermometer. The test results are presented and compared with the predictions of two theories, and the compatibility of these results with other experimental results obtained with both a thin-film surface thermometer and a calorimeter-type gage is pointed out. Data from tests in which a thin-film thermocouple was used are also included for comparison.

CURRENT NACA RESEARCH REPORTS

NACA TN 4356

EFFECTS OF COMPRESSIBILITY ON ROTOR HOVERING PERFORMANCE AND SYNTHESIZED BLADE-SECTION CHARACTERISTICS DERIVED FROM MEASURED ROTOR PERFORMANCE OF BLADES HAVING NACA 0015 AIRFOIL TIP SECTIONS. James P. Shivers and Paul J. Carpenter. September 1958. 28p. diagrs. (NACA TN 4356)

An investigation has been conducted at the Langley helicopter test tower to determine the low tip Mach number blade maximum mean lift coefficient and high tip Mach number compressibility effects. Data are presented for blade tip Mach numbers from 0.27 to 0.81 and corresponding Reynolds numbers from 1.64×10^6 to 4.78×10^6. Synthesized rotor-blade section-lift and profile-drag-coefficient data derived from experimental data are presented and compared with previously obtained two-dimensional data.

NACA TN 4357

LIFT AND PROFILE-DRAG CHARACTERISTICS OF AN NACA 0012 AIRFOIL SECTION AS DERIVED FROM MEASURED HELICOPTER-ROTOR HOVERING PERFORMANCE. Paul J. Carpenter. September 1958. 28p. diagrs., photo. (NACA TN 4357)

Rotor hovering performance from which the major portion of the synthesized data were derived is presented for tip Mach numbers from 0.28 to 0.70. The principal effect of increasing the blade-tip Mach number is a large increase in blade drag which occurs at a progressively lower blade mean lift coefficient as the tip Mach number is increased. These synthesized airfoil data should be useful in helicopter-rotor-performance calculations.

NACA TN 4358

SUPERSONIC WAVE INTERFERENCE AFFECTING STABILITY. Eugene S. Love. September 1958. 19p. diagrs., photos. (NACA TN 4358. Supersedes RM L55L14a)

Some of the significant interference fields that may affect stability of aircraft at supersonic speeds are briefly summarized. Illustrations and calculations are presented to indicate the importance of interference fields created by wings, bodies, wing-body combinations, jets, and nacelles.

NACA TN 4360

MEASUREMENTS OF THE EFFECTS OF WALL OUTFLOW AND POROSITY ON WAVE ATTENUATION IN A TRANSONIC WIND TUNNEL WITH PERFORATED WALLS. Joseph M. Spiegel, Phillips J. Tunnell, and Warren S. Wilson. August 1958. 27p. diagrs. (NACA TN 4360)

Various wind-tunnel perforated-wall configurations were tested in the transonic speed range to evaluate the effects of wall outflow and wall porosity on the wave reflection on various models in the test section. The maximum outflow was 9.5 percent of the total mass flow and the porosity was varied from 0.60 to 24.4 percent open.

NACA TN 4366

THE EFFECTS OF AN INVERSE-TAPER LEADING-EDGE FLAP ON THE AERODYNAMIC CHARACTERISTICS IN PITCH OF A WING-BODY COMBINATION HAVING AN ASPECT RATIO OF 3 AND 45° OF SWEEPBACK AT MACH NUMBERS TO 0.92. Fred A. Demele and K. Harmon Powell. August 1958. 57p. diagrs., photo., tabs. (NACA TN 4366)

An investigation has been conducted to determine the effectiveness of a leading-edge flap in improving primarily the drag characteristics of a swept-wing-body combination. With the flap deflected, the wing had a camber and twist distribution similar to that resulting from the incorporation of conical camber in the forward portion of a plane wing. Aerodynamic data were obtained for flap angles to 16° over a Mach number range of 0.25 to 0.92 at a Reynolds number of 3.2 million, and over a Reynolds number range of 3.2 to 15 million at a Mach number of 0.25. Lift-drag ratios are compared with those of a similar model incorporating conical camber.

NACA TN 4371

SOME OBSERVATIONS RELATING TO RECOVERY OF INTERNAL FRICTION DURING FATIGUE OF ALUMINUM. S. R. Valluri, California Institute of Technology. September 1958. 30p. diagrs., tab. (NACA TN 4371)

Recovery of internal friction during periods of rest in specimens subjected to fatigue stresses in torsion was studied experimentally with high-purity aluminum. The effective heat of activation for the process is found to be about 10,000 calories per gram molecule or less. The dislocations responsible for the recovery of internal friction may be the same as those responsible for fine slip which, according to one existing theory, is the mechanism responsible for fatigue failure. Experimental results indicate that obtaining a recovery factor independent of stressing history may possibly be associated with installing a cyclic process in which the subgrain structure is well established.

CURRENT NACA RESEARCH REPORTS

NACA TN 4374

RATE OF REACTION OF GASEOUS FLUORINE WITH WATER VAPOR AT 35° C. Vernon A. Slabey and Edward A. Fletcher. September 1958. 16p. diagrs., tabs. (NACA TN 4374)

Fluorine and water vapor react extremely slowly or not at all in the gas phase at 35° C at partial pressures of the reactants up to 40 mm of mercury. They react at surfaces; the kinetics are first order with respect to each of the reactants. At Kel-F wax-coated surfaces, the rate of disappearance of fluorine is expressed by $-\frac{dF_2}{dt} = 1.6 \times 10^{-4} A_w [F_2][H_2O]$, where $-\frac{dF_2}{dt}$ is the rate of disappearance of fluorine in moles per second, A_w is the surface area (sq cm) of the reaction vessel, and $[F_2]$ and $[H_2O]$ are the concentrations in moles per liter of the reactants. Neither ozone nor hydrogen peroxide is formed to a measurable extent in the reaction.

NACA TN 4375

APPROXIMATE SOLUTIONS OF A CLASS OF SIMILARITY EQUATIONS FOR THREE-DIMENSIONAL, LAMINAR, INCOMPRESSIBLE BOUNDARY-LAYER FLOWS. Arthur G. Hansen and Howard Z. Herzig. September 1958. 26p. diagrs. (NACA TN 4375)

An analysis is presented for obtaining approximate solutions of the similarity equations for three-dimensional laminar-boundary-layer flows over a flat surface under main-flow streamlines that are translates and representable as infinite series expansions. For the particular case of streamline shapes described by a power of the distance along the surface from the leading edge, relatively simple expressions are obtained for flow deflection at the bounding surface, limiting streamline shape, and shear stress at the surface.

NACA TN 4388

EFFECTS OF NOSE ANGLE AND MACH NUMBER ON TRANSITION ON CONES AT SUPERSONIC SPEEDS. K. R. Czarnecki and Mary W. Jackson. September 1958. 17p. diagrs., photo. (NACA TN 4388)

An investigation has been made to determine the transition characteristics of a group of smooth, sharp-nosed cones varying from 10° to 60° in included apex angle over a Mach number range from 1.61 to 2.20 and a range of Reynolds number per foot from about 1.5×10^6 to 8×10^6. Increasing the cone angle is shown to decrease slightly the transition Reynolds number, whereas the effects of changes of Mach number and unit Reynolds number are negligible. When transition occurred within 15 to 20 percent of the model length from the base there was a dropoff in transition Reynolds number.

NACA TN 4389

EFFECT OF ADVANCE RATIO ON FLIGHT PERFORMANCE OF A MODIFIED SUPERSONIC PROPELLER. Jerome B. Hammack and Thomas C. O'Bryan. September 1958. 20p. diagrs., photos. (NACA TN 4389)

Results of a flight investigation of a modified supersonic propeller at the design Mach number of 0.95 indicated a propeller efficiency of approximately 79 percent. The departure from optimum angle of advance has a small effect for the advance ratios investigated.

NACA TN 4390

EFFECTS OF FREQUENCY AND AMPLITUDE ON THE YAWING DERIVATIVES OF TRIANGULAR, SWEPT, AND UNSWEPT WINGS AND OF A TRIANGULAR-WING—FUSELAGE COMBINATION WITH AND WITHOUT A TRIANGULAR TAIL PERFORMING SINUSOIDAL YAWING OSCILLATIONS. William Letko and Herman S. Fletcher. September 1958. 52p. diagrs., photos., tabs. (NACA TN 4390)

Except for the complete wing-fuselage-tail configuration the results indicate that the damping in yaw and the rolling moment due to yawing increase with angle of attack, and at high angles of attack the oscillatory values are considerably greater than the steady-state values. The values of the oscillatory derivatives for the complete-model configuration are considerably greater than the steady-state values through the entire angle-of-attack range. In general, the greatest changes in yawing derivatives with amplitude and frequency occurred in the low range of amplitude and frequency.

NACA TN 4392

A THEORETICAL STUDY OF STAGNATION-POINT ABLATION. Leonard Roberts. September 1958. 29p. diagrs. (NACA TN 4392)

A simplified analysis is made of ablation cooling near the stagnation point of a two-dimensional or axisymmetric body which occurs as the body vaporizes directly from the solid state. The automatic shielding mechanism is discussed and the important thermal properties required by a good ablation material are given. The results of the analysis are given in terms of dimensionless parameters.

SUPERSONIC FLOW PAST QUASI-CYLINDRICAL BODIES OF ALMOST CIRCULAR CROSS-SECTION. D. G. Randall. 1958. 17p. diagrs., tabs. ARC R & M 3067; ARC 836. Supersedes RAE Tech.Note Aero 2404. (Ask for N-42171X*)

The supersonic flow over bodies for which surface boundary condition may be satisfied on a circular cylinder is considered. The method is based on the linearized small-perturbation theory of supersonic flow. The disturbance velocity potential is obtained as a Fourier series each term of which contains a certain basic function and the first 11 of these functions are evaluated. The pressure distribution and wave drag have been calculated for some bodies consisting of circular cylinders surmounted by canopies. An extension of the method to solve certain wing-body interference problems is also described.

Aeronautical Research Council (Gt. Brit.)
WIND-TUNNEL TESTS ON THE EFFECT OF BODY FREEDOMS ON THE FLUTTER OF A MODEL WING CARRYING A LOCALISED MASS. D. R. Gaukroger and E. W. Chapple. 1958. 33p. diagrs. ARC R & M 3081; ARC 18,725. Supersedes RAE Report Structures 204. (Ask for N-44963X*)

Wind-tunnel test results for the flutter of a sweptback wing carrying a localized mass, and having symmetric or antisymmetric freedoms of the root, are given. The tests were made on a model wing of 23° sweepback, the chordwise and spanwise positions of a localized mass being varied for two localized mass values. In most of the symmetric flutter tests the inertia conditions of the fuselage were constant and representative of full scale. For the antisymmetric tests, the fuselage rolling moment of inertia was varied. The test results indicate that, in general, the symmetric flutter case is more critical than the antisymmetric for masses at outboard positions on the wing, but for heavy inboard masses the antisymmetric case may be the more critical. The results are too complex for any detailed use in predicting the effects of mass loading on the flutter of particular aircraft.

SUPERSONIC WIND-TUNNEL FLUTTER TESTS OF TWO RECTANGULAR WINGS. P. R. Guyett. 1958. 15p. diagrs., photos., tabs. ARC R & M 3080; ARC 18,760. Supersedes RAE Report Structures 206. (Ask for N-46420X*)

Two rectangular wings were flutter tested in a supersonic wind tunnel using a technique in which a structural stiffness was varied to give flutter at the Mach number. Results are in reasonable agreement with calculations using theoretical three-dimensional derivatives and arbitrary wing modes, though the calculated critical stiffnesses are rather higher than the test values. It is shown theoretically that structural damping has an important effect upon stiffness required to avoid flutter, and may be destabilizing.

OPERATIONAL FORMULAE FOR RESPONSE CALCULATIONS. S. Neumark. 1958. 48p. diagrs., tabs. ARC R & M 3075; ARC 18,941. Supersedes RAE Report Aero 2570. (Ask for N-46784X*)

The paper presents systematic tables of formulas whose purpose is to facilitate the operational solution of response problems reducible to linear differential equations with constant coefficients and with simple forcing functions. The formulas enable the user to find operational equivalents of a wide class of simple functions and to find functional equivalents of a great number of operational expressions. The introductory text describes the method of deriving the formulas and explains how to use them in solving response problems. A number of examples are appended which show the advantages of the tables and give solutions of several typical problems.

SOME CONTRIBUTIONS TO JET-FLAP THEORY AND TO THE THEORY OF SOURCE-FLOW FROM AEROFOILS. L. C. Woods. 1958. 37p. diagrs. ARC CP 388. (Ask for N-50085X*)

This paper presents a theoretical study of the thrust, lift, and moment on an airfoil due to a two-dimensional jet of air ejected from the trailing edge at an angle τ to the main stream. It is rigorously proved that in subsonic compressible flow the ideal thrust of the jet (assumed not to mix with the main stream) is independent of the exit angle τ. The theory for the lift and moment is developed for incompressible flow only. It is not rigorous, being based on the assumption that jets of equal momentum and at equal values of τ have essentially the same influence on the main stream. The theory is in satisfactory agreement with the few experimental values available. Two appendixes have been added to the paper.

METHODS FOR DETERMINING THE WAVE DRAG OF NON-LIFTING WING-BODY COMBINATIONS. L. M. Sheppard. 1958. 28p. diagrs. ARC R & M 3077; ARC 19,320. Supersedes RAE Report Aero 2590. (Ask for N-50128X*)

The area rule, moment of area rule, and transfer rule methods for estimating the wave drag of wing-body combinations are discussed. It is pointed out that the moment of area rule and the transfer rule are different forms of the area rule, and that the transfer rule expresses the interference wave drag in a simple form. The existing methods of wave-drag estimation are restricted to combinations with bodies having continuous surface slope and here an extension to combinations with bodies having discontinuous surface slope is given. This paper is concerned with the theoretical methods and their associated numerical techniques and no numerical results or particular applications are presented.

AN INVESTIGATION OF THE NOISE PRODUCED BY A SUBSONIC AIR JET. J. H. Gerrard, University of Manchester. June 30, 1955. 34p. diagrs., tabs. ARC 17,724; FM 2270. (Ask for N-62511*)

To investigate the theoretical predictions of Lighthill on aerodynamic sound, measurements have been made of the sound field of a 1-inch air jet issuing from a long pipe. The measurements have been made over a wide frequency band (30 to 10,000 cycles/sec) and in 1/3 octave bands in this frequency range. The mean Mach number at the pipe orifice was varied from 0.3 to 1.0. The dependence of the apparent position of the noise sources on frequency and jet speed was investigated. The dependence of the noise intensity upon jet speed is examined in terms of the power law relation.

A THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE FLOW OVER A FAMILY OF RECTANGULAR WINGS OF BICONVEX SECTION AT $M = 1.42$. R. C. Lock. 1958. 43p. diagrs., photos. ARC R & M 3055; ARC 18,331. (Ask for N-62776*)

An account is given of experiments made at $M = 1.42$ using three rectangular half-wing models having biconvex sections with thickness ratios 0.04, 0.06, and 0.08, mounted on a reflection plate. Measurements

BRITISH REPORTS

were made of the pressure on the upper surface of the wing and of pressure and flow direction in the neighborhood of the wing tip. Direct shadow photography and observation of surface-oil patterns enabled various details of the flow to be visualized. The results are correlated with the linearized theory and with certain second-order modifications to this theory. It is found that in general the linearized theory provides a sufficient approximation to the detailed flow only for the thinnest wing at very small incidences. In most cases the suggested modifications effect a considerable improvement.

PRESSURE-PLOTTING MEASUREMENTS ON AN 8 PER CENT THICK AEROFOIL WITH TRAILING-EDGE FLAP BLOWING. J. Williams and A. J. Alexander, National Physical Laboratory. 1958. 34p. diagrs., photo., tab. ARC R & M 3087; ARC 18,487. (Ask for N-62777*)

Wind-tunnel experiments were carried out on an 8-percent-thick airfoil between end plates, with blowing from a slot in the knee of a 25-percent-chord trailing-edge flap, to improve the lifting efficiency of the flap. Both the blowing-slot width and position were varied. The sectional lift and pitching moment were derived by chordwise integration of the surface static pressures measured at the midspan station. Tuft observations as well as surface-pressure measurements were made to determine the extent of the turbulent separation region on the trailing-edge flap and of the laminar separation bubble on the airfoil nose.

THE INFLUENCE OF A MODEL ON PLENUM CHAMBER INDICATION OF MACH NUMBER IN A SLOTTED WALL WIND TUNNEL. L. C. Squire and A. Stanbrook. February 1958. 14p. diagrs. RAE Tech.Note Aero 2541. (Ask for N-63247*)

In many transonic tunnels the Mach number in the working section is determined from a pressure measured in the plenum chamber, on the assumption that this pressure is uniquely related to the free-stream static pressure. The effect of a number of different sting-mounted models on this relationship has been investigated in the 3-ft tunnel at RAE Bedford. The results show that the Mach number determined from the pressure in the plenum chamber is not affected by the presence of any of the models in the working section, provided that the pressure is not measured near the downstream end of the plenum chamber.

National Gas Turbine Establishment (Gt. Brit.)
A TURBINE NOZZLE CASCADE FOR COOLING STUDIES. PART II - COMPARISON BETWEEN MEASURED AND PREDICTED MEAN NUSSELT NUMBERS AT THE BLADE SURFACE. R. I. Hodge. May 1958. 39p. diagrs. NGTE Memo. M.309. (Ask for N-63426, pt.2*)

The condition of the boundary layer around a turbine nozzle blade profile in a two-dimensional cascade is described at various levels of gas flow Reynolds number and turbulence. Mainstream turbulence is shown to have a modifying influence on the accepted transition criteria. Surface distributions of heat-transfer coefficient are calculated for the near isothermal case, with laminar and turbulent boundary layers. Ad hoc experiments are reported which give the blade-surface heat-transfer coefficients when the boundary layer is separated over part of the convex side. The combined calculated and estimated values of the profile average heat-transfer rate, according to the estimated boundary-layer development pattern with flow Reynolds number, are in fair agreement with the measured values quoted in part I of the present pair of memorandums.

Directorate of Guided Weapons Research and Development (Gt. Brit.) SUPERSONIC JET DEFLECTION. PART VI. DEFLECTION BY A SLIDING BEVELLED SLEEVE OR UNGULUS. P. N. Rowe. October 1957. 7p. diagrs., photos., tab. D.G.G.W. Report/EMR/58/5. (Ask for N-64033*)

Describes experiments carried out with a nozzle surrounded by a cylindrical sleeve having a beveled exit plane slidably mounted on the nozzle so as to progressively expose an ungular surface to the jet. It is concluded that the deflection of a supersonic jet by using an ungular sleeve is an efficient method. Its main limitation is that the maximum side thrust which can be produced is restricted to about 10 percent of the axial thrust if serious losses are to be avoided. If fairly high losses can be tolerated, up to 20 percent side thrust is possible. It would appear that the sleeve will be little affected by erosion.

HIGH REYNOLDS NUMBER TESTS ON A 70° L.E. SWEEPBACK DELTA WING AND BODY (H.P. 100) IN THE COMPRESSED AIR TUNNEL. R. W. F. Gould and C. F. Cowdrey. 1958. 23p. diagrs., photos., tab. ARC CP 387. (Ask for N-64039*)

Values of lift, drag, and pitching-moment coefficients are given for a model of the H.P. 100 delta wing with sharp leading edges and with a body attached, over a range of Reynolds numbers from 1×10^6 to 12×10^6 and at incidences up to 42°. Photographs of the traces of an oil/titanium oxide mixture, on the surface, indicating flow directions, are included. The results show no appreciable scale effect.

Directorate of Guided Weapons Research and Development (Gt. Brit.). A BALANCE METHOD OF MEASURING THE THRUST REACTION OF AN AIR JET. P. N. Rowe. October 1957. 7p. diagrs., tab. D.G.G.W. Report/EMR/58/3. (Ask for N-64041*)

The apparatus described has proved suitable for the purpose required but rather a large number of repeats are necessary if the smallest differences are to be detected. It is obvious that the measurement of air reservoir pressure is the major obstacle to still further improvement of accuracy. There are at least two features of the thrust measuring apparatus which could be improved in a future design. Firstly, it should be possible to suspend the calibrating weights on the nozzle axis at a point below the axis of the rotary joint. Secondly, although air leaks through the rotary joint are only some 2 to 3 percent of the flow through the nozzle, this could be virtually eliminated by the use of labyrinth glands. The present apparatus does not lend itself to these improvements.

Directorate of Guided Weapons Research and Development (Gt. Brit.). LABORATORY METHODS OF MEASURING THRUST. P. N. Rowe. August 1957. 27p. diagrs. D.G.G.W. Report/EMR/58/2. (Ask for N-64042*)

This report discusses the various methods by which thrust can be measured, sets out their various advantages, and surveys apparatus that has been built and used. The survey is concerned only with laboratory apparatus and not with the full-scale testing of "hot" motors.

N-64043*

Directorate of Guided Weapons Research and Development (Gt. Brit.). THE EFFECT OF DIVERGENCE ANGLE ON THE THRUST OF A SUPERSONIC NOZZLE. P. N. Rowe. September 1957. 14p. diagrs., photos., tabs. D.G.G.W. Report/EMR/58/1. (Ask for N-64043*)

This report gives the results of a continuation of a study made originally by Coulter and others. The investigation has extended the range of divergence angle, examined the effect of small manufacturing errors, and made a check on the accuracy of the reported results. A series of nozzles has been tested. All have a rounded entry of 1-inch radius, a 1/2-inch-diameter throat, and a straight conical divergence to give a nominal area expansion ratio of 6.0:1. They are designed to discharge air at a (inverse) pressure ratio of 0.01584, that is, to discharge to standard atmosphere from a reservoir pressure of 928 lb/in.^{2} (abs).

Directorate of Guided Weapons Research and Development (Gt. Brit.). A NOTE ON EMPIRICAL EQUATIONS FOR THE DETERMINATION OF THE THRUST GENERATED BY AN IDEAL SUPERSONIC NOZZLE. P. N. Rowe. September 1957. 3p. tabs. D.G.G.W. Report/EMR/58/4. (Ask for N-64044*)

This note gives empirical equations for calculating the area ratio and the thrust generated by an ideal supersonic nozzle. They are simpler to evaluate than the theoretical equations and, within the range $p/p_0 = 0.01$ to 0.05, give results with an error of less than 1 percent. They are intended to aid those designing rocket motor nozzles and particularly to facilitate calculating the effect of changes in the specific heat ratio.

THE MECHANICAL PROPERTIES OF EN 40c STEEL BAR MATERIAL (HEAT TREATED TO 100 TONS/SQ. IN.) IN TENSION, COMPRESSION AND TORSION. L. W. Derry and A. W. J. Layton. July 1958. 22p. diagrs. MOS S & T Memo. 9/58. (Ask for N-64045*)

Material was supplied to specification En 40c in the form of 1-1/8 inch-diameter bar from which tension, compression, and torsion specimens were machined, heat-treated to 100 tons/sq in. tensile strength and finally ground. Tests were performed to determine various mechanical properties of the material. Stress-strain curves are plotted for tension, compression, and torsion tests. For tension and compression tests, mean values and percentage deviations are calculated. Tangent modulus curves are also plotted.

STABILITY CRITERIA FOR LINEAR EQUATIONS WITH TIME VARYING COEFFICIENTS. P. E. W. Grensted. August 9, 1955. 6p. ARC 17,792; S & C 3032. (Ask for N-64254*)

This note attempts to find the conditions that the rates of change of the coefficients must satisfy in order that Routh's criterion is adequate when applied to the instantaneous values of the coefficients alone. Secondly, a modified Routh's criterion is derived which gives an indication of the effect that the rate of change of coefficients has on the stability of the true solution. The method used is applicable to equations of any order, and the results given here are for equations of the second, third, and fourth order.

HYDRODYNAMIC STABILITY OF THE LAMINAR MIXING REGION BETWEEN PARALLEL STREAMS. N. Curle, National Physical Laboratory. May 9, 1956. 15p. diagr., tabs. ARC 18,426; FM 2400. (Ask for N-64259*)

This antisymmetrical profile is considered by a similar method to that used for jets and wakes. Modifications are required because in this case purely symmetrical or antisymmetrical oscillations cannot arise. The critical R is $(U_1 - U_2)(2\delta_1)/\nu = 25$, where U_1, U_2 are the speeds of the two streams, and $2\delta_1$ is the "displacement-thickness" of the mixing region.

EXPRESSIONS FOR THE DAMPING AND NATURAL FREQUENCY OF LINEAR SYSTEMS. A. T. Fuller and R. H. Macmillan, Cambridge University. August 9, 1955. 15p. ARC 17,793; S & C 3033; 0.1203. (Ask for N-64268*)

Three theorems concerning the values of the roots of polynomial equations are derived by manipulation of the Routh-Hurwitz criteria. When applied to the characteristic equation of a linear system, they yield information on the dynamic constants of the dominant mode. The first theorem gives a test for locating the least negative of the real parts of the roots; the second gives a formula for this real part when its magnitude is small; and the third gives new expressions for the imaginary parts of the corresponding root-pair. Thus the degree of stability of the system

BRITISH REPORTS

may be estimated, and when this is small, the formulas give the natural frequency and the damping of the dominant mode in terms of the coefficients of the characteristic equation; in this condition it is also shown how to determine the dynamic constants of lesser modes in certain cases.

THE RECOVERY OF AN AEROPLANE FROM A HIGH SPEED DIVE. A. D. Young, London University and S. Neumark, Royal Aircraft Establishment. April 19, 1956. 42p. diagrs. ARC 18,390; S & C 3091; Comp. 116. (Ask for N-64368*)

Detailed step-by-step calculations have been made of the recovery with fixed elevator from a high-speed dive for three different aircraft; for these calculations measured wind-tunnel data were used. The aircraft differed markedly in their restoring margin. The calculations demonstrated in all cases an initial, rapidly damped, short period oscillatory phase, a nearly constant value of ρV^2 throughout the recovery, and subsequent to the initial oscillatory phase C_m was small. These results enable three different approximation methods for calculating the recovery after the initial oscillatory phase to be developed.

PERFORMANCE ESTIMATES FOR THE R.A.E. 6 INCH HIGH PRESSURE SHOCK TUBE. B. A. Woods. May 1958. 45p. diagrs., tabs. RAE Tech. Note Aero 2560. (Ask for N-64374*)

Estimates are made of the performance of the RAE 6-inch high-pressure shock tube, with various driver gases, over a range of pressure ratios giving shock Mach numbers from 6 to 22. The calculations are based on a simplified model of shock-tube flow, in which the working fluid (argon-free air) is assumed to be always in chemical equilibrium, and the driver gas (either hydrogen or the products of combustion of a hydrogen-oxygen mixture) is assumed to behave as an ideal gas with constant specific heats. The results are presented in graphical form and comprise charts: (1) showing the changes in state across normal shock waves in argon-free air, (2) giving the relationship between shock wave Mach number and diaphragm pressure ratio under various initial conditions, and (3) showing the aerodynamic properties of the shock-induced flows, both in the uniform-sectioned shock tube and when expanded in a divergent nozzle (a) through an area ratio of 225, and (b) to a flow Mach number of 7.

Advisory Group for Aeronautical Research and Development. A SEARCH FOR DEFINITIONS AND CRITERIA RELATING TO NON-OSCILLATORY DIVERGENCE IN NEAR STEADY FLIGHT CONDITIONS. E. Billion. (Presented at Joint Session of AGARD Flight Test Techniques and Wind Tunnel Panels, Brussels, Belgium, August 27-31, 1956.) August 1956. v, 13p. diagrs. AGARD Report 72T. (Ask for N-47555Y)

Starting from the well-known notions of steady-state aerodynamic coefficients and "weathercock" stability, it is possible to state certain definitions concerning the "nonoscillatory behavior" in the neighborhood of a steady-state flight condition which are applicable to systems having several degrees of freedom and which may be extended in certain ways to nonlinear systems. A practical method for calculating the criteria of the nonoscillatory behavior is proposed, within the framework of the approximation which assumes small linearized motion. Applications of this method are made.

Advisory Group for Aeronautical Research and Development. EXPLORATORY STUDIES OF HYPERSONIC FLUID MECHANICS. Seymour M. Bogdonoff, Princeton University. (Presented at 11th meeting of Wind Tunnel and Model Testing Panel, Scheveningen, Netherlands, July 8-12, 1957.) July 1957. 29p. diagrs., photos. AGARD Report 142. (Ask for N-63640)

Using a helium hypersonic wind tunnel, exploratory studies have been made of the flow over simple two- and three-dimensional bodies at Mach numbers from 11 to 19. Detailed studies of the flow over a flat plate are reviewed and preliminary results are presented for other configurations, including flat plates with flaps, delta wings, base pressure models, blunt models (with and without spikes), and slim cones. Some preliminary results of boundary-layer studies and dissolving models are also discussed. In the particular area of hypersonic fluid mechanics, the helium tunnel has proved to be an extremely valuable tool. Its simplicity and ease of operation have permitted a very wide range of studies to be carried out with relatively small effort. It has provided information on flow phenomena in a Mach number range not heretofore subject to detailed investigation.

Advisory Group for Aeronautical Research and Development. MEASURING IN-FLIGHT THRUST OF A TURBOJET-POWERED AIRCRAFT. W. J. Coleman and D. F. DeSanto, Grumman Aircraft Engineering Corp. (Presented at AGARD Flight Test Panel meeting, Paris, April 21-25, 1958.) April 1958. 38p. diagrs. AGARD Report 197. (Ask for N-64381)

Describes the theoretical formulation of a practical method for satisfactorily measuring the in-flight net thrust of a turbojet-powered aircraft. Discusses basic principles of thrust determination, current definitions, and instrumentation techniques, including details of a traversing tailpipe rake.

N-64382

Advisory Group for Aeronautical Research and Development. FATIGUE OF STRUCTURAL MATERIALS AT HIGH TEMPERATURES. B. J. Lazan, University of Minnesota. (Presented at 6th meeting of AGARD Structures and Materials Panel, Paris, November 4-9, 1957.) November 1957. vii, 27p. diagrs. AGARD Report 156. (Ask for N-64382)

The general nature of the fatigue process is reviewed with special emphasis to progressive fracture and statistical aspects. The engineering factors important in high temperature fatigue are tabulated. Special attention is paid to the effects of mean stress, alternating stress, temperature, and stress concentration. The nature and general significance of creep phenomena which occur under various combinations of cyclic stress and mean stress are discussed. The roles of damping, elasticity, and conventional fatigue properties are analyzed to provide criteria for judging resonance fatigue strength.

UNPUBLISHED PAPERS

Guggenheim Aeronautical Laboratory, California Institute of Technology. A SMALL BARIUM TITANATE TRANSDUCER FOR AERODYNAMIC OR ACOUSTIC PRESSURE MEASUREMENTS. W. W. Willmarth. Prepared for NACA on NACA Contract NAw-6479. May 1957. 23p. diagrs., photos. Guggenheim Aeronautical Lab., Calif. Inst. of Tech. (Ask for N-62854*)

The design, development, and calibration of a small barium titanate pressure transducer for aerodynamic or acoustic pressure measurements are described. The calibration was carried out in a shock tube. A few typical oscilloscope records of the transducer response to shock waves are shown. From the calibration, it was found that the transducer response is uniform from approximately 5 to 50,000 cps and the sensitivity of the transducer is 0.88×10^{-6} volts/dyne/cm^2.

Kentucky Research Foundation. FORMATION AND EFFECTS OF SUBGRAINS IN IRON. William L. Mitchell, Charles S. Crouse, and Roy E. Swift. Final report for period ending May 1, 1958, prepared on NACA Contract NAw-6461. May 1958. 71p. diagrs., photos., tabs. Kentucky Research Foundation. (Ask for N-63552*)

To study the effects of substructure on strength properties, ingot iron, high-purity iron, and a low-carbon steel were prestrained various amounts up to 15 percent and annealed at 100° C intervals from 200° C to 800° C to induce substructure. The specimens were then tested in tension to ascertain the effect of substructure on the mechanical strength of the three materials. These materials were completely recrystallized to remove any substructure in the as-received metals, and any added strength was attributed to substructure formation. The yield strength of specimens containing substructure was observed to be from 50 percent to 100 percent in excess of the yield strength of specimens tested in the fully annealed state.

DECLASSIFIED NACA RESEARCH REPORTS

This is authority for those possessing copies of the following research reports to declassify them from Confidential. Items marked (#) are UNAVAILABLE since they contain obsolete or proprietary information. Effective date of declassification September 3, 1958.

ALUMINUM BOROHYDRIDE - HYDROCARBON MIXTURES AS A SOURCE OF IGNITION FOR A TURBOJET COMBUSTOR. Hampton H. Foster, Edward A. Fletcher, and David M. Straight. February 1955. 24p. diagrs., photo., tabs. (NACA RM E54K12)

The use of 40 percent by volume aluminum borohydride blends with a JP-4 fuel and a mineral oil gave almost as good turbojet-combustor ignition limits as those obtained with the undiluted aluminum borohydride. The 10- and 20-percent blends gave erratic ignition. At -40° F better results were obtained with a mineral oil than with the JP-4 fuel blend. The use of 0.025-inch-diameter capillary tubes on the injection capsules was more effective than tubes of larger diameters (0.075 and 0.20) because they increase the injection duration, thus improving ignition. Aluminum borohydride gave good starts at altitude conditions in an experimental 48-inch ram-jet engine.

AERODYNAMIC DESIGN OF AXIAL-FLOW COMPRESSORS. VOLUME I. Compressor and Turbine Research Division. Edited by Irving A. Johnsen and Robert O. Bullock. August 1956. xii, 406p. diagrs., photos., tab. (NACA RM E56B03)

The first three chapters of vol. I are introductory, providing compressor background information and a design-system foundation for the material of succeeding chapters. Ch. I presents the general objectives and scope of the report on aerodynamic design of axial-flow compressors. The basic requirements of compressors for aircraft gas-turbine engines and the basic objectives of a compressor design system are reviewed in ch. II. A general description of the compressor design system that has been adopted for this report is provided in ch. III. Chs. IV and V review the literature on potential-flow theory and viscous effects in two-dimensional cascades, respectively.

NACA RM E56B03a

AERODYNAMIC DESIGN OF AXIAL-FLOW COMPRESSORS. VOLUME II. Compressor and Turbine Research Division. Edited by Irving A. Johnsen and Robert O. Bullock. August 1956. x, 275p. diagrs., tabs. (NACA RM E56B03a)

The first two chapters of vol. II survey and correlate experimentally obtained blade-element data. Ch. VI summarizes the data obtained in two-dimensional cascades, while ch. VII summarizes blade-element data obtained in annular cascades (compressor rotors and stators). Ch. VIII summarizes the design problem and design techniques in the meridional or hub-to-tip plane, and ch. IX provides simple chart procedures for the solution of this meridional-plane design problem. Methods for the prediction of compressor performance over a range of flow conditions and speeds (off-design operation) are presented in ch. X.

NACA RM E56B03b

AERODYNAMIC DESIGN OF AXIAL-FLOW COMPRESSORS. VOLUME III. Compressor and Turbine Research Division. Edited by Irving A. Johnsen and Robert O. Bullock. August 1956. xii, 364p. diagrs., photos., tabs. (NACA RM E56B03b)

Chs. XI to XIII concern the unsteady compressor operation arising when compressor blade elements stall. The fields of compressor stall and surge are reviewed in chs. XI and XII, respectively. The part-speed operating problem in high-pressure-ratio multistage axial-flow compressors is analyzed in ch. XIII. Ch. XIV summarizes design methods and theories that extend beyond the simplified two-dimensional approach used previously in the report. Ch. XV extends this three-dimensional treatment by summarizing the literature on secondary flows and boundary-layer effects. Charts for determining the effects of errors in design parameters and experimental measurements on compressor performance are given in ch. XVI. Ch. XVII reviews existing literature on compressor and turbine matching techniques.

DECLASSIFIED NACA RESEARCH REPORTS

NACA RM E56C10

EFFECT OF FUELS ON SCREAMING IN 200-POUND-THRUST LIQUID-OXYGEN - FUEL ROCKET ENGINE. Isaac Pass and Adelbert O. Tischler. June 1956. 25p. diagrs., photos., tab. (NACA RM E56C10)

The tendencies of fourteen fuels and three fuel blends to produce screaming were measured in a 200-pound-thrust, liquid-oxygen - fuel rocket engine. The fuels, in order of increasing screaming tendency, are (1) hydrazines (these did not scream at all); (2) branched-chain paraffins, aromatics, and amines; and (3) straight-chain paraffins. This same trend of increasing screaming tendency also correlated with increasing fuel evaporation rate. A hypothesis to explain the trend of screaming tendency with evaporation rate is described. Screaming amplitude varied from 0.1 to 0.5 of the operating pressure, but there were no significant differences among fuels with regard to oscillation amplitude.

NACA RM E58A20a

EFFECT OF FUEL DROP SIZE AND INJECTOR CONFIGURATION ON SCREAMING IN A 200-POUND-THRUST ROCKET ENGINE USING LIQUID OXYGEN AND HEPTANE. Charles E. Feiler. June 1958. 27p. diagrs., photos., tab. (NACA RM E58A20a)

Screaming was most strongly influenced by the general method of propellant preparation. The largest screaming amplitudes were observed with a triplet injector. Fuel drop size apparently was of secondary importance; however, for two injectors differing only in the mean fuel drop size produced, screaming amplitude varied inversely with drop diameter.
